3 When, because of social or economic factors, the patient may discontinue treatment, refuses to wear a brace, has an uncooperative family, etc. The severe fixed deformity—flexion, adduction, and internal rotation of the thighs—which may occur as the result of such neglect should be prevented by prophylactic surgery. As late as 1937-1938 we lost 101 cases from our clinic. Of these, 73 could not even be located in New York City by our social service follow-up and 22 refused to go to any hospital, even though the visits were free.

4 When the patient is mentally deficient and the parents refuse to have him admitted to an institution, although he unquestionably belongs in one. In many instances we have performed an operation such as an obturator neurectomy in

order to separate a child's legs, relieve incontinence of urine, and make bed care at home easier for the mother. In other words, we operated for the sake of the parent.

The advancements that I have spoken of have been made possible largely by the works of such men as Drs Putnam and Phelps, and I should like, in conclusion, to say that it has been a privilege for me to discuss this symposium.

Dr J B L'Episcopo, *Brooklyn*—I want to thank Drs Duryea, Putnam, and Phelps for focusing our attention on a group of cases that has been given little attention by the medical profession, except by a few interested and enthusiastic workers of whom the essayists are representative. There is really little to discuss. All have given us fundamental facts and sound recommendations on how to handle these problems.

Dr Duryea has stressed essentially the socioeconomic and educational phase and has told us how this problem should be met. I am in thorough accord with his recommendations.

Dr Putnam has brought to our attention essentially the purely neurologic management of this problem. Great progress has been made in the last few years along these lines. I feel certain that with a better understanding of the physiology and the pathology of these conditions greater progress should be made in the near future.

I think we are particularly indebted to Dr Phelps for clarifying the picture between the true spastic and the athetoid as they affect children. He has properly stressed the study of visual, oral, and sensory disturbances in these children before rating their intelligence, for the mentality of each child will determine the prognosis and treatment that should be given.

It has been mentioned that some of these patients may be treated in the outpatient department of properly equipped hospitals. Although this may have to be done for lack of facilities and practical purposes, I believe that all these patients should be treated in special institutions. At least the early part of the treatment should be given in the hospitals before

relegating the milder forms to the outpatient department. It has been stated that a minority of these spastic children have such a low mentality that treatment is practically impossible. This minority group should be placed in institutions for custodial care. Such institutions, as far as I know, are now sadly lacking in New York State. I believe that the state should provide proper institutions for these defectives.

With our present knowledge of spastics, I believe that the best classification would be one based on the physiology or according to the motor control—that is, mild, moderate, and severe. The prognosis, I believe, is good, except in the severe cases. In order to treat these patients properly, the so-called spastic must be differentiated from the athetoid type. We must also recognize the different degrees of paralysis and the possible overlapping of spastic and athetoid forms. I agree with Dr Phelps in all his orthopedic recommendations except the procedure of tenotomies, unless he wishes to destroy the action of the tight muscle involved. This is particularly to be avoided in the tendo achillis. I have seen a calcaneus deformity develop after tenotomy of this tendon for correction of equinus deformity. A calcaneal gait is much more disabling than one of equinus. We prefer to do a tendon lengthening to overcome this muscle contracture.

Finally, we should not assume a too pessimistic attitude toward these children. The great majority can be rehabilitated to useful citizenship or to a condition whereby they may take care of their own wants and not be a burden to their family or the community. This can be accomplished by a combination of proper educational and therapeutic management. The minority whose mentality is poor should be placed in institutions for permanent care. These institutions are now lacking and should be made available.

I want to thank Dr Duryea, Dr Putnam, and particularly Dr Phelps for their pioneer work in this field which has stimulated the interest of many people concerned in this problem, particularly educators and the medical profession.

THE PHYSICIAN AS A PSYCHOLOGIST

The physician must train himself to be a practical psychologist so that he may quickly fathom the unspoken reactions of the patient which are frequently more outspoken than uttered words but which may entirely escape the unwary. It is important that this appraisal be instantly accomplished, for the ensuing procedure may be dictated by a fleeting impression. The ability to delve into the psychic reactions of the patient and often to anticipate unexpressed reactions is frequently referred to as intuition. It comprises no mystic powers but only the alert interpretation of subtle expressions, both uttered and un-

uttered. As the physician is usually the interrogator, he should always attempt to command this advantage. The approach to each patient necessitates a variation in technique, and it is frequently important to engage the individual in general conversation before bluntly plunging into the presenting problem. Many times the alert physician obtains invaluable clues regarding the patient before a word of the individual's physical complaint has been stated.—*F A Willius, M D. A Talk on the Science and the Art of Medical Practice, Proc Staff Meet, Mayo Clinic, 15 649 (October 9) 1940*

TREATMENT OF THE HYPOCHONDRIAC

ROBERT B. MCGRAW, M.D., and ZYGMUNT PIOTROWSKI, Ph.D., New York City

IF SICKNESS insurance is forced upon the medical profession, the hypochondriac will take up considerable time and energy from the practitioner. Certain hypochondriacs are intellectually inferior, and they should be treated somewhat differently from the intellectually superior individual.

In the hypochondriacal reaction, as we for the present define it, there is great increase in self-observation, concern about the individual's health, and a change in somatic sensations. This reaction, combined with an inferior intelligence, leads to the development of complicated and variable complaints on the part of the patients. Such people usually shop around at various clinics. This, as well as the fact that they show many symptoms that cause them to be put through a great deal of expensive procedure, makes the cost of treating them quite high. They take up time that could be much more profitably spent with other patients. They are frequently querulous, easily disgruntled, and sometimes litigious. One of us (McG.) has been aware of this problem for fourteen years. The 50 patients for whom statistical data have been computed are a random sample of a larger group of patients treated at Vanderbilt Clinic.

Data

These 50 patients included 13 men and 37 women. The average age at admission to the Columbia-Presbyterian Medical Center was 32 years. On the basis of psychologic examinations,* 10 of them were of dull-normal intelligence, 12 were of borderline capacity, 21 were high-grade defective, and 7 were low-grade defective. Nine of these patients came directly to the Department of Psychiatry. The remaining 41, however, had been treated in a number of different departments for the average time of twenty-eight months before they came to the Department of Psychiatry, and during that period they had shown no improvement in symptoms and subjective complaints. The average number of departments which these patients visited in the Medical Center was 4.3 for the men and 6.8 for the women, or 6.1 for the entire group. The total

average time during which the patients received treatment was forty-seven months or nearly four years. The average time during which they were carried in the Department of Psychiatry was fourteen months.

These statistical data show the tremendous expenditure of time which these patients required without its bringing about any appreciable change in their condition.

Treatment

These people are a great burden not only to the public treasury but also to themselves and to others. There is no doubt that they need to have a person or a clinic that will maintain some interest in them. This interest, however, need not be extreme or time-consuming. Therefore, the suggestion is made here of a plan of treatment that would not only shorten the time of treatment and save a great deal of wasted energy but might also be of greater benefit to the patient.

The most important point to keep in mind seems to be that these patients need simple treatment. Complicated treatments, explanations, numerous tests, etc., are not only expensive but actually harmful, for these patients are confused and bewildered by them. It is particularly important to be careful about the introduction of physical therapy, because these patients will demand it for a long period of time, especially if it is agreeable. The chief difference between a therapeutic approach to these patients and a similar approach to patients of average or high average intelligence consists in the inability of the intellectually inferior patients with hypochondriacal reactions to follow normal reasoning. These patients need a general approach and have to be treated largely on the somatic level. They must not be overtreated. Deep psychotherapy seems to be impossible with them. Suggestions by the doctor, medication or diet, and simple explanations of hygienic measures seem to be most effective. If these patients are recognized, treatment should be centered in one department of a clinic if at all possible. Radical cures are not obtained, but amelioration and stabilization are frequent.

These patients are not difficult to diagnose. Their hypochondriacal complaints are easily recognizable, and in the vast majority of cases (if they are treated in large clinics) their records

*From the Department of Psychiatry, College of Physicians and Surgeons, Columbia University, and the Vanderbilt Clinic.

*Dr. Roy F. Street gave psychologic examinations to some of these patients in the years of 1929 to 1931.

order to separate a child's legs, relieve incontinence of urine, and make bed care at home easier for the mother. In other words, we operated for the sake of the parent.

I want to thank Dr. Duryea, Dr. Putnam, and particularly Dr. Phelps for their pioneer work in this field which has stimulated the interest of many people concerned in this problem, particularly educators and the medical profession.

THE PHYSICIAN AS A PSYCHOLOGIST

The physician must train himself to be a practical psychologist so that he may quickly fathom the unspoken reactions of the patient which are frequently more outspoken than uttered words but which may entirely escape the unwary. It is important that this appraisal be instantly accomplished, for the ensuing procedure may be dictated by a fleeting impression. The ability to delve into the psychic reactions of the patient and often to anticipate unexpressed reactions is frequently referred to as intuition. It comprises no mystic powers but only the alert interpretation of subtle expressions, both uttered and un-

uttered. As the physician is usually the interrogator, he should always attempt to command this advantage. The approach to each patient necessitates a variation in technique, and it is frequently important to engage the individual in general conversation before bluntly plunging into the presenting problem. Many times the alert physician obtains invaluable clues regarding the patient before a word of the individual's physical complaint has been stated.—*F. A. Williams, M.D. A Talk on the Science and the Art of Medical Practice, Proc. Staff Meet., Mayo Clinic, 15 649 (October 9) 1940*

her condition, and her symptoms shifted from place to place. In 1930 a Stanford-Binet showed a mental age of 7 years and 7 months, with a chronologic age of 34 years. Attention was hard to secure and of short duration. Whenever a task was presented that was too hard, she developed marked respiratory difficulty and would gasp for breath. Subsequently, it was felt by an outside agency that she could not take care of her baby and that her 9-year-old daughter made her irritable. In view of her markedly low I Q and her difficulties in adjustment, institutional care was suggested, but this was rejected by the patient's relatives.

The case came up for reconsideration four years later, at which time she complained that her head had changed its shape and that her mind was affected. She said she could not control her feelings and smashed dishes and furniture. During an interview she wept continually and complained of headache, dizziness, and loss of speech, though her voice remained steady and distinct. Another psychometric examination gave a mental age of approximately 8 years with an I Q of 53. This was done about five years subsequent to, and is in general agreement with, the first examination.

This patient was treated in a great many different hospitals and in the following departments of the Vanderbilt Clinic: gynecology, otolaryngology, urology, varicose veins, ophthalmology, physical therapy, orthopedics, general surgery, neurology, and psychiatry. As far as we know she is still going to different hospitals and clinics and is receiving no particular benefit therefrom.

Case 4—This is a case of a veteran of the World War, about 40 years of age, who is said to have been a tailor before military service. He made his first visit to the Vanderbilt Clinic in the early part of 1929, and the case was closed in 1934. His past history included an injury and an operation on his right foot when a child. He started school at 5 and stopped at the age of 9, was apprenticed to a tailor, and worked until the age of 17. He came to the United States at that time. He states that he went to night school and joined the Army when he was about 26.

He was a patient in a Government hospital the latter part of 1930 and the early part of 1931, a total of about four months. It was considered that he was a severe psychoneurotic. He complained of headache and pain in his abdomen. It was later determined that he had blurring vision, which was felt to be due to a retinitis of unknown cause. There was cellulitis of the right foot. Later in 1931 he was readmitted for a matter of about six weeks in a Government hospital and complained of pain in the right eye, headaches, and pain in the intestines. While under observation there, a phlebitis of the right leg was discovered. It was felt that he had definite retinitis of both eyes and also a severe psychoneurotic reaction. Following his discharge from the hospital he came to Vanderbilt Clinic, ap-

parently being dissatisfied with the care given him. It was here determined that he had a mental age of 7 years and 3 months, with an I Q of 51 on a 14-year base. He apparently had definite organic difficulty but also a superimposed psychoneurosis, which seemed definitely related to his defective intelligence. His eye condition improved but his mental condition remained fairly stationary. He was directed back to the Government organization for the relief and treatment of veterans, and he was closed to this clinic. Two years later a follow-up indicated that there had been no improvement but that the organization was still caring for the patient.

Determination of Mental Defect

In order to apply the suggested plan of handling these patients, it is important to ascertain whether a serious mental defect is present. A complete psychometric survey of patients of this type by a qualified psychologist is not always possible, nor is it advisable. These patients universally resent any examination that implies a mental abnormality on their part and are frequently thrown into a panic when placed in the formal testing situation. A few simple questions asked rather casually by the physician should suffice to aid in diagnosing mental deficiency. A careful analysis of the reactions of our patients would indicate that the following test questions, if failed by the patient, reliably permit the conclusion that his intelligence is markedly inferior. The questions all form part of the well-known Binet scale and have been chosen because of their selective value for this particular type of patient. The scoring of these questions, however, differs in many instances from that suggested by Terman. These changes have been made on the basis of experience with our 50 patients.

(1) *Interpretation of Fables*—These are Aesop's fables, the same ones used in the Stanford-Binet test. The method consists in saying to the patient: "A fable, you know, is a little story and is meant to teach us a lesson. Now, I am going to read a fable to you. Listen carefully and when I am through, I shall ask you to tell me what lesson this fable teaches us." Then read the first fable and ask: "What lesson does that teach us?" It is important to make certain that the patient actually recognizes the difference between the literal and the abstract meaning of the fable. Many people have had these fables in school and have ready-made responses, the meaning of which they do not realize. It is therefore imperative to ascertain that the abstract meaning is grasped clearly. The physi-

reflect their personality plainly. The "unit history" is, therefore, particularly useful.

Case Reports

Case 1—This patient, a meek, sickly looking Jewish woman, who spent the first fourteen years of her life in her native Russia, and the next five working in a factory in England, came to the United States at the age of 19. She married soon thereafter. Economic conditions have always been difficult. The patient has always been accustomed to think of herself as unable to lead a normal active life. She has been fairly comfortable during the past few years by taking good care of herself and does not appear to resent her lack of activity. She has been greatly depressed and fears she is about to die. She feels keenly disappointed over not having children, there were no pregnancies.

The patient first came to the Vanderbilt Clinic at the age of 47 with a complaint of epigastric pain. She had had an appendectomy and a resection of a cystic ovary twenty years earlier, following which her condition had been considered cured. Five years before admission to the Vanderbilt Clinic, she had been operated on for adhesions of the omentum to the abdominal wall and had been discharged as improved. She had been complaining of pain in the epigastrium for the period since the operation for adhesions, having lost 55 pounds during this time.

A psychologic examination at the time of admission revealed a mental age of 7 years and 9 months, with a corresponding I Q of 52. She has had no schooling whatsoever. During the past five years the patient has visited nine departments in the Vanderbilt Clinic, making a total of 126 visits, not counting several hospitalizations. Among the departments visited were neurology, psychiatry, urology, surgery, and gynecology. A pelvic examination revealed a mild degree of vaginitis in the external quarter of the vagina. An x-ray of the genitourinary tract, following complaints on the part of the patient, revealed a possible stone in the right kidney, but operation was considered unwise in view of the patient's personality. The patient's gastric complaints were so persistent that she was operated on for an ulcer, which was not found. Her subjective complaints remained the same. After she had been seen by many physicians, despite the negative nature of the laboratory findings, all the nonpsychiatric departments also came to the conclusion that they were dealing with a hypochondriacal mental defective who would not be benefited by further surgical manipulations.

Case 2—This patient was known to the Neurological Institute when she was 14 years old. The complaints at that time were uncontrollable temper, throwing objects at members of the family, imagining that people on the street spoke of her as a "bad girl." It was thought that she was

a psychotic, and no treatment was given. At the age of 29 this patient came to the Department of Psychiatry, Vanderbilt Clinic, with the same complaints. She was unstable, anxious, quarrelsome, aggressive, and difficult to manage. Her condition was complicated by a chronic otitis media and a chronic pharyngitis, over which she was much concerned. The patient was treated in the departments of psychiatry and otolaryngology. In the beginning, she was seen regularly in the clinic, later, the intervals between visits grew longer. She usually presented a problem of management, becoming involved as she did in fracas with other patients. She looked upon her visits to the clinic as a treat and came whenever possible.

She underwent a psychologic test at the age of 19, following which her family was told that she had a maximum mental age of 8 years. When she was 29, her Stanford-Binet mental age was 7 years and 7 months, and the performance tests were failed even more conspicuously. At the age of 32, her Stanford-Binet mental age was 7 years and 2 months. Her relatively best achievement was fluent verbalization. The corresponding I Q's for these two examinations were 51 and 48, respectively. The patient was diagnosed as a mental defective and, because of the seriousness of the deficiency, as well as because of her uncontrollable and aggressive behavior, institutionalization was suggested to the family. Her parents did not follow this advice because they felt that the patient's symptoms were temporary. Treatment of her mild somatic condition was extremely complicated by her misunderstanding of directions. The patient continually asked for special examinations in the various departments. The resultant positive findings consisted of impaired hearing, impaired vision for which glasses were prescribed, and defective teeth, which were treated at the clinic. The patient was treated simultaneously in several different departments. She was repeatedly referred to psychiatry by the other departments because of the negative findings in the presence of persisting complaints. The patient has been coming to the Vanderbilt Clinic for nine years. Her mental condition has remained unchanged throughout the entire period. In fact, it has been the same since the age of 14, i. e., for the past twenty-four years.

Case 3—This patient on admission, an obese, 28-year-old woman, complained of pain in the back and stomach for the past four years. Menses were regular but were accompanied by abdominal pain. She had had one child and one miscarriage. There had been an operation for peritoneal adhesions one year before, a similar operation seven years before, and an appendectomy nine years before. The patient believed that she had had gallstones and that these were removed at one of these operations.

It was apparent on examination that this patient would not be able to get much insight into

2-8-3	6-5-2-8	8-1-3-7-9
4-2-7	4-9-3-7	6-9-5-8-2
9-5-8	8-6-2-9	5-2-9-4-1

The test is considered failed if the patient is unable to repeat five digits backwards correctly in three trials. It is advisable to begin with the three- or four-digit group.

Our experience has shown that if a patient fails three out of the four tests described above mental deficiency can be reasonably suspected.

180 Fort Washington Avenue

ARMY MEDICAL CARE

If a member of your family has been called for duty in the U S Army, you may have wondered sometimes as to the provisions made for taking care of the health of the soldiers in the rapidly growing armed forces.

Youths inducted under the Selective Service Act are given thorough physical examinations before acceptance in the army, and candidates for commissions as "flying cadets" undergo even more rigorous tests. So the boys in the army are a pretty healthy bunch to begin with.

And once in the service, they are provided with the best in medical attention. The *New York State Journal of Medicine* recently sent its editors on a tour of inspection of army posts and camps in this state, and the inspectors returned with high praise for the excellent medical care provided army men.

"Hospitals are adequate in size and well equipped with the most recent mechanical, electrical, and other professional apparatus," say the editors. "Drugs and other expendable supplies are well stocked. The hospitals are being conducted with well-organized services in medicine and surgery and with most of the special services, such as eye, ear, nose and throat, urology, x-ray, psychiatry, well represented."

"The staffs are in most cases up to full complement. Everywhere we observed a great alertness and enthusiasm for their work on the part of the personnel, both officer and enlisted. It is a tribute to the profession and to the high quality of their training that, considering the short length of time they have worked together, the morale, teamwork, and overall efficiency of the staffs are at once noted by the observer."

"Cases are disposed of either by admission to the hospital or return to 'quarters' or 'duty.' There is no status of 'light duty.' The army's policy is that a soldier is either fit for duty or should be hospitalized, the carrying of patients 'in quarters' is discouraged."

The editors point out that venereal disease in the army appears to be decreasing as a result of cooperation between military and civilian authorities.

The whole report seems to add up to this—the youth in the army has medical service provided for him which is just about the equal of the best and costliest obtainable in civilian life.

—*Salamanca Republican*,
Aug 6, 1941

Summary

A group of mentally defective patients is presented. It is believed to be representative of a large class and is felt to be important from the general medical, social, and economic standpoints. They present somatic complaints for which they need treatment. Treatment should be simple and objective, and radical cures should not be expected.

THE DOCTOR AND THE DRAFT BOARD

Local draft boards have received a bulletin from state headquarters of the Selective Service containing suggestions dealing with the deferment of medical doctors and interns.

The bulletin points out that the national defense program as now outlined will require 7,900 physicians for the army, 900 for the navy and 200 for public health service and Veterans' Administration, a total of 9,000 physicians in addition to the present staffs. This demand, if filled, would mean a 5 per cent reduction in the number of physicians in the nation.

In addition to the demand for medical doctors in various branches of the armed forces and public services, it is estimated that the development of new communities, increasing industrial activity, and other conditions arising from the defense program will cause a demand for an additional 10 per cent of the supply of doctors.

There is, and will continue to be during the national emergency, an increasing demand for medical doctors, the bulletin states.

It is estimated that approximately 5,000 students enter medical training courses each year and that about 3,800 physicians are lost to the profession each year due to natural causes. The headquarters charges the local boards with the responsibility of deciding whether an individual doctor should be deferred in the draft and asks that consideration be given the matter with the overall situation in mind. It also states that if the board finds that he should not be deferred because of any pressing need of his services in the community, his attention should be called to the opportunity that he has to secure a commission in the Medical Reserve Corps.

The bulletin says that since the supply of doctors must be encouraged the local boards are advised that no student or intern who gives reasonable promise of becoming an acceptable medical doctor be called to military service before attaining that status. Interns who meet the army physical standards can be commissioned in the Medical Reserve Corps and, if so commissioned, will not be called to active duty during the first year of internship. Consequently, even though a local board places an intern in Class 1-A by reason of determining that he can be spared from the community, such intern may, by becoming a member of the Medical Reserve Corps, complete his first year's internship.

cian should refrain from crediting the patient with meaning and associations which he himself has with these fables. It occurs frequently, for instance, that the defective patient will interpret the fable of the Milkmaid to mean "Don't count your chickens before they are hatched." If pressed to be more specific, he discloses that he really did not get the point at all, literally thinking of counting the chickens. If the patient fails to give the meaningful abstract interpretation of three or more of these fables, mental defect is probable.

(a) *Hercules and the Wagoner*—A man was driving along a country road, when the wheels suddenly sank in a deep rut. The man did nothing but looked at the wagon and called loudly to Hercules to come and help him. Hercules came up, looked at the man, and said "Put your shoulder to the wheel, my man, and whip up your oxen." Then he went away and left the driver.

(b) *The Milkmaid and Her Plans*—A milkmaid was carrying her pail of milk on her head, and was thinking to herself thus: "The money for this milk will buy 4 hens, the hens will lay at least 100 eggs, the eggs will produce at least 75 chicks, and with the money which the chicks will bring I can buy a new dress to wear instead of the ragged one I have on." At this moment she looked down at herself, trying to think how she would look in her new dress, but as she did so the pail of milk slipped from her head and dashed upon the ground. Thus, all her imaginary schemes perished in a moment.

(c) *The Fox and the Crow*—A crow, having stolen a bit of meat, perched in a tree and held it in her beak. A fox, seeing her, wished to secure the meat, and spoke to the crow thus: "How handsome you are! And I have heard that the beauty of your voice is equal to that of your form and feathers. Will you not sing for me, so that I may judge whether this is true?" The crow was so pleased that she opened her mouth to sing and dropped the meat, which the fox immediately ate.

(d) *The Farmer and the Stork*—A farmer set some traps to catch cranes which had been eating his seed. With them he caught a stork. The stork, which had not really been stealing, begged the farmer to spare his life, saying that he was a bird of excellent character, that he was not at all like the cranes, and that the farmer should have pity on him. But the farmer said: "I have caught you with these robbers, the cranes, and you have got to die with them."

The patient is considered to have failed this test when on further questioning he merely repeats the content of the fable, gives an inadequate generalization or a literal interpretation. Examples of the latter are "Don't drive on bad roads" to fable (a), "Don't carry

milk on the head" to fable (b), "Don't open your mouth when you are eating" to fable (c), or "Don't trespass" to fable (d). Only the following interpretations and their logical equivalents should be scored as correct: To fable (a) "Don't depend on others", to fable (b) "Don't take for granted what is a mere possibility", to fable (c) "Don't believe people who flatter you", to fable (d) "Beware of bad company."

(2) *Logical Hierarchy*—In this test the patient is required to find a generic term which would comprise all the three concepts named. Say to the patient: "I am going to name three things that are alike in some way, and I want you to tell me how they are alike."

- (a) Snake, cow, sparrow
- (b) Book, teacher, newspaper
- (c) Wool, cotton, leather
- (d) Knife blade, penny, piece of wire
- (e) Rose, potato, tree

Correct would be to give a generic term such as animals for (a), pertaining to education for (b), materials to wear for (c), metal for (d), and plants for (e). Three responses passed out of five are necessary to consider the test a success.

(3) *Absurdities*—Say to the patient: "I am going to read a sentence which has something foolish in it, some nonsense. I want you to listen carefully and tell me what is foolish about it."

(a) A man said: "I know a road from my house to the city which is downhill all the way to the city and downhill all the way back home."

(b) An engineer said that the more cars he had on his train the faster he could go.

(c) Yesterday the police found the body of a girl cut into eighteen pieces. They believe that she killed herself.

(d) There was a railroad accident yesterday but it was not very serious. Only forty-eight people were killed.

This test is considered completely passed if the patient detected the absurdity in four out of the five statements in a manner excluding doubt.

(4) *Digits Backwards*—Say to the patient: "Listen carefully. I am going to read some numbers. I want you to say them backwards. For example, if I should say 1-2-3, you would say 3-2-1. Do you understand?" When it is certain that the patient understands, say: "Ready now, listen carefully and be sure to say the numbers backwards." The digits should be read to the patient in a clear voice at the rate of one digit per second.

Partial and full body packs are also used as well as the arm bath of increasing temperature.³ The steam jet is of great value for the relief of anal spasm.³

Light therapy, especially radiant heat, is also of value to induce relaxation. Convulsive heating by means of short-wave or conventional diathermy here have broad application. Brunner⁴ applies diathermy for esophageal spasm using internal electrodes. We have used diathermy to the celiac plexus in the treatment of gastrointestinal spasm. Diathermy to the precordium is extensively used for sedative effect in the treatment of degenerative heart disease in which the relief of symptoms is sometimes spectacular. Autocondensation has long been used in the treatment of arterial hypertension. Diathermy application has also been used in the treatment of insomnia, and here the comfort of the treatment and the hum of the machine are probably the principal factors. Low-voltage currents also contribute to the promotion of relaxation. Bettmann⁵ has applied sinusoidal stimulation to the extremities and improves circulation by relieving vascular spasm. Mandelbaum⁶ has applied sinusoidal current to the esophagus for the relief of esophageal spasm. Sinusoidal stimulation has also been used for suppression of diaphragmatic spasm by treatment of the phrenic nerve. Goodman⁷ has accomplished the same end by refrigeration of the phrenic nerve.

Mechanotherapy in the form of massage, particularly in the form of superficial stroking, is markedly effective to produce relaxation. The role of exercise will be discussed in detail later. Stoll⁸ secures muscular and nerve relaxation by improving the posture and function of the temporomandibular joint.

Acoustic stimuli play an important role in relaxation. Following the suspension of operation of the elevated railroads in New York City there were many complaints of insomnia due to absence of the accustomed noise. However, it is our opinion that these people had been sleeping in a state of neuromuscular hypertension, but now that they rest in quiet they will get much greater benefit from their sleep when they have become accustomed to the absence of the roar of the trains. Some noises we definitely recognize as soothing, such as the murmur of a brook and the calming influence of soft music.

In the previous discussion we have shown that therapeutic relaxation may be accomplished by a great variety of the applications of physical medicine. We will now consider

active methods of producing the same result—methods in which the training of the patient plays a most important part.

Jacobson,⁹ of Chicago, has published an interesting method for producing relaxation of neuromuscular hypertension. He teaches his patient to become acquainted with the concept of tension by letting him contract certain isolated muscle groups. By consciously releasing this tension, the patient is taught the sensation of relaxation. This method has proved to be valuable in many cases. However, it is difficult to teach, and it demands long and exacting cooperation of the physician and patient. Jacobson achieves relaxation with the help of the patient's volition, which introduces the factor of mental activity. We have sought a method to produce relaxation without the conscious cooperation of the patient.

In this country and abroad much experience has been reported in accomplishing relaxation by influencing the respiratory system. It may readily be demonstrated that shallow or incorrect breathing will produce tension. Incorrect breathing affects the circulation and the sympathetic nervous system through the respiratory center. It causes tension in all muscle groups that participate in respiration, because these muscles do not relax sufficiently during exhalation. Thereby, a certain residual tension remains in these muscle groups which, reflexly, is transmitted to other muscles, particularly those of the shoulder girdle and the lower back. Here we have the inception of postural changes that ultimately will involve even the posterior muscle groups of the legs. The muscle tension thus established further aggravates the causative factors and the vicious cycle already mentioned has been established. Circulatory changes will also occur due to decreased negative pressure in the thorax, which impairs venous return.

Shallow breathing combined with impaired circulation reduces oxygenation of the blood. The tissues of the body suffer in consequence, further tension develops, and another vicious cycle has been established. From the above the importance of correct breathing becomes apparent.

Since incorrect breathing forms a link in these cycles, it would seem logical to make our attack at this point. As already mentioned the use of breathing exercises in therapy is by no means new. Crampton¹⁰ has recommended it for the treatment of arterial hypertension, to increase the mobility of the chest, to further thoracic respiration, to relieve abdominal

THERAPEUTIC RELAXATION

H J BEHREND, M D , and JEROME WEISS, M D , New York City

IN PRESENTING the subject of therapeutic relaxation we wish to emphasize that the topic is far from a new one. It is our purpose here to review the multitude of methods that have been utilized to secure relaxation, to correlate these methods, and to establish criteria that will facilitate their more extensive application. The general conception of relaxation therapy both to the physician and the layman is some system of rest and exercise. Although this does comprise a large part of the subject, few realize that the success of many entirely different forms of treatment is secured by promotion of relaxation. Many functional and organic disorders follow a cycle or chain of events. Almost without exception one link of this chain is a condition of increased tension in some form. Breaking of this link by suitably selected and directed therapeutic relaxation is the logical course to follow.

Tone is an essential feature of all living tissue. In health a normal tone is recognized. Deviation from the normal can occur in either direction. Decrease in tone results in the state variously described as atony or hypotonia. Increase in tone constitutes a hypertensive state. It is with the latter condition that we are chiefly concerned in this presentation. We must not confuse hypotonia with fatigue, as is very well described by Rathbone.¹

The question will naturally arise as to the dividing line or normal tonus. When does muscle tone become muscle tension? When does nerve or mental tone become nerve or mental tension? No sharp point of demarcation can be established between these states because the normal tone varies with physiologic requirements.¹ However, we can recognize two extremes. A flaccid type lacking in tone and the so-called "nervous" type with abnormal tension of muscle or nerve. Between these two is the normal or optimum condition—normal muscle, nerve, and mental tone.

Deviations from the normal may be considered as primary and secondary. Primary deviations may be due to racial or individual characteristics. Some races are notoriously

"high-strung", others are definitely phlegmatic. However, individual variation is observed in which an individual may differ widely in muscle and nerve tone as compared to others of the same general racial group. Among secondary factors we must consider environment and training as the most important. Damage to nerve or muscle tissue by accident or as the result of illness or toxins, either endogenous or exogenous, must also be considered. It is the trained physician who must recognize the hypertensive state in his patient, evaluate its influence upon health and illness, and administer the proper therapeutic measures. Diagnosis at times is apparent, at other times it is obscured by a combination of functional and organic disturbances. The patient with esophageal obstruction may be suffering from the inroads of a carcinoma or he may have nothing but an esophageal spasm.² Only the physician is competent to distinguish between the functional and the organic disturbance. Even in certain organic lesions relaxation therapy is of value as an adjunct to other treatment.

Therapeutic relaxation is in far more general use than is at first apparent. Often, it is encountered in a totally unrecognized form. In reviewing briefly the various forms and applications of therapeutic relaxation, we must exclude all reference to drugs and psychotherapeutic methods, because on these alone volumes could be written. We will confine ourselves here to consideration of only purely physical methods.

Rest is a valuable means of promoting true relaxation. Unfortunately many people have a strange conception of what constitutes rest. We are familiar with the spectacle of the vacationer returning weary and far from being fit to resume his work. In ordering rest the doctor must impress his wishes upon the patient and not leave the matter to the latter's discretion. Rest as considered above constitutes a readily recognized form of therapeutic relaxation. We must now consider many forms that are not so easily recognized. The objective of many physical therapy measures is to secure relaxation. In hydrotherapy we utilize the warm bath and the continuous warm baths as frequently used in mental institutions.

the type of the shallow breather. Many, fortunately, do not complain except of perennial aches and pains which they would probably miss if they were relieved of them.

2 The second group comprises those shallow breathers who have developed definite complaints. It should be mentioned here that the normal baby is a true normal breather. This normal breathing is lost in later life for many important reasons:

a If the baby sits up too early and develops a postural deformity

b Bad habit formation in preschool age

c During school age

Extended periods of desk work and carrying of heavy books

d In later life those in sedentary positions will deviate from normal breathing and even those indulging in athletics and sports may develop hypertensive states especially when in competition.

The clinical symptoms observed in these individuals are headache, pains around the shoulder girdle, chest pain, sometimes diagnosed as angina pectoris or athlete's heart, and abdominal pain, sometimes diagnosed as a chronic gallbladder condition, or even an acute appendix, and treated accordingly. Low back pain with all its consequences and foot and leg disabilities too numerous to mention have also been encountered in these cases.

Following extensive study of the subject we have established a technique for our breathing exercises. We wish to express our indebtedness to physical instructor Karin Roon for her excellent cooperation in preparing this paper. We have incorporated her technique in our system of exercises which have given gratifying results.

The patient in his exercise suit is placed on a cushioned table in a comfortable dorsal recumbent position. He first exhales blowing through the pursed lips. This must be done without effort. Pursing of the lips is important as it has a remarkable effect upon the action of the abdominal muscles. The patient must now rest quietly and wait until natural inspiration occurs. This is an essential feature, and sometimes a difficult one, for the patient to master. From this point on, the instructor will do well to demonstrate to his patient by performing the correct breathing technique himself. In order to do this he naturally must be trained to do it properly. By placing his hand upon the operator's chest the patient can note the difference between the harsh intermittent breathing so often encountered and the smooth undulating breath-

ing which is so desirable. Only by this method can we quickly accomplish the establishment of correct breathing which will lead to true relaxation. Supervision must be continued until the patient senses the pleasant calm induced by the passive breathing.

When properly performed, the inspiratory wave starts at the umbilicus and spreads to the pubis. Only then does it spread upward to the costal margin and, finally, to the chest cage. Exhalation then follows with the lips pursed as before. Our breathing exercise is as simple as this. To establish complete relaxation, we must examine the patient to determine whether any muscles are embarrassed in their function because of impaired antagonist muscles. Suitable treatment must be instituted to correct this condition. Particular attention must be paid to the lateral muscle of the chest and those of the back. In many cases unusual tension of the muscles controlling the costal margin is observed. This can be remedied by suitable training to increase the lateral excursion of the ribs.

In some cases of emphysematous type or barrel chest, uneven excursion of the chest wall may be noted. Movement of the lateral portions may be excessive. Equalizing the movement of the chest cage will often clear up symptoms of cardiac involvement which, thereby, prove to have been functional.

Therapeutic relaxation as established by this simple breathing exercise has given relief in a surprising number and variety of clinical conditions. Whenever the diagnosis of neuromuscular hypertension has been established, therapeutic relaxation is indicated. The benefits are not limited to functional cases but can be obtained even in the presence of organic disturbances. Thus it is of value in the treatment of many resistant diseases such as arterial hypertension, bronchial asthma, and low back pain, to name but a few.

stasis, and to give abdominal massage Tiralla¹⁰ also has suggested breathing exercises as an important therapeutic measure in the treatment of arterial hypertension. He has classified his patients into three groups: one group having pure hypertension with no serious demonstrable changes, another group with beginning changes in the heart, kidneys, and blood vessels, and a third group showing severe changes of the various organs. Systematic deep breathing was effective even in those cases where the heart, blood vessels, and kidneys were involved. His orthodiagnostic x-ray studies have shown that a dilated heart actually can be considerably decreased in size.

Sturm and Paffe¹¹ have followed up Tiralla's work and report that the depressor effect of respiratory exercise is detectable after several weeks or even months. Tonosphygmographic determinations showed that in essential and nephritic hypertension a fall of blood pressure and a diminution of the vascular tonus were observed after breathing exercises of a few weeks' duration. Krohne¹² has recommended breathing exercises for the treatment of bronchial asthma to restore elasticity of the thorax, which has been impaired by decreased mobility, and also influence mechanically the circulation and the abdominal organs.

Corner¹³ once said that as the brain is the organ of the mind and the center of intellectual education, so is the chest the organ of bodily vigor and the center of physical culture.

Experience has shown that we can produce relaxation by improving the respiration.

Breathing exercise, as compared with Jacobson's technic,¹⁴ may be freed from the activity of thinking. We prefer to develop the natural instinct of the individual. Every individual originally establishes his own particular breathing rhythm. It is our task to detect this rhythm and to restore it in case it has been disturbed by habit formation or by disease. We must admit that we have only limited means to describe theoretically the breathing function and the relaxation that may be produced thereby. In looking over the textbooks of anatomy and physiology we find that opinion as to the so-called breathing muscles varies greatly. Up to the present it has not been decided whether the internal intercostals are muscles of inspiration or expiration.¹⁵

Through practical experience and study of the results we have achieved with this form of therapy, we are of the opinion that there is

no fundamental difference between male and female breathing such as is described in some textbooks.

Respiration should be called normal when all muscle groups involved perform their physiologic function perfectly. They must contract and relax in coordination and must move through their full range of motion. Only a perfect change from muscle contraction to muscle relaxation will secure what we call perfect relaxation and not overrelaxation. It is of special importance that the chief muscle of respiration, the diaphragm, operates according to its anatomic structure. As compared with the diaphragm we would like to consider all the other muscles—namely, the intercostals, back muscles, etc.—as auxiliary muscles. This term should be applied to these muscle groups and not to the trapezius, sternocleidomastoid, scalenus, and the other muscle groups that usually are given this name because they work feverishly in a dyspneic condition. The diaphragm should set the rhythm for respiration, and the other muscle groups should follow its lead. In case the so-called auxiliary muscle activity should prevail, we will note what we consider distorted respiration. This type of breathing we frequently find described in textbooks as thoracic, costal, or abdominal breathing, constituting three separate ways of breathing. It has previously been thought possible for these different methods of respiration to exist simultaneously, and they also have been thought to have antagonistic effects. Thoracic breathing was supposed to be a typical female peculiarity, and abdominal breathing was considered to be typically masculine. These so-called different breathing types were applied individually for therapeutic and educational purposes (talking, singing). This teaching must cause an overdevelopment of a certain part of the auxiliary muscle groups at the expense of another part and the consequence is a restriction of diaphragm function, which in turn will cause a hypertensive state in other muscle groups as described above. It should be stated that for the same reason an overrelaxed condition may be produced, as typified by the so-called "débutante slouch."

In both cases re-education of the respiration and development of normalized breathing will remedy these conditions. Overrelaxation will be discussed at some later opportunity.

Let us here consider the consequences of shallow breathing.

1. There are individuals, probably the majority of all human beings, who constitute

PULMONARY EMBOLISM—DIAGNOSIS

JULIAN M. FRESTON, M D , New York City

THE purpose of this paper is to present 5 cases of pulmonary embolism which occurred on the Medical Service of Roosevelt Hospital within one year. Four of these cases were confirmed by autopsy. The fifth recovered. In only 1 case was a clinical diagnosis made.

An effort will be made to establish criteria by which the diagnosis of pulmonary embolism may be made with greater certainty and to call attention to other cardiorespiratory conditions with which pulmonary embolism may be confused.

Pulmonary embolism as a cause of death is undeniably important. Belt,¹ reporting on 1,990 consecutive autopsies, had found that 136 patients died with pulmonary emboli. Barnes² reported from the Mayo Clinic that pulmonary embolization accounted for 6 per cent of the postoperative deaths. I think most of us tend to consider pulmonary embolus as being particularly a postoperative accident. However, studies show that the cases are about equally divided between medical and surgical types.

The occurrence within a year of these cases in which there had been no antecedent operation has brought this problem forcibly to our attention. All of the fatal cases came to autopsy, where the association of thrombosis of the deep veins of the leg with pulmonary embolization was shown in each case.

On re-examination of the evidence it was found that certain features presented themselves at the time which would seem to have made diagnosis possible on clinical and laboratory grounds.

Certain diagnostic principles have been established by others on excellent experimental and pathologic evidence, and it is intended to use these in presenting our 5 cases in order to complete the clinical picture of pulmonary embolism. By so doing it is hoped that more accurate diagnosis of the condition may be made.

Of these 5 cases, 4 were between the ages of 50 and 55. The fifth was a Filipino of 37. One was a woman. Two had had symptoms referable to the cardiovascular system, 1 for two years and 1 for five years, auricular fibrillation was present on admission in the

latter case. The onset was sudden in 3 cases, less dramatic in the others. The chief complaint at onset was sharp axillary chest pain in 2, precordial burning pain with accompanying knifelike stabbing pain in 1, and substernal fullness in 1. Sharp abdominal pain occurred in 1. Dyspnea was present in all on or before admission. Faintness or actual fainting had occurred in 3. Pain in the lower extremities had occurred in 2, though in only 1 was it sufficiently localized to be of diagnostic aid. Hemoptysis occurred in 1, and mental symptoms during the course, in 2 of the patients.

The significance of mental symptoms, which consisted of confused and incoherent babbling in 1 of our patients and maniacal episodes in the other, should be recognized, for these symptoms and their variants are apt to lead one astray diagnostically.

The physical findings on admission included dyspnea, tachycardia, fever, leukocytosis, and cyanosis in all and polycythemia in 1. Signs such as dullness or rales were present in the chests of 3, and fluid was present in 2 of these. The blood pressure was depressed in 2 and could not be obtained in 1 whose symptoms came on an hour and a half before admission.

It is apparent that only 1 of these 5 patients was seen during the period of acute collapse, and in this patient the discovery of a tender popliteal mass led to the correct diagnosis. In the other patients shock or evidence of phlebotrombosis were absent and a clinical diagnosis was not made.

In the following case reports it is of importance to note that pulmonary embolism usually occurs as a series of emboli. The disease is one of multiple episodes. Single, suddenly fatal embolizations do occur, but in our 5 cases the duration of hospitalization was from one to three weeks and of antecedent symptoms from one and a half hours to three weeks. This feature of recurrent embolization gives us an opportunity to attempt therapy. Regarding therapy, the use of heparin for its effect on blood coagulation will probably occupy an important position. Chemotherapy when the original venous thrombosis can be assumed to be infectious—which it often is not—is probably a useful adjuvant. However, evaluation of therapy will depend

Discussion

Dr Joseph A. E. Syracuse, *Buffalo, New York*—Dr Behrend and Dr Weiss have again contributed a manuscript that obviously reflects the results of their careful study, their keen observations, and their logical conclusions. One cannot help but agree with them that the subject is not new, but surely their mode of presentation and method of explanation is to be commended, for, after all, the subject is not one that engages our interest and curiosity as one that is entirely new.

"Therapeutic relaxation" sounds simple enough, but its implications are multifarious. If you have read or, may I say, read and reread, Jacobson's profound description of his technic in *Progressive Relaxation*, you will little wonder why Drs Behrend and Weiss turned to a simpler and more practical method of securing therapeutic relaxation. Jacobson may have excellent results under his own personal guidance and instruction. The average physician will understand and interpret such terms as "general," "local," and "differential relaxation." And we may also comprehend such terms as "residual tension," "the cultivation of muscle sense," "diminishing tension," "tensions and strains," and "moving and static tension"—but will he succeed in transmitting his wishes to the average patient? Will he succeed in receiving the desired response? As Drs Behrend and Weiss state, his method "is difficult to teach and it demands long and exacting cooperation of the physician and patient" and, also, "introduces

the factor of mental activity." I am afraid that the average patient we see in our office is not, as yet, quite prepared to cooperate in receiving that caliber of therapy.

The simpler method, as just read to us, is based on "accomplishing relaxation by influencing the respiratory system." I am glad to note in their explanation recognition of the potential formation of a vicious cycle, to recapitulate (1) shallow or incorrect breathing, (2) respiratory muscle tension, (3) circulatory disturbance (alteration of the carbon dioxide balance), (4) sympathetic nervous system irritability, (5) muscle group tension, (6) residual tension, (7) reflex transmission of residual tension to muscle groups, (8) postural changes. All of which brings us back to shallow or incorrect breathing, respiratory muscle tension, etc.

The sequelae of this cycle are many, as has been enumerated. We all know how many times worried and weary mothers bring to our offices youths whose posture is such that they are sure that "Johnnie" has "tuberculosis," "rheumatism," "is developing a hunch back," "has a dislocated shoulder," "is knock-kneed," "has fallen arches," is "lazy," or "has sleeping sickness," etc., all of which can easily be corrected by proper guidance in corrective exercises, especially that of breathing.

I for one shall employ this technic of Drs Behrend and Weiss whenever indicated. It may be the answer to several puzzling problems in the past.

I should like to congratulate the authors on their most illuminating and delightful paper and wish to express my sincere thanks in having been extended the opportunity to discuss—or should I say endorse—their presentation.

HEALTH IN ARMY CAMPS

"Excellent medical care" is the finding, in three words, of the Medical Society of the State of New York, following a survey of New York State army posts and camps.

Of interest to veterans of the World War is the news that "light duty" is out. A man is either sick or well, but is no longer marked for light duty. It is a welcome change, for many a man in world war camps suffering from "flu" or a heavy cold was forced to work about his barracks.

The survey is a constructive service to the people of the state, many of whom have boys in camps. Carried out with the full cooperation of military authorities, it was made impartially by experts, assuring a sound and experienced report.

It gives full assurance that the health and welfare of the men in service are receiving the best kind of attention.

—Syracuse Post Standard,
Aug 3, 1941

BARGAIN DAY IN THE NEXT WORLD

A few weeks ago an artist was employed to renovate and retouch some oil paintings in an old church, and when he sent in his bill for \$26 87 he was told that an itemized bill was desired.

He accordingly submitted the following

For renewing Heaven and adjusting the stars	\$ 7 12
For touching up Purgatory and restoring the lost souls	3 06
For brightening up the flames of Hell, putting a new tail on the Devil and doing odd jobs for the damned	7 17
For putting a new stone in David's sling and arranging Goliath's head	6 13
For mending shirt of Prodigal Son	3 39
	\$26 87

—Journal of Allergy

The patient was an obese, dehydrated woman with blue mottling over her chest and extremities. Her heart was rapid but otherwise not noticeably abnormal. Her lungs were clear and there was slight tenderness over the right upper quadrant. There was slight pretibial edema. The admission diagnosis included questionable glomerulonephritis, questionable impending uremia, and questionable gallbladder disease. The urea nitrogen determinations during her hospital stay were 25, 86, and 105 mg per hundred cubic centimeters.

The respiratory rate increased steadily, and a terminal tachycardia occurred. The patient died on May 6. The electrocardiogram, which was considered to represent atypical posterior wall infarct, included all the features necessary to make a diagnosis of pulmonary embolism. The most prominent symptomatic feature was abdominal pain for which no cause could be found either during life or later at autopsy.

Case 5—A. C., a man aged 37, was admitted on June 17 complaining of shortness of breath for three weeks and fainting spells for two weeks. For three years the patient had had migrating pains in the ankles, knees, and hips. These joints swelled up one at a time and became tender and painful. He had also had burning precordial pain with occasional knife-like pains that did not radiate. Three weeks before, while at rest, he became short of breath. During the past two weeks he had become dizzy and on several occasions fainted when he tried to get out of bed. His left leg became swollen, and both feet felt continually cold. He was conscious of palpitation, and precordial pain was constant. He had been orthopneic for the past two weeks.

On admission the patient was cyanotic and breathing rapidly. The pulse was 150, but no definite cardiac abnormality could be made out. There was slight dullness in the right axilla. The diagnosis on admission was right lower lobar pneumonia because dullness and harsh breathing were found at the right base. Fleeting signs consisting of dullness and a few rales were heard from time to time on both sides of the chest. However, dyspnea was the most prominent feature throughout, and the patient died suddenly on June 22. The electrocardiogram showed the typical changes associated with acute cor pulmonale, and the chest x-ray demonstrated a prominent conus.

These cases were reviewed and an effort was made to see if laboratory evidence could be used to supplement the clinical findings and thus permit us to arrive at a correct diagnosis.

In 1935 McGinn and White,² and shortly afterward Barnes³ of the Mayo Clinic, published their independent observations on electrocardiographic findings which they considered diagnostic of pulmonary embolism.

FIG 1 Reproduction after Barnes showing diagrammatically electrocardiographic changes found in pulmonary embolism. Note lead IV reversed from lead IV F used in accompanying illustrations.

The following is a list of the changes described by these authors

- 1 Prominent S₁
- 2 Low origin of the T in lead I
- 3 Staircase ascent of ST in lead II
- 4 Inversion or flattening of T₂ without elevation of ST₂
- 5 Presence of Q₃
- 6 Inversion of T₃
- 7 Inversion of T₄

Fig 1, taken from Barnes,⁴ represents in diagrammatic form the typical electrocardiographic changes—note that old lead IV is reversed from lead IV F, now more commonly used. Figs 2, 3, and 4 represent serial changes in 1 patient occurring over a period of fifteen days.

on accurate diagnosis of the original condition and will develop most rapidly in those clinics where accurate diagnosis of embolization is stressed

Case Reports

Case 1—K P., a man aged 51, was admitted on August 5 with a complaint of substernal fullness and a feeling of faintness of one and a half hours' duration. These sensations had come on while the patient was at rest and had increased progressively until he was brought to the hospital. Two days before admission he had developed a pain in the left leg between the knee and ankle and had noticed a tender lump in the popliteal space.

On admission the patient was pale and apprehensive, with ashen lips and rapid, shallow breathing. Heart sounds were distant and the rate was 120. His blood pressure could not be obtained. His lungs were clear. There was slight swelling of the left leg and a palpable mass in the popliteal space. The admission diagnosis was thrombophlebitis of the left popliteal vein and pulmonary embolism with question of coronary occlusion. In the hospital he had several more attacks, consisting of shortness of breath and coughing. After one particularly severe episode there was chest pain, and a friction rub was heard over the left lower lung field. One morning, three weeks after admission, while shaving in bed the patient became ashen gray and expired immediately.

The diagnosis in this case was made on the presence of thrombophlebitis, changing lung signs, and dyspnea. In addition, the electrocardiogram on one of three examinations and the chest x-ray studies were diagnostic.

Case 2—R A., a man aged 51, was admitted on February 12 with a chief complaint of pain in the right side of the chest for two weeks and in the left side of the chest for three days. Two weeks before admission he had developed an aching and stabbing pain in the right axillary region which was constant and was accentuated by deep breathing and coughing. Ten days later this pain disappeared but was followed by the same sort of pain in the left side of the chest in the axillary line. In the past three days there had been coughing with hemoptysis. He was dyspneic "because of pain on deep breathing."

The patient appeared feverish and exhausted. His pulse was 100 and his blood pressure was 120/80. His heart was normal, and on the right side of his chest there was dullness to flatness at the right base posteriorly and in the axilla. Egophony and fine rales were present over the right base.

The diagnosis on admission was right lower lobar pneumonia, right pleural fluid, and early left lower pneumonia. Long chain streptococci were found in the sputum but no pneumococci. Later cultures from the sputum showed *Streptococcus hemolyticus* and *Staphylococcus aur-*

eus. No growth was obtained from the chest fluid. There was no evidence of tuberculosis in an injected guinea pig. Three weeks after admission he complained of pain in the right calf, which lasted two days and was diagnosed as thrombophlebitis. The connection between this and the pulmonary signs was not then appreciated. After a febrile course with multiple thoracentesis and gradual improvement in the pulmonary signs, the patient was able to leave the hospital on April 13.

Diagnosis could have been based on the thrombophlebitis, the variation in lung signs, and sterile effusion. Confirmation is based on x-ray findings, particularly evidence of linear scarring.

Case 3—P H., a man aged 58, was admitted on May 7 complaining of dyspnea for seven days and pain in the left side of the chest for from four to five days. There had been dyspnea on exertion for from four to five years, but one week before admission this had been increased. Four or five days before admission he had noticed gradually increasing pain in the left costal margin, which was increased on movement and exertion. He had been orthopneic for two nights and had noticed edema of the ankles for one day.

The patient was cyanotic and orthopneic. His heart was markedly enlarged to the left, rapid, and totally irregular. There was splinting of the left side of the chest with signs of fluid at the left base and moist rales at both bases and in both axillae. There was pitting edema of both legs and ankles. Admission diagnosis was auricular fibrillation and hypertensive heart disease with congestive failure, coronary thrombosis was to be ruled out. Left thoracentesis was performed, and 1,100 cc of fluid was obtained on the day after admission. The patient's course was febrile, and there were several hallucinatory and almost manic episodes. Dyspnea was prominent throughout the course, and the patient died on May 16.

Diagnosis would have been difficult. The bilateral venous thrombosis produced edema, which was explained on the basis of cardiac failure. Pulmonary findings and x-rays were confused by pulmonary congestion, and the electrocardiogram was not diagnostic. However, the episodic nature of the course should have suggested the correct diagnosis.

Case 4—T G., a woman aged 55, was admitted on April 25 with a complaint of sharp lower abdominal pain for three days. The patient had been known to have high blood pressure for two years and had been dyspneic when climbing stairs for one year. Five days before admission, while brushing teeth, she had fainted and had had a profuse watery bowel movement. She fainted again when she tried to walk. The patient had an insatiable thirst all that day and the next and had been noticeably weak and irritable since the onset. For the past three days she had intermittent severe lower abdominal pain, which was worse on coughing.

3 The triangular-shaped shadow if it occurs—as at the lower lung borders—has its apex distal rather than central

4 Long axis of an infarct is parallel to the longest pleural surface involved

5 The proximal border of an infarcted area is convex

6 Multiple areas of infarction are frequently superimposed, producing shadows that are round or irregular, which makes interpretation difficult

7 Fluoroscopic or oblique x-ray examination will demonstrate aeration between the multiple shadows and the contact of each with the pleura

In addition, the hilus shadows on the affected side are usually accentuated, and the diaphragm is frequently elevated. Again, confusion is produced by the presence of fluid and of pulmonary congestion, either of which masks the x-ray findings. Figs 5 and 6 represent serial x-ray changes in 1 case. Healing results in linear scarring visible by x-ray and considered diagnostic by the above authors.

We must recognize that pulmonary embolization with or without infarction is a fairly common medical condition, often unrecognized when the primary venous thrombosis is not obvious. Recognition of the venous thrombosis is often extremely difficult. In this connection it is of interest to note that thrombosis of the popliteal veins—unilateral in 3 cases, bilateral in 1—was found at autopsy in all of the fatal cases. Edema was either absent, slight, or considered to be due to the primary cardiac condition. Diagnosis can more frequently be made if the condition is considered, particularly in persons over the age of 50.

It is realized that x-ray interpretation of films that must, of necessity, be made at the bedside is difficult. It is also important to remember that the electrocardiographic changes may be fleeting, and serial examinations are often necessary. However, properly used in conjunction with the clinical findings, these aids can be useful diagnostic adjuncts.

Summary

1 Five cases of pulmonary embolus which occurred within one year on the medical service have been presented

2 Four of the cases were fatal, and the diagnosis was confirmed by autopsy in all

3 In all of the fatal cases thrombosis of one or both of the popliteal veins was found at autopsy

4 Electrocardiographic changes diagnos-

FIG 5 R. A. X-ray of chest shortly after admission showing marked changes in lower right lung and obliteration of left costophrenic sinus

FIG 6 R. A. X-ray taken five weeks later showing several areas of increased density in the right lung probably indicating multiple areas of infarction. Note there is clearing of the left costophrenic sinus suggesting that infarction in that area was incomplete

tic of pulmonary embolism were present in 3 of the cases

5 X-ray changes helpful in making the diagnosis of pulmonary embolus were reviewed

6 An attempt was made to correlate clinical and laboratory findings that might lead to more accurate diagnosis of pulmonary embolus

FIG 4.

FIG 2 K P Electrocardiogram taken on day of admission showing none of the diagnostic changes

FIG 3 K P Electrocardiogram taken three days later showing all diagnostic changes

FIG 4. K. P Electrocardiogram taken sixteen days after admission showing no change except left axis deviation

Two of the patients had single electrocardiograms that were not diagnostic. It is important to appreciate that the presence of characteristic electrocardiographic changes depends on the production of cor pulmonale—that is, on metabolic changes in the right and possibly the left ventricle. It is possible that, if clinical collapse does not occur, the electrocardiogram will remain within normal limits. It must also be remembered that these changes may be temporary. On the other hand, conditions that produce right ventricular strain, mitral disease, pulmonary emphysema, etc., also produce similar electrocardiographic changes and must be ruled out on clinical or other grounds.

It is probable that the shifting character of the electrocardiogram is the most significant diagnostic feature. In any case, the limitation of the electrocardiogram must be recognized and given due consideration.

The x-ray diagnosis of pulmonary infarction also presents its problems. Jellen⁵ in his article and Castleman and Hampton⁶ in another study present us with some useful concepts and diagnostic criteria. A list of these follows.

1. Infarcted areas are always in contact with one or more pleural surfaces, usually at junction of two surfaces.

2. The shape of the infarct is dependent on the shape of the area of lung involved.

POPULAR EDUCATION AS A FACTOR IN THE SOLUTION OF THE CANCER PROBLEM

JOHN M. SWAN, M D , F A C P , Rochester, New York

IN 1926 the American Society for the Control of Cancer invited representative students of the cancer problem from the United States and Europe to attend an International Symposium on Cancer at Lake Mohonk in September. This conference was attended by 109 delegates.

The European delegates came from Belgium, England, France, Germany, Holland, Italy, and Switzerland. From this side of the ocean delegates from Canada were present in addition to those from the United States.

At the conclusion of the four-day meeting a resolution was passed which "expressed the unanimous opinion of the Symposium upon a list of practical facts and sound working opinions which should serve as the basis of the campaign which mankind should make against cancer." This resolution contained the following paragraphs:

"3 The control of cancer, so far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which depends upon the intelligent cooperation of the patient and the physician.

"4 Persons who have cancer must apply to competent physicians at a sufficiently early stage in the disease in order to have a fair chance of cure. This applies to all forms of cancer. In some forms early treatment affords the only possibility of cure."

"7 The public must be taught the earliest danger signals of cancer which can be recognized by persons without a special knowledge of the subject, and induced to seek competent medical attention when any of these indications are believed to be present."

"14. Emphasis should be placed upon the value of the dissemination of the definite, useful, and practical knowledge about cancer, and this knowledge should not be confused nor hidden by what is merely theoretical and experimental.

"15 Efforts toward the control of cancer should be made in two principal directions:

(1) The promotion of research in order to increase the existing knowledge of the subject, and (2) the practical employment of the information which is at hand. With our present knowledge many lives could be saved which are sacrificed by unnecessary delay."

Answer to the Criticisms of a Program of Popular Education

Based upon these principles the New York State Committee of the American Society for the Control of Cancer, which was formed in 1921, inaugurated a state-wide educational program, directed primarily to the laity. During the development of this program, the Committee discovered certain objections on the part of some members of the medical profession who maintained that, as we do not know the cause of cancer, we cannot control it, that we have no cure for cancer and, until we do have a cure, cancer cannot be controlled, that a discussion of cancer to groups of lay people will produce "cancerphobia", and that a program of public education is attended with the danger that "ballyhoo" methods will be an unescapable result.

Concerning the first criticism, it may be said that, from the point of view of the attack on the problem, we know enough of the cause of cancer to develop a program of control. We know that cancer follows the prolonged action of carcinogenic agents upon the tissues. These carcinogenic agents may be physical, such as prolonged exposure to strong sunlight, or the emanations from radium or roentgen rays, mechanical, such as the irritation of the sharp edges of cavities in necrotic teeth, chemical, such as tar, dibenzanthracene and decomposed retained secretions, the products of the growth of bacteria of low virulence, and thermal.

Concerning the second criticism, it was maintained that yellow fever and malaria were controlled when the cause was discovered. However, it must be realized that cancer is not a transmissible disease like malaria and yellow fever. That cinchona bark was used by the Peruvian Indians as a cure for malaria and was introduced into Europe in 1640, while Laveran did not discover the *Plasmodium malariae* until 1880. Furthermore, the method of transmission of yellow fever by the

NEW PORTABLE TRANSFUSION KIT ANNOUNCED

A new portable emergency dried plasma transfusion kit that can be set up and used at or near the site where the injury occurs, is described in the *Journal of the American Medical Association* for June 21 by Dr John R. Upton, B E Emery, M S, and R. B. Clark, San Francisco

"In these grim days," the authors say, "the need for some foolproof dependable transfusion outfit which can be set up by any doctor or well-trained nurse and utilized at or near the site where the injury occurs is of tremendous importance. Army, navy, air force, and even civilian casualties now can be treated immediately by drawing on supplies in strategically placed depots. Experience in the present war has already shown the urgent need for plasma transfusion in shock, burns, and hemorrhage. If transfusion is delayed, inevitable and irreversible changes occur in a large proportion of cases."

The kit contains the residue from 250 cc of liquid plasma, which, on reconstruction with sterile water, would be equivalent to 250 cc of "wet" plasma or 500 cc of whole blood. The dry plasma is contained in a 500-cc vaccine sleeve type rubber stoppered bottle which is hermetically sealed in a snug-fitting tin can. Cotton wool is tamped snugly about the base and neck. The tin can is 3 1/4 inches in diameter and 8 inches tall.

There is a 500-cc calibrated dispenser bottle of sterile water which is fitted with the new type sterile cap that ensures sterility after bottling and prevents contamination during administration. The authors explain that the sterile water is contained in the kit because of the fact that water is extremely difficult to sterilize and equally hard to keep sterile.

Also contained in the kit are an intravenous needle, a rubber tubing of Y design, a mechanical filter, and drip chamber, and a needle attached to the other short arm of the Y tube. This is packed in a sterile manner with the needles being protected by inclosure in a test tube. This segment is united, sterile, and ready to use. There also is contained in the kit a spinal type needle with stylet in a sterile test tube.

Explaining the method of administration, the authors say "The corrugated cardboard container is slit open with a knife along the designated line. The contents are removed and, if no table is available, the cardboard box can be up-ended and used for a table. Any improvised stand can be used to suspend the bottles, on board ship or in a hospital ward these are always available. If no such stand is available because of an exposed position, use can be made of a sapling, a tent stake, or even a gunstock with

the bayonet stuck firmly into the ground. The rate of flow can be accurately gaged by the turn-screw pet cock, so that the height of the object used to suspend the bottles plays little role except for support. The tin can is carefully opened by the usual type of can opener, but care is needed to make sure the can is opened at the designated end to avoid damage to the glass bottle."

When the patient has been made ready for the transfusion the needle attached to the short arm of the Y tube is inserted just through the stopper into the powder plasma flask and the glass nozzle at the other end of the Y tube is inserted through a designated hole in the rubber cap of the sterile water bottle. The spinal type needle is then inserted alongside the needle already piercing the rubber stopper of the dry plasma flask. This needle is to break the vacuum in the bottle during the reconstruction process. The tube running into the recipient's needle is clamped off with the screwcock and the bottle containing the sterile water is up-ended so that its contents flow into the bottle containing the dry plasma. The dry plasma or serum will dissolve in a few seconds. When the plasma is completely dissolved both bottles are up-ended and some water is allowed to run through the tubing, and the air bubbles therein are eliminated by raising and lowering both bottles several times. The apparatus is then ready for the transfusion.

Discussing the kit the three men say "It will adequately meet conditions imposed on it by modern warfare. It will fill a long-standing need in civilian life and practice, smaller hospitals, emergency stations, fire houses, industrial factories, oil refineries, and forestry outposts should keep such a kit or kits in their emergency lockers. Armed forces ashore and afloat will require large numbers of these or similar kits. They will enable transfusion therapy to be moved to more advanced positions in actual warfare, smaller vessels will have transfusion facilities for their wounded. Gun flash, explosion, and incendiary bomb burns will now be treated in the first critical hours.

"The financial cost of these kits is small when the lifesaving properties are considered. The federal government may find it advisable to produce and dispense such units. Our civilian population must realize that its part in the national preparedness program will be to supply blood voluntarily for national defense needs, thus at the least it can do to pay for its protection. Such a widespread program would guarantee a constant and adequate supply of dried blood plasma."

MATERIAL FOR MEDICAL WAR HISTORY

Southwestern Medicine invites physicians of the southwest who enter military service to write

letters telling of their impressions and experiences for publication in its pages.

We should point out the fact that complete destruction of the growth must be accomplished and that, in the present state of our knowledge, surgery and irradiation with radium, x-rays, or a combination of these agents are the only reliable methods for the accomplishment of the destruction.

We should attempt to disabuse the minds of the laity of the erroneous popular notions concerning cancer—such as statements that cancer is the result of eating tomatoes, drinking milk, eating pork, the use of aluminum cooking utensils, the employment of artificial refrigeration—and of the notion that cancer is a shameful disease, that it follows a single injury, and that it is transmissible. At the same time we should emphasize the fact that absence of pain is no criterion that cancer has not already begun.

Until the mechanism of the inheritance of the susceptibility to cancer in the individual exposed to the action of a carcinogenic agent is thoroughly understood, we should assure the laity that, in the human family at least, cancer is not directly inherited.

An attempt should be made to point out to the layman that he must present himself to a competent physician for examination when the symptoms mentioned above are noted. It is a personal problem, no one can act for the individual.

One of the first objectives in a cancer educational program, after the elimination of the fear of hearing the matter discussed, should be to show the layman indisputable evidence that cancer can be diagnosed and properly treated in his own community. To that end, we have carried on in Rochester for the past eight years an investigation designed to show that there are patients who have had cancer, who have been adequately treated in the hospitals in the city, and who have survived without recurrence for five years or longer.²

We have a record of 298 cases of five-year survivals, 73 of which are ten-year, eleven-year, and twelve-year survivals. In the latter group there are 4 cases of gastric adenocarcinoma. In every one of these cases the histologic slides have been reviewed by three competent pathologists, and all have concurred in the original diagnosis. If we had included the cases of basal-cell carcinoma of the skin treated by the dermatologists, in which no histologic slide was available for review, and if we had included cases in which two of the pathologists agreed to one who disagreed with the histologic diagnosis, our list could have been much larger.

The Concurrent Educational Program Directed Toward the Medical Student and the General Practitioner

On the other hand, there is a definite necessity for the training of physicians to look with suspicion upon those symptoms that indicate the presence of pathologic processes that may become cancer. In too many instances the delay in insisting upon biopsy and the use of temporizing methods of treatment are discovered in the study of the anamnesis of individual cases of cancer.

Cramer^{1b} says "Perhaps the greatest difficulty (in the solution of the cancer problem in man) is the unjustifiable pessimism which pervades the medical profession concerning cancer. We are still being told by distinguished clinicians that cancer is a mystery, that we know nothing about cancer, and that we must wait until the cause of cancer is found—whatever that may mean—when the cure for cancer will automatically follow, which is by no means true."

Opinions of Authors of Papers Appearing in the Medical Periodical Press

Hartman,¹⁰ discussing the treatment of cancer of the rectum, advocated the education of the public and the physician. He said that the surgeon ought not to have patients referred to him who have been treated medically for "months and months" without having had a local examination which is "so simple, so useful, and so often neglected."

Bloodgood,² a pioneer in the advocacy of the education of laymen, says that the value of the education of the public and of the profession in the importance of early and accurate diagnosis, skillful surgery, and accurate radiotherapy is well known.

Spies¹⁹ is of the opinion that cancer education has increased the number of people who present themselves to physicians for benign lesions and early new growths.

Guggisberg,¹ in discussing cancer of the uterus, says that the practicing physician can do much to secure early examination and early diagnosis. Often the influence of one woman upon another is of great value in securing prompt pelvic examination.

Cramer^{1a} says that the only method available at present to reduce cancer mortality is the educational program for early diagnosis.

As a result of the anticancer campaign in Sweden, Forsell⁶ says "It is wise to leave the matter of anticancer education to the various anticancer societies which wish to help in

mosquito was worked out in 1898-1899, while Noguchi did not isolate the *Leptospira icteroides* until 1918, and that today the causative relation of that organism to yellow fever has been discarded by the research scholars, and yellow fever is believed to be a virus disease.

The critics also pointed out that tuberculosis was controlled when the cause of tuberculosis was discovered. However, the *Bacillus tuberculosis* was isolated in 1882 by Koch, but it was not until 1903 that the present method of tuberculosis prevention was developed by Trudeau and his pupils.

Again, vaccinia will control smallpox and we do not yet know the cause of either, unless they also prove to be virus diseases.

In relation to the criticism that we have no cure for cancer, it may be pointed out that the removal of a tumor from the female breast which proves, on microscopic examination, to be the result of a chronic cystic mastitis in which there is an area of cancerous change and if the removal is followed by the survival of the patient for five or ten years or more without recurrence, it would seem legitimate to claim that such a cancer had been cured. Furthermore, in patients who present lesions of the cervix of the uterus which prove, on microscopic study, to be examples of chronic cystic cervicitis or other low-grade inflammatory change of the tissues of the cervix and in which, after suitable treatment, subsequent examinations show an absence of the development of cancer, it seems legitimate to conclude that cancer may have been prevented.

In this connection the observations of Pemberton and Smith¹³ would indicate that cancer can be prevented. They reported follow-up studies of 3,814 patients in whom trachelorrhaphy had been done in only 5 of which cancer developed later, 1,408 patients in whom cervical cauterization had been done, none of whom developed cancer, and 740 patients in whom cervical amputation had been done, none of whom developed cancer. On the other hand, in 669 cases of cancer of the cervix only 12 had had trachelorrhaphy and none had had either cervical cauterization or amputation of the cervix. Later, Bartlett and Smith¹ reported a follow-up study of 1,700 patients in whom cervical cauterization had been done with no subsequent development of cancer.

Concerning the third criticism, it is our experience that an educational program does not produce fear. The fear already exists. Discussing the question brings it to the surface, so that frequently it can be dispelled by

reassuring the patient who is able to control his emotions.

Meigs¹² says that it is of extreme importance that women be induced to accept treatment when there is some hope of cure. This can be accomplished best through educational methods, appealing both to the laity and to the medical profession. Cancerphobia often results, but the good that the education does far surpasses its harm.

The only answer to the criticism that "ballyhoo" methods will be adopted is that so long as an educational program is controlled by physicians such methods are not likely to be adopted. Once the program is under the control of laymen, no matter how well intentioned they may be, there is real danger that inaccurate and extravagant statements may be made and that the objects of the program may be nullified thereby.

The Matters to Be Discussed at Meetings of Lay People

We should be ready to tell laymen and laywomen that chronic sores that do not heal readily, particularly if they are situated about the body orifices, that tumors, particularly breast tumors, that pathologic discharges from the hollow viscera, particularly if they are bloodstained, that disturbances of digestion occurring without demonstrable cause in persons in late middle life and early old age, and that melanomas, situated where they can be irritated by the clothing, are the symptoms that may point to the beginning of cancer. However, we should tell them that these symptoms do not mean that cancer has already developed but that they do indicate the existence of tissue changes in which cancer may develop. Furthermore, they should be told that these symptoms demand careful and well-planned study and that the lesions discovered should be suitably treated and cured.

We should be ready to explain to audiences of lay people, in language they can readily understand, that cancer is the result of the prolonged action of a carcinogenic agent on a definite tissue over an extended period, occupying a considerable fraction of the normal span of life characteristic for the species (Cramer¹⁴). We should emphasize the fact that cancer can be cured if it is diagnosed before metastasis has begun and that, even though metastasis has commenced but has not passed beyond the regional lymph nodes, a cure may be obtained—at least the patient may survive long enough to die of trauma or of a disease that is not cancer.

New Orleans between 1932 and 1936 Of these, 256 were Negroes (53.22 per cent) Of the negro patients, 60.0 per cent presented regional lymph node metastases when first seen Of 224 cases in which the records were adequate, 118 were considered suitable for radical operation (52.67 per cent) "These facts are a challenge to the profession to continue their efforts to educate the public"

Cramer^{5b} is of the opinion that "cancer is, unfortunately, a sensational disease, but the prevention of cancer is unsensational work The physicians who prevent a hundred cases of cancer have less evidence to establish their success than the surgeons or radiologists who cure five, nor will they get for their achievement any credit or financial reward The results of prophylactic work will become evident only after many years by a careful analysis of the national mortality statistics We need an educational program among medical men to establish in their minds the conviction that cancer is largely preventable and that every effort should be made to prevent it"

In his discussion of the cancer problem MacCarty¹² quotes Lounsbury who said "The longer I teach the more I am impressed with the infinite capacity of the human mind to resist the introduction of knowledge"

BLOOD PLASMA FROM CASEIN?

The possibility of using casein, a common ingredient of milk, as a means of building up the blood plasma of persons weakened by wounds, operative shock, or malnutrition has emerged from experiments at the University of Rochester

The studies were reported by a group of seven scientists including Dr George H Whipple, dean of the university's school of medicine The experiments were conducted on dogs, just as were those done in past years by Dr Whipple which led to a cure of pernicious anemia in humans and brought him a share of the Nobel Prize in physiology and medicine in 1934

Dr Whipple's collaborators in the present study were Dr S C Madden, L J Zeldis, Dr A D Hengerer, Dr L L Miller, A P Rowe, and A P Turner

A report in the *Journal of Experimental Medicine*, as quoted in the *New York Times*, describes the work Dogs were kept healthy for many weeks and in some instances gained weight, even though their diet was kept low in proteins and precious plasma proteins were repeatedly drained from their blood This was made possible by injecting into their veins a digest of casein, the milk protein The Whipple group concluded that the animals were able quickly to convert the casein digest into blood plasma

Casein is a cheap and common ingredient of milk, found in concentrated form in cottage cheese A white powder, it is commercially used as a carrier for pigments in paint, as sizing in making smooth paper, for glues, adhesives, and pastes Highly purified forms are used by scientific laboratories in animal feeding tests For introduction into the blood in the Rochester experiments, the pure casein was predigested with papain, an extract of tropical fruit, papaya

Although cautious in applying their finding to the question of aiding the war wounded and operative cases, the Rochester experimenters called the attention of the medical world to the advantages of casein digest, in cheapness and ease of handling over the use of stored human plasma

"Perhaps it is not for us to debate clinical problems," they said, "but we may mildly suggest that the experiments designed to study plasma protein production do have a bearing on the many-sided problem of shock as well as clinical hypoproteinemia (lack of proteins in the blood)"

If the body can be aided in producing new plasma proteins, this procedure may be as valuable as the administration of plasma by vein."

combating the disease. The official organizations for social work, the insurance companies, and the societies for sick benefits should find a special mission here. Informing the public about cancer without provoking an exaggerated fear is a task in the anticancer campaign which is as delicate as it is important. However, a number of physicians who have had experience with this subject are of the opinion that the thorough instruction of all physicians, as well as all those persons occupied with the care of patients, such as dentists, nurses, and midwives, concerning the early symptoms of cancer, is of more importance than the direct education of the public."

Ward²¹ says that early diagnosis is the most important single factor in the fight against malignant disease. "It seems to me, however, that, despite a natural aversion to airing medical subjects in the lay press, it should be possible to give advice without frightening people to death or offending the public taste."

MacCarty¹² points out that the cancer problem has five distinct parts, which he enumerates in the "probable order of practical importance." He puts the recognition or diagnosis by laymen, the general practitioner, the general pathologist, the surgical pathologist, the surgeon, and the teachers in medical schools in the first place. It is obvious that the education of the public and the education of the medical student and the medical practitioner must go hand in hand.

Smith¹⁸ says that it would seem that cancer education ("anticancer propaganda") for the lay public must be made much more effective if we are to expect patients to seek medical advice at an early date. On the other hand, this will be of no avail unless even more strenuous propaganda (education) is carried out within the medical profession in order to get the general practitioner to suspect cancer more frequently and to impress upon him the necessity for consultation upon points in which he hesitates to take the full responsibility for decision.

Greenough⁷ pointed out that in the Massachusetts General Hospital in Boston, in 1914, 26.0 per cent of the operable cases of cancer of the breast showed no involvement of the axillary lymph nodes. In 1926, 40.0 per cent of the cases of cancer of the breast showed no axillary lymph node metastasis. He was of the opinion that this is a clear indication of the value of popular education.

Handley⁹ advocates the instruction of men in the importance of personal hygiene because he believes that carelessness concerning sub-

preputial hygiene and cleanliness, while a menace to the male, is a more serious menace to the female.

Shore¹⁷ points out that in an unselected group of 744 patients with cancer admitted to St. Luke's Hospital in New York City only 182 or 24.4 per cent were operable. He says "Such a situation is deplorable and explains the small percentage (7.8 per cent) of five-year survivals. Education of the medical profession and of the laity is the only means of correcting such a condition."

Keynes¹¹ says the practitioner should teach the public that early cancer is painless and often curable. Whatever progress is made in surgical and radiologic technic, the end results will not improve unless more precise diagnosis can be made earlier and unless patients come more readily to seek advice.

Novak¹⁴ says that for the present the obvious point of attack in the cancer campaign lies in the effort to increase the proportion of cases in which treatment gives a chance for cure. The early cases, however, cannot be treated unless, on the one hand, patients are taught to ask for examination as soon as suspicious symptoms appear and, on the other hand, unless physicians look upon suspicious symptoms as requiring prompt and thorough study and unless they lose no time in making the necessary examination.

Physicians may help the cause of early diagnosis by taking part in an educational program directed to the laity, taking advantage of every opportunity to advise the individual patient of the necessity of heeding the danger signals and of developing in themselves habits of thoroughness and conscientiousness in the examination of patients who present the danger signals.

Ross,¹⁶ in discussing a paper by Balfour, pointed out the fact that the results of the treatment of gastric carcinoma are better in urban than in rural communities. He says "More can be accomplished only if we can aid these agencies in the education of those people who are likely to develop cancer, or who have it and who know nothing about the disease. While the educational program of the American Society for the Control of Cancer, the American College of Surgeons, and other groups is reaching the patient in the medical centers, the people who live in rural communities—nearly one-half of the population of the United States—know nothing of the program or of the need of it."

Cohn⁴ has studied 481 cases of breast cancer admitted to the Charity Hospital in

in accordance with most observers' figures

Season

In 1925 Zahorsky² stated that most cases occurred in spring, summer, and early autumn, although in his original group he had no cases in the hot summer months. Heiman⁴ reports that most of his 30 cases occurred in late summer, early fall, and during the winter in batches. Ruh and Garvin⁵ saw the majority of their 60 cases in the late spring. The tendency for them to occur in groups has been noted, and this is true in our experience.

In the entire series the distribution of attacks according to months is as follows

	Number of Attacks	
January	0	
February	10	18 or 16% winter
March	8	
April	5	
May	12	28 or 25% spring
June	11	
July	13	
August	17	40 or 35% summer
September	10	
October	14	
November	6	27 or 24% fall
December	7	

Symptomatology

Certain aspects of the clinical picture may be discussed further

Fever is the outstanding symptom. The majority of patients have a peak temperature of 103 to 104 F, some may go over 105 F, and in 2 cases no history of fever could be obtained. In 108 cases where the duration of fever was known, the fever persisted for one day in 2 cases, two days in 4 cases, three days in 99 cases, and four days in 2 cases. In the report of 54 cases accurately observed by Barenberg and Greenspan⁶ in an infant's home, it was possible to take four hourly temperature readings in all cases. They found that the infants fell into two groups. In the first group the temperature was elevated from the beginning and came down by crisis in about seventy-two hours. In the second group the maximum temperature developed on the second day and fell gradually to normal by the fourth day. Zahorsky² describes morning remissions in many cases, and this is true in our experience. The temperature reaction seems labile and is almost specifically affected by acetyl salicylic acid.

Irritability is common and, in many cases, extreme, sometimes persisting for several days after the rash has appeared. Some infants, however, are remarkably free of any symptom of irritability.

Anorexia is likewise a variable symptom—

the majority of children eat, but less well than usual. An occasional child will go through the entire course of the disease without loss of appetite.

In the 3 cases occurring in older children, 2 complained of headache as did the 31-year-old woman described by Cutts.⁷ In this case, except for this symptom initially and the fever, she had practically no symptoms. This is in accordance with one of the most important diagnostic features—the high fever in an infant who does not appear ill.

Vomiting and diarrhea occur but are rarely severe or persistent. In a few cases there is some cough.

Occasionally, one sees what might be considered a fulminating case. In these the onset is abrupt, often ushered in by a convulsion, temperature of over 105 F, and rather marked prostration. In these children, meningitis may be suggested, and in several of the hospital cases lumbar puncture was done to rule out this possibility.

On physical examination the throat is often inflamed and the eardrums injected. In some children this inflammation is enough to suggest a hemolytic streptococcal infection, and sulfanilamide has been given. This drug does not alter the course of the disease.

Adenopathy is, in my experience, uncommon. However, in 1 infant, seen for the first time with an extremely intense rash, there was sufficient swelling of the posterior cervical and posterior auricular glands to suggest German measles.

The *exanthem* looks more like that of German measles than that appearing with any other condition. Barbiturate or sulfanilamide rashes are somewhat similar. It is macular, dark rose in color, and usually discrete, with individual lesions between 1 and 5 mm in diameter. The rash varies tremendously in intensity. In some cases only a few spots are visible and then only for a short period, while in others the lesions may become confluent in places. The back, chest, abdomen, shoulders, and buttocks are usually most intensely involved, although the forehead, the back of the neck, and the area behind the ears may be involved. It does go beyond the hairline in the scalp when marked elsewhere and may also involve the extremities. If one examines the lesions across the light, many of them seem slightly raised above the surface. In 1 case, referred to above, the rash lasted about four days, but in the majority of children it disappears within thirty-six hours, leaving no pigmentation and no desquamation.

ROSEOLA INFANTUM (EXANTHEM SUBITUM)

BURTIS B. BREESE, JR., M.D., Rochester, New York

ONE of the most common pediatric problems in the home is high unexplained fever in a young child. Because roseola infantum is such a common cause of unknown fever in the young and because many practicing physicians are not well acquainted with this clinical entity, this group of 111 cases is presented.

To John Zahorsky, of St. Louis, belongs the credit of first separating the disease from the other exanthemas. In 1910 he presented a group of 15 cases to the medical profession.¹ His original description of the disease has stood the test of time, and his observations have been repeatedly confirmed.

"The patient is almost always a child under 3 years of age who is suddenly taken sick with high fever. The physician is called and, on examination of the patient, finds nothing abnormal. The fever continues but nothing abnormal can be found on the second, third, and even the fourth day, when the fever drops by crisis and the child who has been drowsy or very irritable sits up and commences to play. Coincident with the drop in temperature a morbilliform rash appears on the face and neck and rapidly spreads over the body. The eruption disappears in twenty-four to forty-eight hours. There are no sequelae. No desquamation follows the disappearance of the rash.

"These are the striking and characteristic symptoms: a prodromal fever lasting from two to five days, disappearance of the general symptoms with the appearance of the rash, and a morbilliform eruption."

Frequency

In 1925 Zahorsky² stated that he had seen over 300 cases. Reports of 20, 30, or more cases seen in comparatively short periods of time are not uncommon.

From January 1, 1936, until the end of December, 1940, a period of five years, I have seen 100 attacks in 98 patients of what I considered definite roseola infantum.

During the past ten years at the Strong Memorial and Municipal Hospital 13 cases were discharged with the final diagnosis of roseola. All these cases were admitted with diagnoses at variance with discharge impres-

sion. Many other children with the condition were seen in the outpatient and emergency departments but not admitted. This simply indicates that, as a rule, these cases are not seen in any number in hospital practice but are seen most frequently in private practice. As compared with the other exanthemas of childhood in my personal experience, roseola is the most common. This is true probably because of the high percentage of infants seen in pediatric practice.

In order to arrive at a rough estimation of the frequency of the disease in the population, 70 cases of infants who had been followed carefully through the first year of life were selected. In each of these children, I am relatively certain, no illness occurred in the first 12 months of life which I did not observe.

Of these 70 cases, 11 infants had definite roseola infantum within the first 12 months of life—approximately 16 per cent. According to my figures on age distribution of the disease, about 50 per cent (47) of the cases occur under the age of 1 year. If this is so, out of the original group we should expect 11 more cases, or a total of approximately 30 per cent, to have roseola eventually.

Age

Everyone who has written on this subject has stated that the disease is primarily one of infancy. Zahorsky² states that the youngest patient he has seen with the disease was 2 weeks old,* in my experience the youngest patients were 3 months old.

It is the fixed idea that this illness is one of infancy only, which may occasionally lead us astray in diagnosis. Morgan Cutts³ reports a case in a 31-year-old woman. Zahorsky² mentions several older children in his series. I have seen 2 eight-year-old children and 1 9-year-old child with the disease. However, about 47 per cent do occur under 1 year, 82 per cent under 2, and 93 per cent under 3. The greatest number of cases occurred in the tenth month (12 or 13 per cent).

Sex

In this series the sex incidence was equal. There were 55 girls and 56 boys. This is

From the Department of Pediatrics, University of Rochester School of Medicine.

* In Zahorsky's latest discussion² 2 months is given as the age of the youngest patient seen.

TABLE 1—DISTRIBUTION OF 121 WHITE BLOOD COUNTS IN ROSEOLA INFANTUM

White Blood Count	Day of Disease						
	1	2	3**	4	5	6	7
2,000-2,999	0	1	2	0	0	0	0

* Rounded to nearest whole number

lowing day it was more intense. The mother stated that the rash was identical in appearance with that which she had had the year before.

Robert H., aged 10 months, developed a fever of 102 F in May, 1939. I examined him on the first day of the fever and found nothing to account for it. His white blood count was 4,200. On the third day of the illness his temperature came down to normal for the first time, and he developed a mild roseola rash on the fourth day.

In June, approximately one month later and three days after he had been vaccinated for smallpox, he developed a temperature of 103 F without physical findings. This fever lasted for three days and then came down, and he developed a rash similar to the first one. On the fourth day his white blood count was 6,000. Whether this was a vaccinal rash, appearing early, or a second attack of roseola is difficult to say.

Laboratory Findings

The only characteristic laboratory finding in this disease is a relative leukopenia and lymphocytosis reported first by Levy¹⁰ and Veeder and Hempelmann.¹¹ Faber and Dickey¹² and Barenberg and Greenspan⁶ have confirmed this observation. However, most

of these counts were made on the third day of the disease or later. In our series, seventy-two white blood counts were done on 61 patients and thirty-three differential counts on 30 patients, a number of them on the first and second days of the disease as follows:

Day of Blood Count	Total White Blood Count	Differential Blood Count
1	13	5
2	29	10
3	18	10
4	3	3
5	3	3
6	0	0
7	1	1
Total	72	33

In order to obtain a larger number of blood studies than those contained in any single series, these counts were combined with those reported previously by others.^{6, 7, 11, 12} In this manner a series of 130 white blood counts and ninety-one differential counts were obtained. These counts had been done from the first to the seventh day of the disease inclusive and are presented in Tables 1 and 2.

Although, to my knowledge, this is the first attempt to combine our information of these blood findings in roseola infantum, from the statistical standpoint the number of observa-

The typical skin manifestation usually appears shortly before or shortly after the temperature reaches normal. In many cases the rash so alarms the parents that they take the child to the physician when it appears and after the disease has run its course

Day of Disease on Which Rash Appeared	Number of Attacks	Cases	%
1	0	0	
2	2	1	8
3	7	6	3
4	79	70	5
5	18	18	0
6	0	0	
7	1	0	9
Unknown	5	4	5
	112	100	0

In 1 infant, a doctor's child, the rash was so faint that had there not been careful observation it probably would not have been noticed. This brings up the question of whether the disease may occur without any rash being manifest. I have had several cases that ran a course not unlike roseola with the typical blood picture, and yet these infants had, as far as could be determined, no rash. Barenberg and Greenspan⁶ describe 3 patients with the characteristic course and blood findings who did not have the rash. In 1 of twins, both of whom had the disease, no rash appeared. Therefore, it seems extremely probable that the disease may occur without the appearance of a rash.

Complications

All the children seen in the home or office were free of complications except 1 who had a concomitant otitis media. In the hospital series, 3 children did have otitis media at the same time or shortly thereafter. No other sequelae were noted. This is in agreement with the generally accepted opinion that complications do not occur with roseola infantum.

Communicability

The disease has been described as one that is only slightly, if at all, communicable. In our experience this would seem to be the case. However, on examination of our series we find that there were only 5 susceptible contacts and of these, 2 developed the disease.

Zahorsky mentions one family in which 2 children came down with the infection within three days of one another.⁷ Cushing⁸ described an epidemic of 6 cases occurring among 10 infants who were in an institution. The incubation period in these cases was ten days in 3 children, seven days in 1 case, and nine days in the remaining case. In Barenberg and Greenspan's series it was possible to trace the incubation period in 18 cases. The range was

from five to fifteen days with an average of ten days. The occurrence of the disease in twins, referred to above, is of interest because it shows (a) that the disease may occur without the rash and (b) that the incubation period is probably around five days. For this reason these cases are reported here.

Case Reports

Dale P., aged 5½ months, developed a fever of 102 F on October 7, 1940. He had one loose stool, was somewhat listless, but otherwise did not appear ill. He was examined on the day of onset and nothing abnormal was found. At this time his white blood count was 5,400 with 64 per cent lymphocytes. The parents were told that he probably had the "rose rash of infants" and that he would probably have fever for three days which would be followed by a drop in temperature and the appearance of a rash. He did have a fever for three days, and on the fourth day his temperature did fall to normal but no rash appeared.

On October 11, 1940, Delores, his twin sister, developed a temperature of 100 F in the evening. The next day the temperature rose to 103.2 F, on October 13, to 103.4 F, and on October 14, to 103.4 F. She was examined on October 14 and nothing unusual was found. At this time her white blood count was 3,600 with 82 per cent lymphocytes. Dale's white blood count at the same time (one week after the onset of his illness) was 9,700 with 82 per cent lymphocytes. On October 15 (four days after onset) Delores' temperature became normal and on October 16 a generalized roseola rash appeared, which lasted for forty-eight hours.

Second Attacks—These are infrequently described, but Zahorsky² states that he has seen the disease more than once in 2 children in 1 of whom he was not sure of the diagnosis. I have had the same experience.

In August, 1933, I saw Joan G., aged 10 months, because of fever and irritability of one day's duration. Physical examination showed nothing abnormal and the child was not very sick. A white blood count on this visit was 12,500. Two days later she still had fever and her white blood count had dropped to 6,700. On the fifth day the mother phoned and informed me that Joan was covered with a rash, like measles, that her temperature was normal, and that she felt well.

In June, 1939, Joan suddenly developed a high fever and had a convulsion. She was brought to the hospital where I first saw her. At this time her temperature was 104.6 F and her white blood count 8,800. The following day her temperature was still elevated and her blood count was 9,200. On the fourth day her white blood count dropped to 6,500 and her temperature came down to normal. She broke out in a generalized roseola rash that day, and on the fol-

mission, and blood findings are discussed. Several unsuccessful attempts to isolate the etiologic agent of the disease are described.

This clinical entity occurs frequently, most commonly in spring and summer, and affects children under 3 years of age. A three-day fever in a patient who does not appear ill, absence of physical findings, and a typical rash that appears after the fall in temperature are the characteristics of the disease. It is accompanied by a leukopenia and a lymphocytosis. It is infectious but the etiologic agent is not known. It has no complications, its treatment is symptomatic, and its chief practical importance is one of differential diagnosis, especially in the pre-eruptive stage.

MEDICAL PRACTICE AND OUR AGING POPULATION

For many years the average age of the American population has been increasing, and there is every indication that this trend will continue into the future. These changes in the age structure will profoundly affect our economy, our institutions, and our way of life, says the *Statistical Bulletin* of the Metropolitan Life Insurance Company. The impact will be felt especially in the field of medicine, because the prevalence and the character of sickness in the community are greatly influenced by the age composition of its people.

It is evident, therefore, that the aging of the population will have a marked influence on medical economics. As the proportion of older persons doubles in the course of the next genera-

tion, an increasing number of physicians and of hospital facilities will be required. A regional redistribution of physicians may be in order, in view of the increasing numbers of old people who locate in the South. As the proportion of younger persons declines, and there is increasing mastery over the acute diseases, physicians will have more time and inclination to devote to the chronic diseases. The total volume of illness will, however, increase because of the longer periods of disability which characterize these diseases. The changing situation will bring up new and vital problems of medical organization and personnel. It will be the better part of wisdom to study these problems carefully and make suitable provision for them in advance.

SCIENTIFIC EXHIBITS

1942 Annual Meeting

Applications for space for the scientific exhibits should be made directly to

Dr. J. G. Fred Hiss,
505 State Tower Building,
Syracuse, New York,

Chairman of Subcommittee on Scientific
Exhibits of the Convention Committee

The Annual Meeting will be held
April 27-30, 1942, Hotel Waldorf-
Astoria, New York, New York. The
list will be closed on January 1, 1942.

PETER IRVING, M.D., Secretary

tions should be increased, especially in the first day of the disease. Nevertheless, they do show the general trend of the blood reaction to the disease. In the first day, although the total white blood count shows considerable variation, there is a tendency for a relative leukopenia without much change in the differential count. The leukopenia becomes most marked by the third day and then returns to normal whereas the lymphocytosis becomes most marked later and persists longer than the leukopenia.

Diagnosis

From the practical standpoint roseola infantum is a diagnostic problem, and only a diagnostic problem, in its pre-eruptive stage. When the rash appears, anyone acquainted with the disease can almost make the diagnosis over the telephone.

In the majority of cases the diagnosis can be strongly suspected before the rash appears on the following bases: (1) age—child under three years, (2) fever—sudden onset and relatively high, (3) physical findings—absent or slight and child does not appear so ill as might be expected from the degree of fever, and (4) white blood count—relative leukopenia with a tendency to lymphocytosis.

After the rash appears, the diagnosis rests on the appearance of the exanthem and its occurrence after the fever has disappeared. At this stage the lymphocytosis is most marked.

Treatment

This is purely symptomatic, although acetyl salicylic acid almost specifically affects the temperature. Many of the youngsters who are old enough to be up and about continue to play and are much happier when not kept in bed. The course is not altered by rest in bed, and in many cases this is impossible.

Etiology

No etiologic agent of the disease has been identified. Because of the failure of routine bacteriologic methods to demonstrate a causative organism in the blood, stools, or throat of patients with the disease, an attempt was made to recover a filterable virus.

In measles, to which roseola infantum is somewhat analogous, a filterable virus has been isolated from patients in the pre-eruptive stage of the disease only. For this reason our attempts to recover a virus were limited to patients during the febrile period before the appearance of the rash.

In each of 3 infants the throat was swabbed with cotton saturated with meat extract broth, which was transferred to small tubes of the same media. This material was then filtered through small Seitz filters.

The filtrate was applied to the scarified cornea of rabbits and injected intracerebrally and intraperitoneally into rabbits, guinea pigs and mice.

The filtrate from 1 case was applied to the cornea of two rabbits and injected intracerebrally and intraperitoneally into each of six mice and two guinea pigs. Material from a second case was applied to the cornea of two rabbits. Material from a third case was inoculated intracerebrally and intraperitoneally into two rabbits, two guinea pigs, and six mice.

We are indebted to Dr Jerome Syvertson of the Department of Bacteriology of the University of Rochester for this bacteriologic investigation.

In addition to this, blood was obtained from 1 patient in the outpatient department of the Strong Memorial Hospital during the pre-eruptive stage and the serum was transferred to the chorioallantoic membrane of a chick embryo. In a fifth case the filtrate of throat swabbings was treated in a similar manner. The egg inoculations were done by Mr Charles Shepard, student fellow in the Bacteriology Department of the University of Rochester.

None of these attempts to demonstrate a filterable virus met with success.

Zahorsky² has mentioned the fact that in the families of children affected by the disease no illness is present preceding the onset of the child's symptoms in the majority of cases. This is our experience. In many cases the child has had no contact other than with the immediate family.

However, we know from Cushing's³ and Greenspan and Barenberg's⁴ reports and from the attack in twins, reported above, that the disease is definitely infectious. Greenspan and Barenberg felt that they could demonstrate a correlation between infection in various cottages in the infant's home from which their cases were reported with carriers among the adult attendants of these children. This would seem, at the present time, the most reasonable explanation for the transfer of this interesting disease.

Summary

One hundred and eleven cases of roseola infantum are presented. The age, frequency, seasonal variation, symptomatology, trans-

mission, and blood findings are discussed. Several unsuccessful attempts to isolate the etiologic agent of the disease are described.

This clinical entity occurs frequently, most commonly in spring and summer, and affects children under 3 years of age. A three-day fever in a patient who does not appear ill, absence of physical findings, and a typical rash that appears after the fall in temperature are the characteristics of the disease. It is accompanied by a leukopenia and a lymphocytosis. It is infectious but the etiologic agent is not known. It has no complications, its treatment is symptomatic, and its chief practical importance is one of differential diagnosis, especially in the pre-eruptive stage.

MEDICAL PRACTICE AND OUR AGING POPULATION

For many years the average age of the American population has been increasing, and there is every indication that this trend will continue into the future. These changes in the age structure will profoundly affect our economy, our institutions, and our way of life, says the *Statistical Bulletin* of the Metropolitan Life Insurance Company. The impact will be felt especially in the field of medicine, because the prevalence and the character of sickness in the community are greatly influenced by the age composition of its people.

It is evident, therefore, that the aging of the population will have a marked influence on medical economics. As the proportion of older persons doubles in the course of the next genera-

tion, an increasing number of physicians and of hospital facilities will be required. A regional redistribution of physicians may be in order, in view of the increasing numbers of old people who locate in the South. As the proportion of younger persons declines, and there is increasing mastery over the acute diseases, physicians will have more time and inclination to devote to the chronic diseases. The total volume of illness will, however, increase because of the longer periods of disability which characterize these diseases. The changing situation will bring up new and vital problems of medical organization and personnel. It will be the better part of wisdom to study these problems carefully and make suitable provision for them in advance.

SCIENTIFIC EXHIBITS

1942 Annual Meeting

Applications for space for the scientific exhibits should be made directly to

Dr J. G. Fred Hiss,
505 State Tower Building,
Syracuse, New York,

Chairman of Subcommittee on Scientific
Exhibits of the Convention Committee

The Annual Meeting will be held
April 27-30, 1942, Hotel Waldorf-
Astoria, New York, New York. *The
last will be closed on January 1, 1942*

PETER IRVING, M.D., Secretary

Case Reports

INTRAPERITONEAL ACTINOMYCOSIS

RICHARD A. LEONARDO, M D, CH M, F I C S, Rochester, New York

ACTINOMYCOSIS is rare enough, and the abdominal form occurs in only 20 per cent of the cases. Intrapertoneal actinomycosis due to the liberation of the *Streptothrix actinomyces* from the human intestinal canal via the perforation of an acute appendicitis is, obviously, rarer still. For this reason the case may warrant reporting, besides, the case is of interest because of the great difficulties encountered before successfully reaching the correct diagnosis and also because of the failure of all recognized forms of treatment to prevent a fatal termination.

Case Report

E. A., a white man aged 30, sought hospital admission on November 7, 1933, for the relief of his complaint of acute abdominal pain of two days' duration. Clinical symptoms and physical examination were suggestive of an ordinary acute appendicitis, and an appendectomy was done through a McBurney incision. At operation the appendix was found to be perforated with a moderate amount of localized peritonitis surrounding that area. On the fifteenth postoperative day he was discharged, although the wound was still draining. When he was seen some three months later, the wound was all healed and his only complaint was persistent constipation. When seen again about six weeks later he complained of "sciatica" in the right hip and leg and also of pain in both buttocks and knees. He gave a history of having lost over 25 pounds in weight since date of operation and stated that he had never felt well since the appendectomy had been done.

A physical examination on May 29, 1939, at the time of readmission to the hospital, was as follows: temperature, over 102 F., pulse, 112, respirations, 24. General appearance was one of marked cachexia with slight flexion deformity and lateral rotation of the right hip, which was held rigidly in this position and was painful on passive movement. Except for a few rales at the bases of both lungs, the chest, including the heart, was entirely negative. Tenderness was present over the appendectomy scar and in the right sacroiliac region, extending downward into the right hamstring muscles.

The important laboratory findings were as follows: white blood count, 28,700 (March 29, 1939) and 15,500 (November 16, 1939), red blood cells, 3,600,000, chest and abdominal x-ray films, negative, barium enema showed stricture of upper rectum from unknown "outside cause", cultures from wound of first exploratory laparotomy (April 1, 1939) were negative. An x-ray of the chest (October 13, 1939) showed no evidence of actinomycosis, but pathologic sections from a biopsy of the sinus tract over the ileum revealed the typical sulfur granules of actinomycosis (October 9, 1939). The patient had previously had a second exploratory lapar-

otomy on April 16 and a third one on September 14, 1939—each one failing to find sufficient evidence to establish a definite diagnosis. At the first exploratory operation (April 1) an organized mass of inflammatory adhesions was found in the pelvis, at the second exploratory operation (April 16) several swollen lymph nodes were removed from the mesentery for biopsy (pathologic report was naturally negative because the actinomyces is too large to pass through the lymphatics), at the third exploratory operation (September 14, 1939) nothing of diagnostic importance was found, but a biopsy taken from the resultant sinus tract (from this operation) showed typical actinomyces (October 9, 1939). The patient had several sinuses because the laparotomy incisions all failed to heal and, besides, several localized abscesses had been drained with resultant sinus tracts—notably, an abscess over the right buttock which was incised and drained June, 1939, and a large abscess over region of right hip, which was incised August 15, 1939, with a persistent sinus resulting from each incision.

Treatment—At one time or another the patient received almost all of the recognized forms of treatment, but to no avail. The wounds were irrigated with Dakin's solution, frequent blood transfusions were given, an intensive course of thymol therapy was given, iodides were administered in large quantities, both by mouth and intravenously, and two prolonged courses of sulfanilamide therapy were given (using large doses)—all without any apparent benefit to the patient. We were about to start x-ray treatment (recently recommended by McKee, staff members of the Mayo Clinic, and others) when the patient took a sudden turn for the worse. He died on Christmas day in 1939.

Autopsy—An autopsy was done at the Monroe County Hospital under the direction of Dr. W. S. Thomas, pathologist. A summary of the autopsy report follows: Beginning actinomycosis was found in both lungs together with bilateral pneumothorax, there were several infected sinus tracts in the lower part of the abdominal wall and over the buttocks, some of the tracts leading into the pelvis, fistulas were found in the large bowel, and a large, granulomatous tumor was present in the pelvis, involving both the rectum and the sigmoid colon. Peripheral edema and a generalized arteriosclerosis completed the pathologic picture.

Conclusion

An unusual and fatal case of intraperitoneal actinomycosis, caused by ruptured, acute appendicitis, is reported. The case is of interest not only because of its relative rarity but because of the difficulties encountered before it was possible to reach the correct diagnosis and also because of the obvious failure of various forms of therapy previously reported as beneficial in other cases.

ACUTE BACTERIAL ENDARTERITIS OF A PATENT DUCTUS ARTERIOSUS

WILLIAM TRAVIS GIBB, JR., M.D., New York City

THIS paper presents an instance in which a patent ductus arteriosus was found as the only congenital abnormality in the heart of an older individual, and it re-emphasizes the pronounced vulnerability of such a lesion to the superimposition of an acute bacterial process. It also shows that when such a lesion is discovered clinically the possibility of a bacterial complication may be seriously considered and operative interference entertained before such a development has taken place.

A reawakening of interest has recently been effected in the study of anomalous formations of the heart and its vessels. Within the past few years the surgical approach to this difficult problem has brightened the seemingly hopeless outlook of patients with such lesions. The common incidence of congenital heart disease makes its consideration of great importance, both from an anatomic and therapeutic standpoint. This fact combined with a more optimistic attitude toward the life expectancy of these individuals, created by a promising operative correction, should prove motivation enough for a renewed consideration of these abnormalities.

To Maude Abbott^{1,2,3,4} should be attributed the major credit for the exhaustive anatomic analysis of this subject. Her studies have shown a significantly frequent incidence of patent ductus arteriosus, an anomaly that forms the basis of this report. Of the 1,000 cases of congenital cardiac defects which she reviewed, 242 cases of patent ductus arteriosus were encountered, approximately 150 of which were associated with other varieties of congenital defects. The hearts of 92 were the seat of patent ductus arteriosus alone or in association with only minor anomalous formations. Twenty of these 92 subjects had died before the age of 5, while the remaining 72 cases had succumbed to the effects of their anomalies either in later childhood or in their early adult years. It is noteworthy that about 27 cases of this group died because of the presence of a bacterial endarteritis, 16 succumbed suddenly due to their cardiac abnormalities, while 24 were victims of a prolonged bout of cardiac failure. Sixty-six cases out of this group died, at an average age of 24 years, of a cause attributable, directly or indirectly, to the congenital defect. This cogently portrays the gravity of the lesion and stresses the importance of a vigorous reconsideration of the problem.

In view of the generally accepted belief that patent ductus arteriosus or any other anomalous formation of the heart is usually found as one of multiple defects, it becomes important to realize the point emphasized by the Abbott series—that any of these lesions may exist

alone—and indicates that the possibility of the presence of an isolated lesion should be considered in formulating a decision of the operability of a given case.

Case Report—From the Knickerbocker Hospital, New York City

W K, a white man aged 51, was admitted to the Knickerbocker Hospital on December 28, 1937, complaining of fever, pain in the back of his neck, and hoarseness of ten days' duration. His family history was irrelevant and, aside from a bilateral herniorrhaphy in 1930, the past history was negative. The patient had always been in good health and had been able to indulge in all the usual forms of muscular activity of childhood and adult life. Ten days prior to admission he first noticed that he had a fever, then pain in the upper cervical region of his neck and a gradually increasing painless hoarseness made their appearance. The degree of the pain remained constant, but the hoarseness became progressively worse. His temperature during this ten-day period reached the level of 104 F at night and would drop as low as 98 F in the morning. During this ten-day period he had received nothing but fluids by mouth and had had frequent enemas, with the result that upon admission his stools were watery in character.

Examination showed a well-developed adult white man lying quietly in bed apparently acutely ill but not in pain. There was no cyanosis or pallor. His pupils were equal and round and reacted both to light and accommodation. There was no discharge from the ears or nose, the nasopharynx was normal. Slight tenderness was elicited on pressure in the upper cervical portion of his neck, but there was no rigidity or lymphadenopathy. The lungs were clear throughout. The cardiac apex was within the midclavicular line. The sounds were regular and of fair quality. There were no murmurs audible. The abdomen was soft, and there were no masses or tenderness. His liver edge was felt three fingers breadth below the costal margin and was smooth, firm, and sharp. Knee jerks, ankle jerks, Babinski, abdominal, and cremasteric reflexes were all negative.

A urinalysis showed a trace of albumin, a few white blood cells, and an occasional red blood cell. A blood count disclosed a hemoglobin of 86 per cent (Sahli), 4,250,000 red cells, and 8,400 white cells per cubic millimeter. A differential study of his blood smear revealed 76 per cent polymorphonuclear leukocytes and 24 per cent lymphocytes. Agglutination reactions were negative for typhoid, paratyphoid A and B, typhus, and Brucella abortus. A blood culture revealed 1,200 colonies of *Staphylococcus albus* per plate in twenty-four hours. These findings were repeatedly substantiated. Cultures of his nose and throat showed *Staph aureus* predominantly. X-rays of the sinuses showed cloudiness of the frontals, ethmoids, and sphenoids. A teleroentgenogram revealed the

heart to be somewhat enlarged to the left. Increased vascular markings of the pulmonary field were also noticed bilaterally. A small, roughly rounded infiltration was seen at the left lung base and another similar infiltration in the second right interspace.

Temperature on admission was 104.2 F and remained elevated throughout his entire stay in the hospital. Two days after admission evidence was elicited of an area of consolidation in the right lower lobe, and three days later cyanosis appeared and became rapidly progressive. Abdominal distention and extension of the area of consolidation at the right base soon followed. Finally, sonorous and sibilant rales became diffusely audible over both lung fields, he gradually became more and more toxic and, finally, died eleven days after his entrance to the hospital. The day before his demise a great number of petechiae appeared over his back and several were noted in his conjunctivas. His death occurred notwithstanding treatment with protosil, prontosil, Staph albus antitoxin, Staph aureus bacteriophage, etc.

Necropsy—The skin showed innumerable petechiae, which were mostly situated upon the posterior aspect of the body. There were two conjunctival petechiae. Scattered petechiae were also seen over the peritoneum, while the small intestine showed many scattered, flame-shaped, and occasionally more irregular subserosal hemorrhages. The right pleural space was completely obliterated due to the presence of stout, bandlike adhesions. The left pleural space showed a similar process in its upper two-thirds, there was approximately 200 cc of turbid, straw-colored fluid in this hemithorax. The pericardial sac contained about 200 cc of clear, straw-colored fluid. The anterior aspect of the visceral pericardium showed oval and rounded zones of thickening. The heart was moderately enlarged. This enlargement was mainly due to thickening of the right ventricle and the prominent dilatation of the right cardiac chambers. The left ventricular wall was normal in width. On section, the myocardium was diffusely reddish brown, except here and there where a few submillary-sized, partially necrotic yellow nodules were encountered. A small number of fine nodular foci that had produced slight elevations of the endocardium were found subendocardially. The mitral valve showed some thickening of its anterior leaflet due to the interstitial deposition of a few rhomboid and a few more irregular arteriosclerotic plaques. There was no thickening of its chordae tendineae. The left auricular endocardium was smooth throughout. The foramen ovale was found closed. The papillary muscles and the trabeculae carneae of the left ventricle showed no gross abnormalities. The aortic valves showed a minimal thickening along the site of the fibrous decussations of the posterior cusp but, otherwise, were normal. The pulmonary conus and the lumen of the main branch of the pulmonary artery were distinctly widened and the intima of this section of the artery was thickened. However, there was no apparent thickening of the pulmonary cusps. Situated at the site of the ductus arteriosus, which was found to be patent, admitting a stout probe, there was a large, fleshy, mottled pink thrombus. A small

quantity of this thrombotic material was also found in the pocket produced by the ducts along the intimal surface of the aorta. This main thrombotic mass, however, was found to be situated definitely on the pulmonary side. The endocardium of the outflow tract of the right ventricle showed a slight degree of thickening. The tricuspid valve, except for some slight opacity of the septal leaflet, showed no abnormalities, its chordae tendineae were normal. The endocardium of the right auricle was diffusely gray and smooth. The coronaries throughout, except for some slight, asymmetrical, intimal thickening of the anterior descending branch of the left coronary artery, presented no abnormalities. The aorta in its descending portion was the seat of a few superficially ulcerated and hemorrhagically discolored arteriosclerotic plaques and several scattered intimal hemorrhages.

Throughout both lungs there were a number of infarcts that were well demarcated. On section, the centers showed liquefaction and necrosis. A small artery with an occluding thrombus was found leading to one of these. In another a small venous tributary was completely occluded by a mottled gray and red thrombotic mass. The lower portions of both lungs were completely airless and throughout this area there were numerous areas of hemorrhagic bronchopneumonia. In addition, there was a widening of the bronchial passages, while the terminal portions of the bronchi showed circular areas of dilatation. The walls of these affected bronchi were thinned, their mucosal surfaces were covered with a gray, mucopurulent material. The tracheobronchial mucosa throughout was markedly edematous, granular, and irregularly hemorrhagic and covered with a large amount of mucopurulent material. The regional tracheobronchial lymph nodes were moderately enlarged, soft, and discrete. The liver showed evidence of chronic passive congestion and a moderate degree of fatty change. The spleen was enlarged and showed two wedge-shaped, hemorrhagic, and lemon yellow infarcts. The kidneys presented several infarcts that were more hemorrhagic than those in the spleen. There were also many scattered, fine, flame-shaped, cortical hemorrhages that extended to a slight degree toward the medullary portion. Innumerable petechial hemorrhages, many of which were yellow-centered, were observed in the mucosa of the small intestine. The brain on section disclosed some fine, punctate hemorrhagic areas in the gray matter.

The anatomic diagnoses were chronic diffuse mucopurulent tracheobronchitis with secondary bronchiectasis, septicemia (Staph. albus) clinically, acute bacterial endarteritis (Staph. albus) of pulmonary artery superimposed on a patent ductus arteriosus, with extension into aorta, multiple infected pulmonary infarcts with secondary phlebitis of small pulmonary vein, patchy hemorrhagic bronchopneumonia, left hydrothorax (200 cc), multiple infarcts of spleen and kidneys, multiple focal abscesses of cerebral cortex and myocardium, multiple petechiae of skin and intestines, acute infectious splenitis with splenomegaly (450 Gm.), passive congestion and fatty change of liver, bilateral

adhesive pleuritis, status seven years post-bilateral herniorrhaphy

Comment

The case herein presented is illustrative of an individual who had had an uncomplicated patent ductus arteriosus for a period of fifty years before the superimposition of an acute bacterial endarteritis that had involved the pulmonary artery in the region of the ductus and had extended into the ductus itself and a small part of the aorta. It is noteworthy that the cardiac valves were entirely free of any bacterial involvement, nor did they show any evidence of any other disease process except for some thickening due to tension and arteriosclerosis. In view of the fact that no primary source for this infection other than an extensive bronchial inflammation was found at autopsy, the obvious explanation is that a transient bacteremia arose from such a source and produced the acute endarteritis of the patent ductus arteriosus. It also appears that the involvement of the pulmonary artery was responsible for the infarcts of the lung and that the extension of the bacterial lesion into the aorta and the associated pulmonary vein phlebitis led to the systemic involvement.

Deserving of mention is the fact, substantiated by three different observers, that at no time during the course of the acute disease was a cardiac murmur of any type audible. The explanation for this discrepancy was apparent in retrospect upon examining the heart at necropsy. It was found then that the entire lumen of the ductus was occluded by vegetations, and it was the assumption, therefore, that very little blood had been permitted to pass through this arteriovenous shunt. Furthermore, there was no history of any typical murmur being heard in the past although on the basis of the anatomic findings it is reasonable to believe that it must have been there. Moreover, the dilatation of the pulmonary artery and pulmonary conus offers strong anatomic evidence for the belief that the ductus arteriosus was patent for a considerable time prior to the onset of the endarterial infection. This contention was fortified by the hypertrophy and dilatation of the right cardiac chambers, which is certainly indicative of the long-standing anomalous shunting of the blood stream.

The reports of Dolley and Jones,⁶ Gross,^{4,7,8} and others concerning the surgical approach to the problem of patent ductus arteriosus are of the greatest importance. The opening of the left side of the upper anterior part of the chest wall, with ensuing collapse of the lung, produces an excellent exposure of the patent ductus and the structures immediately surrounding it. The ligation of the ductus itself, especially if its wall

is thin and friable due to its being already involved by a bacterial endarteritis, is the most hazardous part of the procedure. Hemorrhage may be fatal or difficult to control. The lumen of the ductus is funnel-shaped with the wider end originating from the aorta. Its length may vary from 2.25 to $1\frac{1}{2}$ cm and the wall is usually as thick as that of a vein. Sclerosis and calcification, especially in older cases, may occur at the aortic end and extend inward as much as 1 cm., this fact is of significance because of its effect upon a superimposed bacterial endarteritis, although the vegetations usually begin at the pulmonic end and may only involve the walls of the pulmonary artery in the immediate vicinity and leave the valves entirely free. Although there have been reports of successful operative procedures upon patients with bacterial involvement of the ductus, the really important approach to the problem is the obliteration of this passage before infection or cardiac failure has taken place. Gross has stated that in suitably worked up and selected cases an experienced surgeon should have a mortality rate of only 10 per cent, and that the closure should preferably be done between the ages of 6 and 7 years.

Aside from the usual contraindications to any extensive surgical procedure, the presence of other serious congenital abnormalities, such as coarctation of the aorta proximal to the opening of the ductus or congenital stenosis of the pulmonary valve, is an absolute contraindication, for in these conditions the shunt probably acts as a compensatory mechanism and the closure of it would be followed by fatal consequences. Therefore, it is of the greatest importance to exclude the possibility of any such accompanying defect, which in many instances is difficult. It is interesting to note in this connection that in Abbott's series almost all of the individuals with such serious complicating defects died before the age of 5.

The real difficulty lies not in the accurate diagnosis of the lesion or in the determination of the optimum time for operation but, rather, in persuading the parents of apparently healthy young individuals to allow them to be subjected to a serious operative procedure carrying with it a formidable mortality rate.

PERIPHERAL NEURITIS FOLLOWING THE USE OF SULFAMETHYLTHIAZOLE IN A CASE OF SUBACUTE BACTERIAL ENDOCARDITIS

EMANUEL APPELBAUM, M.D., New York City

RECENTLY, two new sulfanilamide derivatives, sulfathiazole and sulfamethylthiazole, have been presented to the profession for clinical investigation. Like sulfanilamide these drugs are effective against experimental streptococcal infections and, like sulfapyridine, they have a pronounced antipneumococcus action, but unlike either of these preparations they are said to exert a marked effect upon staphylococci, both in vitro and in vivo. Experimentally, the thiazole derivatives have been shown to be less toxic than either sulfanilamide or sulfapyridine. Both thiazole compounds are said to show much less acetylation than sulfapyridine. The following report is offered as a probable case of intoxication following the use of sulfamethylthiazole.

Case Report

M. W., a man aged 21, was admitted to Sydenham Hospital on October 22, 1939, complaining of fever, night sweats, weakness, general malaise, painful red spots on the finger tips, and pain in the left upper abdominal quadrant of ten weeks' duration. For the past few days he also had cardiac palpitation. The fever was irregular, reaching, at times, 104 F. The asthenia became progressively more marked. He gave a past history of rheumatic fever at the age of 9 years.

Physical examination revealed a well-nourished but pale young adult, appearing chronically ill. The pupils reacted to light and accommodation. The conjunctivae and fundi were normal. The lungs were clear. The heart was moderately enlarged and showed harsh systolic and rumbling diastolic murmurs at the apex and also systolic and diastolic murmurs over the aortic area. The heart rate was 110, with a regular sinus rhythm. The blood pressure was 150 systolic and 50 diastolic. There was sternal tenderness. The spleen was slightly enlarged and tender. The liver was not felt. There were a few small red nontender spots in his finger tips, there was slight clubbing of the fingers. There was no paralysis or paresis, and the reflexes were normal. There were no pathologic reflexes, and the temperature ranged between 101 and 104 F. A diagnosis of subacute bacterial endocarditis was made.

The white blood count was 8,800, with 67 per cent polymorphonuclears, the red blood count was 3,700,000, with 60 per cent hemoglobin. The urine examination was essentially negative, and the blood culture was positive for *Streptococcus viridans*. This confirmed the clinical diagnosis.

As soon as the diagnosis of subacute bacterial endocarditis was established, the patient was started on sulfapyridine, receiving 1 Gm every four hours. On November 3, following eleven days of chemotherapy, his white blood count dropped to 3,800, and several days later it dropped to 1,500. The neutrophils were 13 and 30 per cent, respectively. The sulfapyridine was immediately discontinued.

Following a course of pentnucleotide and a series of transfusions, the neutropenia showed gradual and progressive improvement. When the white blood count reached 9,400, the chemotherapy was resumed. He received sulfapyridine orally for one week, and for more than two weeks he was given neoprontosil parenterally in addition to the sulfapyridine. This regimen was followed by a course of sodium sulfapyridine by vein, 5 Gm daily, in conjunction with the oral use of sulfapyridine, 4 to 6 Gm a day.

The program of intensive chemotherapy was continued uninterrupted from November 18, 1939, to January 2, 1940. The clinical picture throughout this period remained essentially unchanged. The temperature ranged between 99 and 103 F. There were frequent new crops of tender nodes on the palms of his hands and on the finger tips. On December 11 he showed evidence of splenic infarction. The neurologic examination was entirely negative.

The blood cultures were persistently positive for *Str. viridans*, showing from 100 to 280 colonies per cubic centimeter. The white blood count ranged between 5,600 and 7,350, with 75 to 80 per cent neutrophils. The red blood count ranged between 2,800,000 and 3,900,000, with the hemoglobin between 43 to 65 per cent. The urine showed a trace of albumin, 10 to 15 red blood cells, occasional hyaline and granular cast, and 4 plus urobilinogen. The blood sulfapyridine levels were always low, averaging 2 mg per hundred cubic centimeters. The electrocardiogram showed slurring QRS in leads I and II and notching in lead III deep Q₃ and Q₄ and elevated S-T intervals in leads II and III.

On January 3 the patient was started on sulfamethylthiazole.* He received at first 6 Gm., and later from 8 to 12 Gm., per day. This drug was continued until January 25 when it was stopped because of a drop in the white blood count to 2,800, with 47 per cent polymorphonuclears. A course of pentnucleotide was again instituted. Five days later his white blood count was 3,200, with 70 per cent polymorphonuclears.

The total amount of sulfamethylthiazole received over a period of twenty-three days was 197 Gm. This drug appeared to have no influence on the clinical course, which continued to progress insidiously. The positive blood cultures persisted but showed somewhat fewer colonies, 104 to 137 per cubic centimeter.

On February 1 the patient showed impaired adduction in both thumbs. This was the first indication of peripheral neuritis but was not properly evaluated at the time. Several days later he developed pains in the lower extremities and bilateral foot drop. At about the same time he also developed signs of left pulmonary infarction with pleural effusion.

Unfortunately, the use of sulfamethylthiazole, which was resumed on February 1, was not con-

* The sulfamethylthiazole was generously furnished by the Winthrop Chemical Company.

sidered at that time as a possible etiologic factor of the peripheral neuritis and was, therefore, continued until the middle of March.

Neurologic examination on March 9 revealed flaccid paralysis of the lower extremities, with predominant involvement of the extensor muscles of the feet. The hand grip was weak on both sides, and there was loss of abduction and adduction in the fingers of both hands. Sensation was diminished in both upper and lower extremities. The biceps reflexes, knee jerks, and ankle jerks were all absent. There were no pathologic reflexes.

The spinal fluid showed a slight increase in the protein but was otherwise normal. The white blood count ranged between 6,000 and 8,000, with 70 per cent polymorphonuclears. The red blood count was 2,700,000 with 53 per cent hemoglobin. The blood sulfamethylthiazole level was 3.4 mg per hundred cubic centimeters. The blood nonprotein nitrogen was 26.6 and the urea 9.5 mg per hundred cubic centimeters. The blood cultures remained positive for *Str. viridans*.

The patient's general condition became progressively worse. There were numerous embolic

phenomena with multiple infarctions. He died in circulatory failure on March 30. A necropsy was not obtained.

Comment

This case illustrates some interesting and important points. Although the patient developed a marked neutropenia as a result of sulfapyridine intoxication, he was, after a period of interruption, able to resume and continue taking the drug with impunity. Likewise, the moderate neutropenia which followed the sulfamethylthiazole did not recur upon resumption of this chemical. As has been noted by several observers, the bacterial endocarditis failed to respond to a prolonged and intensive course of chemotherapy, including sulfapyridine, sodium sulfapyridine, neoprontosil, and sulfamethylthiazole. It seems reasonable to assume that the peripheral neuritis probably resulted from excessive ingestion of sulfamethylthiazole (197 Gm in twenty-three days).

910 Park Avenue

THREE CASES OF VENTRICULAR FIBRILLATION

One Electric Shock and Two Coronary Occlusions

BEVERLY L. VOSBURGH, M.D., Schenectady, New York

Case 1—On February 17, 1932, D. L. R., a man aged 25, was rendered unconscious by an electric shock estimated at 3,000 volts, 60-cycle alternating current. For the first two or three minutes there were intermittent, spasmodic, extremely deep respiratory efforts, entirely lacking in rhythm and failing to relieve the dusky, cyanotic, slate color present in his face and neck. An electrocardiogram taken within eight to ten minutes revealed ventricular fibrillation instead of normal complexes (Fig. 1).

Case 2—On November 22, 1935, A. N., a man aged 35, was brought to this hospital complaining of the characteristic symptoms of acute coronary occlusion. After opiates were administered, an electrocardiogram was taken (see Fig. 2). About two hours later, as we were about to repeat the electrocardiogram, the patient suddenly died. With the electrodes already in place ventricular fibrillation was recorded (see Fig. 3, page 1866).

Case 3—On March 2, 1936, T. R., a man aged about 45, was brought to this hospital with a history suggesting coronary occlusion three days before and again the night previous. His immediate complaint was a sense of sternal oppression. The standard three leads of the electrocardiogram had been completed (see Fig. 4) and a fourth lead was in process when the patient had a convulsion and died. The tracing was taken as soon as the convulsive seizure had ended (see Fig. 5). The record is characteristic of ventricular fibrillation.

Summary and Comments

Three cases of ventricular fibrillation are presented. Case 1 followed electric shock, and Cases 2 and 3 followed coronary occlusion of the deep sino-spiral muscle (DSS) and deep bulbo-spiral muscle (DBS) types, respectively (Robb and Robb). Dresbach, Langworthy and Kouwenhoven, Williams and Wiggers have all demonstrated that ventricular fibrillation is usually the mechanism of death in low-voltage shocks. It is an interesting sidelight that suitable countershock stops the fibrillation in most attempts experimentally.

The other 2 cases of ventricular fibrillation followed acute coronary occlusions where the DSS and the DBS were involved. According to Robb and Robb all cases of the DSS type coming to autopsy died because of the infarction after periods ranging up to about two weeks. This case survived only two hours.

VENOUS ANEURYSM AS A FACTOR IN THE DIAGNOSIS OF FEMORAL HERNIA

Report of Two Cases

LEONARD K STALKER, M D, Rochester, New York

CIRSOID enlargement of the great saphenous vein at the fossa ovalis may be mistaken for femoral hernia. These enlargements or venous aneurysms may form a definite bulging which, with the patient standing, gives grossly the appearance of a femoral hernia. An impulse is obtained on coughing in both instances, which is confusing. Differential diagnosis, however, is easily made, and in all cases of suspected femoral hernia the great saphenous system should be investigated before operation is advised. This is done with the patient standing upright before the examiner with both legs fully exposed from the ground upward. The fingers of one hand are placed over the bulge at the groin, while the fingers of the other hand percuss a segment of vein in the leg below. If an impulse can be picked up by the fingers of the lower hand or if, by reversal of the procedure, an impulse can be felt in the upper hand, incompetency of the saphenous system is present, and this bulge must be suspected as being a venous aneurysm.

If a hernia is present, when pressure is made by the palpating finger on the bulge it can either be reduced or a sense of increased resistance will be present. If, on the other hand, a venous aneurysm is present, the resistance remains the same throughout the bulge, but when the patient reclines the dilation quickly decreases in size but does not entirely disappear. Cirsoid dilations of this type are always associated with incompetency of the saphenous system and varicosities of the lower extremities. I have recently performed a secondary operation on 2 patients who had had surgical treatment elsewhere for a supposed femoral hernia.

Case Reports

Case 1—A woman, aged 45, had had varicosities of both lower extremities for a period of eight years. These had increased in severity, and a few months before coming to me for treatment a bulge was noted in the left femoral region. She consulted a physician elsewhere, and the diagnosis of femoral hernia was made. Operation was performed elsewhere for this condition. The postoperative course was prolonged by a superficial thrombophlebitis of the left leg and a secondary wound infection. The patient states that she was aware that the same bulge was present in the left femoral region as soon as the dressings had been permanently removed.

It was for this reason I was consulted. My examination revealed a well-appearing woman who had moderate varicosities of both lower extremities with an associated incompetency of the great saphenous vein on the left side. There

was an oval bulge that gave an impulse on coughing in the region of the left fossa ovalis. The diagnosis was an incompetent left great saphenous vein with associated venous aneurysm.

Under local anesthesia, incision was made directly over the fossa ovalis. A great deal of scar tissue was encountered, which made the dissection more difficult. A cirsoid venous enlargement approximately 4 cm in diameter was exposed. This enlarged some two or three times on coughing or straining. The dilated portion of vein was exposed back to its junction and was demonstrated to be the upper portion of an incompetent lateral superficial femoral vein, which entered the great saphenous vein on its lateral and anterior aspect almost at the saphenofemoral junction. The great saphenous vein was dilated some four times its normal size but was much smaller than the superficial femoral vein. Both were divided and ligated. The aneurysmal portion of the superficial femoral vein was excised, and 2 cc of a 5 per cent solution of sodium morrhuate was injected into the distal portion of this vein. A combined division, ligation, and injection of the great saphenous vein, together with separate division and ligation of its uppermost tributaries, were performed after a technic previously described.¹ Before closure of the incision the patient was asked to cough, and all evidence of venous bulging had disappeared. The patient was allowed to be ambulatory and was given subsequent injections of sclerosing solution in the office. The operation completely relieved her symptoms as well as all evidence of bulging in the left femoral region.

Case 2—A woman, aged 50, had had varicose veins in the left lower extremity for a period of five years. Three months previous to my examination she had noted a bulge in the left femoral region, and operation for left femoral hernia had been performed elsewhere. She made an uneventful convalescence following this operation, but on discharge from the hospital she noted the same bulge in her left femoral region. It was for this reason that I was consulted. My examination revealed a well woman who had moderate varicosities of the left lower extremities. These were associated with an incompetent great saphenous vein and a cirsoid dilation of the proximal portion of this vein.

Under local anesthesia, the saphenofemoral junction was exposed, and a cirsoid dilation of the proximal 4 to 5 cm of the great saphenous vein was found (Fig 1). This dilation was twelve to fourteen times the normal size of a great saphenous vein. Below the dilated area the saphenous vein was approximately four times its normal size. The entire aneurysmal dilation was excised, and a combined division, ligation, and injection of the great saphenous vein at the saphenofemoral junction were per-

formed. Four cubic centimeters of a 5 per cent sodium morrhuate solution was injected into the distal portion of the saphenous vein. Subsequent obliterative therapy was carried out in the office, and the patient has been completely relieved of her symptoms.

Comment

These circoid enlargements of the proximal portion of the saphenous vein or its associated tributaries are not uncommon findings. I believe these 2 cases serve to illustrate how such a condition can be mistaken for a femoral hernia.

It is possible that the two conditions might be associated, but in such instances differentiation would not be difficult. In each of these cases the same bulging and symptoms were present following herniotomy as were present before operation. I feel certain that it is safe to assume that the original diagnosis of the femoral hernia was incorrect. In each instance, I have confirmed this by communication with the physician who performed the operation for femoral hernia. This condition should be excluded in all cases in which the diagnosis of femoral hernia is considered, especially if varicosities are present in the involved extremity.

These 2 cases demonstrate the necessity for such consideration.

DOCTORS WHO FAVOR EUTHANASIA

More than 3,000 New York State physicians favor legalization of euthanasia or "merciful release" for sufferers from incurable disease who demand it, according to a poll by the Euthanasia Society of America, announced May 22 at the Society's annual meeting, held at its headquarters, 136 East 57th Street. Results of the poll were included in a report of the Society's Board of Directors presented by its president, Dr. Clarence C. Little, says the *New York Medical Week*.

Eighty per cent of the physicians of the state who replied to the Society's questionnaire stated that they believe the law should be amended to remove the penalty for criminal action now existing and permit physicians, with strict safeguards against abuse, to administer euthanasia to adult incurable sufferers.

In reply to a further question, "Is it a humane act for a physician to shorten the life of a patient suffering from an incurable painful disease like advanced inoperable cancer, who pleads with him to do so?" 3,144 physicians answered "Yes" and 337 "No."

"A measure demanded by such a large body of informed professional opinion deserves con-

sideration by the legislature of the state," the report pointed out.

Mrs. Leslie J. Tompkins, legislative chairman, stated in her report that the Society hopes to have introduced at the next session of the New York legislature a bill to legalize euthanasia.

The report of a Committee on Policy, read by Mrs. Louis deB. Moore, stated that a number of physicians have indicated that they favor broadening such a bill to legalize euthanasia administered by physicians to infants born grossly defective.

Among the New York City physicians who are serving on the Advisory Council of the Euthanasia Society of America are Drs. Theophilus P. Allen, Theodore Bliss, George L. Brodhead, Louis Carp, Russell L. Cecil, James A. Corcoran, Joshua W. Davies, Louis B. Dunn, John F. Erdmann, Frederick J. Farnell, John H. Garlock, Hirsch Loeh Gordon, R. Houghton Hooker, Lawrence S. Kubie, Max Lederer, Earle H. Mayne, Edwin P. Maynard, Harold R. Merwarth, Woodbridge E. Morris, N. P. Rathbun, Alan DeF. Smith, Philip Moen Stimson, Fenton Taylor, Giles W. Thomas, Norman E. Titus, and David M. Weeks.

Adequate rest is still the basis of all therapy of tuberculosis.—Charles K. Potter, M.D., *Contact*, February, 1941.

The Fourth Annual Forum on Allergy will be held in Detroit, Michigan on January 10 and 11, 1942.

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Date April 15, 1941

Presiding Dr Herman O Mosenthal

History

DR ROBERT McGRATH A 19-year-old, single, white woman was admitted to the hospital for the fourth time and died ten days later. The chief complaints at this time were hardening of the skin of five years' duration, dizziness, headaches, and shortness of breath for six months. The patient was well until the age of 13, when generalized weakness and lassitude developed. Examination by her family physician revealed an anemia for which iron was prescribed. There was no improvement, and she began to have attacks of diarrhea without melena lasting one or two days and unrelated to the iron medication. At the age of 14 she noticed stiffness of the hands, arms, and legs, for which she visited a clinic of another hospital where a fairly severe hypochromic anemia and scleroderma were noted. It was also observed that the hands became red and painful on exposure to cold. At that time the blood pressure was 110/80 mm Hg. Free hydrochloric acid was present in the gastric contents. The basal metabolic rate was 15 per cent below the average normal. The serum calcium was 10.8 mg per hundred cubic centimeters, phosphorus 4.9 mg per hundred cubic centimeters, and the icteric index was 7.5 units. X-rays of the skull and lungs were negative. The urine contained 0.15 mg of arsenic per liter and arsenic was found in the urine of both parents, but the source was not discovered.

The treatment consisted of the use of sodium thiosulfate and thyroid extract. The blood count soon returned to normal and arsenic disappeared from the urine. She was seen in the Vascular Clinic of the New York Post-Graduate Hospital at the age of 15 and was still complaining of stiffness of hands, arms, and legs. Mecholyl iontophoresis and pancreatic tissue extract (Depropanex) injections were started and for eight months she improved. Despite continued therapy, however, ulcers over the proximal interphalangeal

joints of both hands developed and the joints gradually became stiffer. At the age of 16, x-ray studies of the hands showed no significant pathology, but x-rays one year later showed narrowing of the joint spaces with capsular distention and generalized periarticular lime-salt deficiency. About this time she had a few attacks of diarrhea, each lasting two to three days and consisting of eight to seventeen watery stools a day. Occasionally, a rise in temperature was noted with these episodes. In the gastrointestinal clinic free hydrochloric acid was found in the gastric contents, and examination of the feces showed the presence of *Endolimax nana*. At the age of 17 she was admitted to the hospital on three occasions for manipulation of the fingers under anesthesia. The basal metabolism at this time was 2 per cent below the average normal. One year before the final admission she attended the clinic of another hospital for two months. Here a tachycardia was noted and the basal metabolism was 27 per cent above the average normal. X-ray studies revealed calcium deposits in the soft tissues of the left arm and the lower left femur, with decalcification of the shafts of the long bones. The blood pressure was 130/80 mm Hg. A hemithyroidectomy and parathyroidectomy were done in that institution and, on microscopic examination, revealed normal histologic structures. Preoperatively, the serum phosphorus was 3.9 mg per hundred cubic centimeters, and postoperatively it was 4.9 mg per hundred cubic centimeters with a serum calcium of 11.8 mg per hundred cubic centimeters. She soon returned to the New York Post-Graduate Hospital where mecholyl treatments were resumed. Her basal metabolism, serum calcium, and serum phosphorus were within normal limits at this time. Preceding the final admission she began to have episodes of dizziness and was seen in the cardiac clinic where her blood pressure was found to be elevated (160 mm Hg systolic). The electrocardiogram was normal except for tachycardia and a right axis deviation. The day before admission the blood pressure was recorded as 230/150 mm Hg. Of interest was

the presence of hypertension in both parents

Physical examination at the time of admission showed a poorly developed young woman with a masklike expression. The skin over the bridge of the nose and face was tightly drawn, smooth, shiny, and hard. A similar change was noted in the skin covering the hands, wrists, and upper thorax. A yellowish brown pigmentation was uniformly scattered over the skin of the entire body from the neck down. Examination of the fundi revealed moderately tortuous vessels with pallor of the disks. There was some limitation of excursion of the mandible due to the tension of the skin. A thyroidectomy scar was present in the neck. The lungs were clear. There was no cardiac enlargement. The rhythm was regular at a rate of 104 per minute. No murmurs were heard but A_2 was accentuated. The blood pressure was 220/152 mm Hg. The abdomen was not unusual. Examination of the extremities showed the fingers of both hands contracted at the proximal interphalangeal joints to 45 degrees with no extension beyond that position. The skin of the fingers was tightly drawn, transparent, and shiny. There was no limitation of motion in the wrist, but the patient was able to flex the knees to 45 degrees. Reflexes were normal.

Urinalysis on numerous occasions showed a specific gravity of 1.020 with 1 plus protein and, occasionally, a few granular and hyaline casts. Blood chemical studies, including uric acid, creatinine, calcium, phosphorus, and phosphatase, were within normal limits. The urea nitrogen was 16.5 mg per hundred cubic centimeters. The total serum proteins were 8.2 mg per hundred cubic centimeters, with albumin 3.9 and globulin 4.3 making an A/G ratio of 0.9. A glucose tolerance test was normal. The Wassermann reaction was negative.

The day after admission the patient had an episode of dizziness lasting ten minutes and vomited a large amount of greenish fluid. The ophthalmologic consultant reported bilateral papilledema, particularly of the right eye, arteriosclerosis, and edema of the retina. The blood pressure remained elevated (200/152) even after a test dose of 9 grains of sodium amytal. Five days after admission the patient developed a sore throat and later in the day complained of pain in the left anterior part of the chest. Examination revealed signs of consolidation in the lower lobe of the left lung, which was confirmed by x-

rays. The leukocytes rose to 21,500 with 82 per cent neutrophils. Despite a rapid respiratory rate and a slight cyanosis, the temperature remained about 100 F (38 C). Sulfapyridine therapy was instituted, but the patient failed to respond and died on the tenth hospital day.

Discussion

DR MAURICE BRUGER. A review of the history reveals some rather important leads. As you recall, about six years ago the possibility of chronic arsenic poisoning was entertained. Scleroderma was then noted for the first time, and during the several years that followed therapy was directed particularly toward treatment of the scleroderma. During the present admission, several additional findings were present. The patient had a marked systolic and diastolic hypertension, accentuation of the second aortic sound, tachycardia, pigmentation of the skin, and papilledema. Laboratory studies revealed proteinuria, cylindruria, and evidence of impairment of renal function. Unfortunately, the blood chemistry was not repeated before death occurred, so it is impossible to state with what rapidity renal insufficiency advanced. With the development of the pulmonary complications, a leukocytosis and secondary anemia occurred. Death was probably due to lobar pneumonia.

Now, with regard to the history of arsenic poisoning, in 1936 Moench¹ of Cornell published the case record of this patient as one of chronic arsenic poisoning associated with profound anemia and scleroderma. The patient's urine at that time contained 0.15 mg of arsenic per liter and, following treatment with sodium thiosulfate, a prompt and striking improvement occurred in the blood picture. Of course, it is conceivable that the patient had arsenic poisoning, but the amount of this metal found in the urine and the clinical response to thiosulfate certainly do not prove the point. A normal individual may excrete as much as 0.8 mg of arsenic per day depending on the type of diet consumed.² Moreover, recent work in this hospital has shown that sodium thiosulfate does not mobilize arsenic from body stores for urinary elimination.³ The presence of scleroderma at the

¹ Moench, L. M. *New York State J. Med.* 36: 1029 (July 15) 1936.

² Matthei, M. R., and Weisman, D. *Am. J. M. Sc.* 193: 413 (1937).

³ Matthei, M. R., Baxt, H., and Byrne, J. M. *Arch. Dermat. & Syph.* 42: 399 (1940).

tune the diagnosis of chronic arsenic poisoning was made, however, is in favor of the latter diagnosis, since the two disorders have been associated according to some workers.

The relation between scleroderma and Raynaud's syndrome is of more than casual interest. The peripheral vasospastic phenomena characteristic of Raynaud's syndrome may precede the scleroderma or follow it. Some authors⁴ feel an underlying parathyroid dysfunction accounts for both diseases, and I believe it must have been this concept that led to the parathyroidectomy in 1940. A thyroidectomy was done simultaneously, presumably to combat the hyperthyroid manifestations. The development of pigmentation and ulceration of the skin, arthritis and arthralgia, and decalcification of bone and calcium deposits in soft tissues are not uncommon in Raynaud's syndrome and scleroderma. The etiology of the diarrhea, however, is more puzzling, and it is problematic as to the part played by the nonpathogenic *Endolimax nana* in this complication.

The advent of a new train of symptoms—dyspnea, vertigo, and fatigue—in the past six months is of importance in evaluating the course of this disease. Physical and laboratory examinations during her last hospital admission revealed marked hypertension, retinal arteriosclerosis, edema of the retina, papilledema, proteinuria, cylindruria, and slight nitrogen retention. That some underlying diffuse vascular disease may account for this picture is further substantiated by the onset of acute cerebral and gastrointestinal manifestations. The history of scleroderma and Raynaud's syndrome strongly supports such a contention.

Assuming for a moment that a diffuse vascular disease involving particularly the smaller arteries and arterioles of the body is the basic disorder in this patient, can it be classified into a recognized subgroup? This, however, is extremely difficult, since the problem of generalized arterial and arteriolar disease is in a state of flux. Clinicians and pathologists recognize diffuse vascular disease in lupus erythematosus with or without the Libman-Sachs syndrome, in dermatomyositis, and in scleroderma. Periarteritis nodosa is a closely associated lesion. Better known forms, at least from an etiologic standpoint, are the generalized arteriosclerosis of benign hypertension and the necrotizing arteriolitis of malignant hypertension. As recent as March,

1941, Katzenstein and Murphy⁵ described a case of diffuse vascular disease (sclerosis of the small arteries without thrombosis) in a 22-year-old woman, the cause of which was entirely unknown. Clinically, the disease in this patient resembled bilateral renal cortical necrosis.

From the available clinical and laboratory evidence, I shall go no further than to state that this patient probably had a generalized vascular disease, the classification of which I should rather leave to Dr. Richter. I may venture to add, however, that the lesion may be the type generally found in patients with scleroderma.

Dr. Bruger's Diagnosis

Scleroderma

Generalized arterial and arteriolar disease.

Lobar pneumonia

DR. A. WILBUR DURYEE: I do not believe any patient was ever more completely studied in our Vascular Clinic. The acute change in her condition in the terminal state was an amazing thing. In scleroderma we are dealing first with some vascular lesion, and we know that many cases of scleroderma have manifestations in other organs such as the lung, spleen, and kidneys. But why this girl after five to six years of progression should suddenly complain of the symptoms of renal involvement is extremely interesting. What precipitated this change is hard to explain. Going back to the question of arsenic poisoning, the only evidence we have as to the cause is that she ate a great many berries that had been sprayed. The main treatment was the elimination of the berries from her diet. I have not seen the slides, but I will make a guess that the lesions seen in the kidneys, although she died a pneumonic death, were due to generalized vascular disease.

DR. CARL H. GREENE: I doubt if she had any primary disturbance of the parathyroid. Why was she operated on?

DR. DURYEE: She had heard about this operation and, being unsatisfied with our decision, she was determined to have it done. Several surgeons had reported encouraging results after parathyroidectomy, but we have failed to see persistently good results. Occasionally, there does appear to be improvement for a few months, but relapse has occurred in most cases that we have seen.

⁴ Bernheim, A. R. and Garlock, J. H. *Ann. Surg.* 101: 1012 (1933).

⁵ Katzenstein, R. and Murphy, J. P. *Arch. Int. Med.* 67: 379 (1941).

Pathologic Diagnoses

DR MAURICE N RICHTER The joints of the hands could not be examined at autopsy. The left knee joint showed no changes resembling chronic arthritis. Most of the organs showed little of interest in the gross examination. There was a comparatively mild pneumonic lesion and several organs were congested. The kidneys were red and had markedly granular surfaces. The heart was slightly enlarged, and there was an area of thickening in the endocardium beneath the posterior cusp of the mitral valve.

Microscopic examination of sections of the skin showed varying degrees of thickening and condensation of the collagenous connective tissue, with a change in the staining characteristic of the latter. The collagen was somewhat more basophilic than usual, and this change was noted in several of the organs.

The most important lesion, and one that was also found in several different organs, was a lesion of the blood vessels, especially the small and medium-sized arteries. This lesion was seen to best advantage in the arteries of the gallbladder but appeared also in the kidney and ovary. It consisted of an acute inflammatory reaction in the wall, sometimes involving the intima, sometimes the adventitia. The internal elastica was fairly well preserved. With Gram's stain there were strands that retained the dye in the walls of the involved arteries. This did not always have the appearance of fibrin.

In addition to the changes mentioned, there were lesions of arteriosclerosis present in the kidneys. Similar changes were seen in the arterioles of the spleen, pancreas, perirenal fat, ovary, and submucosa of the in-

testine. In the spleen the lesion was marked.

The thyroid gland was in the colloid stage and was similar microscopically to that removed surgically a year ago.

A few small foci of necrosis were seen in the myocardium. In the rectus abdominis there were a few areas with altered staining of the connective tissues and nuclei of sheath cells of atrophied muscle fibers.

It seems likely that in this case we are dealing with a diffuse arteritis associated with scleroderma, that arteritis in the kidney led to hypertension, and that there developed, subsequently, generalized arteriosclerosis as is commonly found associated with hypertension.

Anatomic Diagnoses

Scleroderma

Ankylosis of fingers

Acute arteritis of gallbladder, kidney, and ovary

Hypertension, clinical

Generalized arteriolonecrosis

Arteriosclerotic atrophy of kidneys

Cardiac hypertrophy

Lobular pneumonia

DR BENJAMIN SILBERG What was the character of the lesion on the mitral valve?

DR RICHTER The lesion was an area of endocardial thickening below the mitral valve, presumably the result of a previous mitral endocarditis.

OUT OF THE BLACK BAG

The doctor had two children who were acknowledged the prettiest in the district.

While out walking one day, they passed two small boys. One lived in the village and the other was a visitor.

"I say," said the latter, "who are those little girls?"

"They are the doctor's children," replied the village boy. "He always keeps the best for himself."

—*Canadian Doctor*

SAFETY FIRST

The doctor had advertised for a secretary and among the applicants was a young lady of undiminished beauty and graceful figure.

"And where were you employed previously?"

"In a doll factory," was the reply.

"And what were your duties?"

"Making eyes."

"Well," said the doctor, "you're engaged, but forget your old job when my wife is around."

—*Exchange*

ADVICE TO MEDICAL STUDENTS

"Be true to yourselves, your patients, and your profession, and some day you will be proud

of your profession and your profession will be proud of you."

DR JEAN OLIVER, *President*

DR JOHN M PEARCE, *Secretary*

Histologic Changes Produced in Squamous-Cell Epithelioma of the Mouth and Oropharynx by Fractionated External Irradiation Dr John W Hall *(by invitation)* and Dr Milton Friedman *(by invitation)*

A detailed histologic study was made of tissue obtained from 28 patients with squamous-cell epithelioma of the mouth and oropharynx who had been treated with the protracted fractionated method of irradiation (Coutard technic). An average of five biopsy specimens, including one taken before treatment, was secured from each patient.

The histologic changes observed in the tumor tissue following irradiation were of three types (1) acute cell death, (2) formation of giant-sized tumor cells, (3) irradiation keratogenesis, i.e., the acceleration of the keratinization process in keratinizing and keratinized cells.

The process of acute cell death, occurring in radiosensitive cells, was most marked during the first seven days after the beginning of treatment, although evidences of this process were still visible up to the fourteenth day. While emphasis has been given to the process of tumor cell degeneration by the formation of giant-sized cells, nevertheless, acute cell death accounts for the destruction of a plurality of cells. The most prominent histologic evidence of degeneration seen in acute cell death is karyolysis, although to a less extent one sees pyknosis of the nuclei and slight swelling of the cytoplasm.

The formation of giant-sized tumor cells occurred if the cells were less radiosensitive. There were two types of giant-sized cells, depending on the part of the cell—cytoplasm or nucleus—primarily affected. When the irradiation primarily affected the cytoplasm, there resulted cells measuring up to 180 micra in greatest diameter, showing marked swelling and vacuolization of the cytoplasm. When the nucleus was primarily affected, there resulted giant-sized tumor cells representing mutation forms produced either by changes in the structure of the chromosomes

or by disturbance in cell division. These nuclear changes were of two types: either giant-sized nuclei varying markedly in shape and chromatism or multinucleation.

The process of radiation keratogenesis was either rapid (acute) or slow. In several instances of acute keratogenesis practically all of the cells showed various degrees of keratinization by the ninth day, and biopsy material obtained at later dates showed only masses of keratin surrounded by multinucleated foreign body giant cells lying in a dense connective tissue stroma. Where the process of radiation keratogenesis was less rapid because of greater radioresistance of the cells or because of inadequate irradiation, the process of keratinization was incomplete. Radiation keratogenesis also occurred in the overlying normal epidermis or mucous membrane epithelium. While the process in these tissues was slower, requiring twenty-one to twenty-five days, desquamation finally occurred when the keratinization process involved all the cell layers, including the basal cells.

In radioresistant cells only slight swelling and vacuolization occurred. These changes seemed to be transient.

In tissues obtained from 8 of the 28 patients, squamous metaplasia of the submucous salivary gland epithelium was observed. In a few instances this process was so marked that the metaplastic epithelium itself was hyperplastic.

Discussion

DR JEAN OLIVER: Have any experiments been done which combine colchicine treatment and x-ray therapy, colchicine arresting mitotic figures to a certain point, letting them heap up, the x-ray thereby affecting many more mitotic figures than would normally happen?

DR JOHN W HALL Several experiments have been reported concerning the combined effect of colchicine and x-ray therapy upon animal tumors. Some of these experiments indicate that colchicine is either ineffective in enhancing the action of x-rays on tumors or does not strikingly increase the destructive effect of the x-ray therapy.

DR PAUL KLEMPERER In the tumors that showed the cytoplasmic changes, the keratinization, and the giant forms, did you pay attention to whether mitoses were found in such cells? Do these cytoplasmic changes indicate that the process of degeneration is irreversible?

DR HALL We have noted a few abnormal mitotic figures in the giant-sized tumor cells. Their number appears to be dependent upon the time when the biopsy specimen was removed. During the first week there was an increase in the number of mitotic figures and abnormal forms began to appear. Thereafter the mitotic figures became almost exclusively abnormal in form, gradually diminished in number, and in some instances disappeared entirely. We are of the opinion that the giant-sized tumor cells are degenerating forms and will eventually die out because of failure to multiply. Further evidence substantiating this belief is the fact that, if the neoplasm recurs, the histologic appearance in the recur-

rence is that of the original tumor before irradiation treatment.

DR ALFRED ANGRIST I wonder whether the factor of control of the nature of the biopsy was employed. So often we get such variable pictures, and dependence alone on punch biopsies has always been a problem in attempting to evaluate tumors.

I wonder whether in these extensive studies any thought, however tenuous, as to any biologic factors can be advanced for explaining these changes. Have the authors anything to contribute in this regard?

DR HALL I am not sure that I understand the nature of the question, but as far as biopsies are concerned we realize the possibility of making mistakes. However, we have attempted to overcome this by taking pieces of tissue from various areas of the tumor, having taken as many as one to four pieces of tumor tissue from different areas, with an average of two. For instance, if the tumor began in the tonsillar pillar region and extended to the tongue, we took sections of the tonsillar pillar region and also of the tongue. The biopsy material I think was larger than is usually taken. I would say each individual piece averaged 8 by 6 mm. Occasionally, pieces were as large as 1.2 by 1 cm., so that many times punch biopsy was not used but the tissue was removed by means of a scalpel.

Tumors of the Eye Dr. A. B. Reese *(by invitation)*

Benign melanomas of the choroid are fairly common. They are frequently overlooked clinically. Malignant melanomas may arise from these benign lesions. The clinical and histologic characteristics of these tumors were discussed. The only other place where the type cell is seen, from which the melanoma of the uveal tract arises, is in the mongolian spot and the blue nevus. The malignant melanoma arising in the choroid, therefore, is not comparable to the malignant melanoma arising elsewhere over the body. The mortality for this tumor of the uvea after enucleation was about 50 per cent in a series of 350 cases of the Army Medical Museum after a five-year follow-up. The argyrophil fiber content seems to be a good criterion of the degree of malignancy. Similar benign and malignant melanomas are also encountered in the ciliary body and iris but much less frequently.

The retinoblastoma (retinal gloma) occurs in children, 25 per cent are bilateral by multiple origin and not by extension. Calcium deposition is common, and the tumor tends to invade the optic nerve. The tumor proves fatal

by direct extension to the brain via the optic nerve or by distal metastases to the bones. The mortality after enucleation was 52 per cent in a series of 95 cases from the Army Medical Museum after a five-year follow-up.

Metastatic carcinoma to the uveal tract is more frequently primary in the breast, thyroid gland, lungs, and stomach. It is not uncommon to have a metastatic carcinoma manifest itself in the eye before the primary site is diagnosed.

Among the rarer intraocular tumors are benign adenoma of the ciliary body, hemangioma of the choroid, and neurofibroma of the uvea.

The tumors of the lids and orbit, in the order of their frequency, were mentioned.

Stress was placed upon the importance of precancerous melanosis of the conjunctiva as the forerunner of malignant melanoma of the conjunctiva. This appears as a diffuse, flat pigmentation in middle-aged individuals. After several years it becomes malignant and has the same unfortunate prognosis as malignant melanoma in general, unless a radical

exenteration of the orbit is done early in the disease

Congenital nevi of the conjunctiva, comparable to the neurogenic nevi of the skin, are common and do not lead to malignant melanomas

Slides illustrating the various types of tumors and their characteristics were shown

Discussion

DR ANDREA SACCONI About ten years ago a patient 70 years of age was treated in the Metropolitan Hospital. The eye was enucleated because there was a neoplastic mass in the internal region of the cornea, invading the sclera. Histologic examination showed a squamous-cell carcinoma. The slide was also examined by Dr Ewing. After three weeks the patient died of hypostatic pneumonia. A most careful examination at autopsy failed to show any other focus for the carcinoma, so we concluded that the squamous-cell tumor was a primary carcinoma of the cornea.

DR JEAN OLIVER I was going to ask Dr Reese about tumors of the cornea, I notice he did not mention them

DR A. B. REESE We practically never see tumors primary in the cornea. Bowen's disease or an intraepithelial epithelioma is sometimes encountered. I have seen 2 regular epitheliomas of the cornea, both of which developed as a later complication in the base of a corneal ulcer. One of the patients had xeroderma pigmentosum. Usually, tumors are primary at the limbus and spread secondarily onto the cornea. Such tumors are sometimes referred to incorrectly as a corneal tumor.

DR ALFRED ANGRIST I wonder whether your experience with these tumors of the eye in the melanoma group has ever offered any information to explain the known tendency for long intervals to elapse before metastases become manifest in this group. As a corollary to that question, why is a metastatic focus so often so extensive and occasionally entirely limited to the liver with no other area involved? I have had several cases of that type. Is there any explanation for it?

DR REESE It is amazing that a malignant melanoma of the uveal tract may apparently manifest itself in the liver even twenty-five years after an enucleation. I have no explanation.

POLITICS THREATENING HEALTH

The politicians are trying to meddle with the people's health and with the practice of medicine, so why shouldn't the doctor take a hand in political matters? No group outside the medical profession, says a writer in *Radiology*, "is competent to guide the policies of the government in matters of health. It is the responsibility of the medical profession to provide this guidance. Under our system of government there is one way, and only one way, that such responsibility can be exercised—and that is through political effort."

"Two points must be understood if the political effort of individual doctors and medical organizations is going to have any effect upon the policies of the government. To appreciate them fully, it is going to be necessary that some firmly settled illusions be discarded. First, local politics is much more important than national

politics. Second, the primary is vastly more important than the general election. Any citizen can exert a great deal more influence upon the political trends of the national government by quietly interesting himself in the politics of his own neighborhood precinct than he can by writing brilliant letters to his congressman. Furthermore, he will find that the time to convince a politician regarding any fundamental issue is before the election and not afterward.

"These are stirring times in America—times during which the cloak of 'national defense' can be used to usher in radical innovations in the function of the national government. Now is the time for all good doctors to come to the aid of their nation. They can aid their country and protect the interests of the people by once more occupying a prominent place in the civic and political life of the community."

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF ORAL DIAGNOSIS

The Eighth Annual Congress of the American Association for the Advancement of Oral Diagnosis will be held in New York City on November 13 and 14 at The New York Academy of Medicine.

The papers, discussions, and exhibits will cover oral diagnosis, with special attention given to

the basic sciences as related to oral diagnosis.

Members of the medical and dental professions in the United States and countries of the Western Hemisphere are cordially invited to attend. Programs may be obtained by communicating with the secretary, Dr H. Justin Ross, 515 Madison Avenue, New York City, New York.

Thirty-Fifth Annual Meeting of the District Branches of the Medical Society of the State of New York

PROGRAM

Third District Branch

Tuesday, September 30, 1941
Saulpaugh Hotel
Catskill, New York

Morning Session—10 00 A.M.

General program of activities of the State Society and their relations to the county societies, as presented by the officers of the State Society

Mahlon H. Atkinson, M.D., Catskill, *president of the Third District Branch, presiding*

Samuel J. Kopetzky, M.D., New York City, *president of the Medical Society of the State of New York*

Advantages of Organization

Peter Irving, M.D., New York City, *secretary and general manager of the State Society*

How the general activities of the Society are put into motion. The council and committee organization. Duties. *New York State Journal of Medicine Medical Directory of New York, New Jersey and Connecticut*

Edward T. Wentworth, M.D., Rochester, *chairman of the Finance Committee*

John L. Bauer, M.D., Brooklyn, *chairman of the Committee on Legislation*

Joseph S. Lawrence, M.D., Albany, *executive officer*

Nothing is more important to medical men than legislation that affects their patients or themselves. Hence, the chairman of the legislative committee must be one who will give all necessary time to the job. He and his associates on the committee must cultivate the friendship of the local boss, the members of their local bar association, and of the legislators. Keep the legislators informed on the attitude of organized medicine on bills under consideration. Keep Dr. Lawrence informed on the attitude of the legislators as observed at their homes.

Augustus J. Hambrook, M.D., Troy, *chairman of the Committee on Public Relations and Economics*

Thoughtful consideration of the relations with other agencies, official and unofficial, is most essential. Conferences with representatives of state departments for adjustment of programs are frequent. Occasionally

our advice is sought by representatives of Federal agencies. Many demands have been made upon this committee to help interpret and administer the Welfare Law. Leadership in all community programs that relate to public health or the practice of medicine should be the constructive objective of every county society.

O. W. H. Mitchell, M.D., Syracuse, *chairman of the Committee on Public Health and Education*

Dr. Mitchell will briefly present the program of this committee for the coming year. The numerous activities require the attention of several subcommittees, and their organization and functions will be described. Postgraduate instruction will be especially considered and a copy of the recently revised *Course Outline Book* will be available for every county society desiring one.

Floyd S. Winslow, M.D., Rochester, *chairman of the Committee on Medical Publicity*

Mr. Dwight Anderson, New York City, *director of the Public Relations Bureau*

The aim of the committee is to fulfill the following purpose expressed in the Society's Constitution: "To enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the State." Principal means used are newspaper releases, printed matter for direct distribution, radio, and service bulletins to physicians and laymen.

Clarence G. Bandler, M.D., New York City, *chairman of the Committee on Workmen's Compensation*

David J. Kaliski, M.D., New York City, *director of the Workmen's Compensation Bureau*

Recent amendments and court decisions involving the Compensation Law, and the rights of physicians and responsibilities of the compensation committees.

Clarence G. Bandler, M.D., New York City, *chairman of the Committee on Malpractice, Defense and Insurance*

Our counsel is the most expert in this line.

of legal activity and defense has been more than adequate. The background for the majority of malpractice actions has been loose, unwarranted, and frequently thoughtless criticism by fellow members of their confreres. This phase of medical practice should be vigorously attacked in every community in order to set up an effective barrier against unfortunate and unjust claims.

Mr. Lorenz J. Brosnan, New York City, *Counsel for the Medical Society of the State of New York*

1 00 P M Luncheon and Introduction of Guests

Afternoon Session—2 30 P M

Group Conferences

The physicians will break up into different groups so that the chairmen of committees of the seven component county societies can meet in conference with the chairmen of the corresponding council committees.

Fourth District Branch

Friday and Saturday, September 26 and 27, 1941

Lake Placid Club

Lake Placid, New York

Friday, September 26 2 00 P M Daylight Saving Time

Symposium on Tuberculosis

"Tuberculosis Control and Case Finding in a Rural Community"

Richard Nauen, M D, Ray Brook, N Y, *senior tuberculosis physician, Outpatient Department, Ray Brook State Hospital*

A brief exposition of the principles underlying case-finding and the control of tuberculosis, and their practical application in the Ray Brook Hospital District, with a short summary of the results.

"Tuberculosis in Industry"

Beverly L. Vosburgh, M D, Schenectady, *medical director, General Electric Company*

This paper will discuss tuberculosis and related medical problems of industry.

"Management of Pulmonary Tuberculosis"

Fred H. Heise, M D, Trudeau, N Y, *medical director, Trudeau Sanatorium*

Pulmonary tuberculosis may exist without symptoms or physical signs and may exist where there is a known disability from another cause. Painstaking care in the education of the patient in the whys and wherefores of treatment is essential. Tuberculosis is a chronic disease and much of the treatment must be carried out by the patient himself.

"Surgery in Pulmonary Tuberculosis"

Warner Woodruff, M D, Saranac Lake, N Y

The judicious use of surgery in suitable cases is of great value in the treatment of pulmonary tuberculosis. The indications for the various types of procedures will be discussed with illustrations.

Saturday, September 27 9 30 A M

Symposium on War Surgery

"Blood Studies in Shock as a Guide to Therapy" [with motion pictures on (a) shock and (b) blood and plasma]

John Scudder, M D, New York City, *Department of Surgery, College of Physicians and Surgeons, Columbia University*

Certain tests, of more value than blood pressure determination in the anticipation of shock, measure loss of fluid from the blood—hemococoncentration (1) specific gravity of peripheral blood, (2) cell volume as determined by the hematocrit, (3) specific gravity of the plasma, (4) estimation of total plasma proteins. These tests give objective evidence of whether more fluid should be given or whether fluid therapy should be stopped.

"War Wounds of the Extremities with and Without Involvement of the Bony Structures"

Lieut.-Col. George A. Koenig, M D, Fort Jay, N Y, *clinical professor of surgery, New York University*

The paper will cover the methods of treatment in the first World War and show the development of the improved methods used in the present war, especially in regard to prophylaxis, transportation, chemotherapy, immobilization of fracture cases and evacuation.

"The Problem of Burns in Warfare"

John M. Converse, M D, New York City, *clinical assistant, Plastic Surgery, St. Luke's Hospital*

Entertainment

The Women's Auxiliary of Essex County has planned a ride up Whiteface for Friday afternoon for the ladies.

At the conclusion of the Saturday morning program a picnic lunch will be served to all attending the meeting, on Moose Island in Lake Placid. The autumn colors should be beautiful at this time.

Evening Session—7 00 P M

Dinner

Address by Samuel J. Kopetzky, M D, New York City, *president, Medical Society of the State of New York*

Entertainment

The Schenectady County Medical Society Orchestra and an outstanding speaker

DISTRICT BRANCH MEETINGS

1879

Eighth District Branch

(This is its thirty-sixth annual meeting)

Thursday, October 2, 1941

Hotel Jamestown
Jamestown, New York

Morning Session—9 30 A.M.

Motion pictures with sound accompaniment
These films have been lent by Mead Johnson & Company and prepared by the authors as noted below

1 "Appendicitis"

Joseph Brennemann, M.D., Chicago, emeritus professor of pediatrics, Rush Medical School, chief of staff, Children's Memorial Hospital, editor, Brennemann System of Pediatrics

2 "Pneumonia"

Isaac Arthur Abt, M.D., Chicago, professor of pediatrics, Northwestern Medical School, and chief of service, Sarah Morris Hospital for Children

10 30 A.M.—Scientific Papers

"The Injection Treatment of Varicose Veins"

Herman E. Pearse, M.D., assistant professor of Surgery, University of Rochester School of Medicine

The speaker is well qualified to discuss the various aspects of this practical subject from both the standpoint of indications and technique as adapted to the different types of cases

"Amputations Through the Hand"

J. Harold Couch, M.A., F.R.C.S., Department of Surgery, University of Toronto

Amputations through the fingers are the most unsatisfactory amputations that surgeons perform. Many patients return demanding reamputation. This speaker has written a book on this subject and will accompany his presentation with a colored motion picture demonstrating the optimum levels to amputate in the various parts of the hand for the best functional result

"The Clinical Use of the Sulfonamide Group of Drugs"

W. Barry Wood, Jr., M.D., associate in the department of medicine and associate physician to the Johns Hopkins Hospital

The sulfonamide group of drugs will be discussed as it applies to the physician in general

practice. A list of diseases which can be helped by each drug will be given. The method of use including dosage will be outlined in detail.

12 30 P.M. Luncheon and Introduction of Guests

Afternoon Session—2 00 P.M.

Business Meeting—Election of Officers

"Critical Review of Procedures of Active and Passive Immunization"

John A. Toomey, M.D., Cleveland, chairman, National Committee of Immunization Procedures, professor of pediatrics, Western Reserve Medical School, director of the department of contagious diseases, Cleveland City Hospital

Dr. Toomey's many years of experience in research and the practical application of immunological problems have made him an authority on the subject

"Pathology of Uterine Cervix as Encountered in General Practice"

James E. King, M.D., gynecologist-in-chief, Buffalo General Hospital, professor of gynecology, University of Buffalo School of Medicine

Many conditions in women arising from cervical pathology should be recognized and treated by the general practitioner. An attempt is made to visualize some of the common pathology and to indicate how by its recognition a rational treatment may be employed

Entertainment for Ladies

All doctors' wives are invited to attend. A most interesting trip through the Furniture Exposition Building has been arranged. On the eight floors are displayed examples of the various periods of furniture design. Luncheon with the doctors has been arranged at the Hotel Jamestown.

ONE SIGN, ANYWAY

The honeymoon over, the timid bridegroom began cleaning his thick eyeglasses. "Darling," he said, "I have a confession to make. I want to tell you I am color blind!"

Answer "Yo sho am, honey chile"

—Medical World

OVERSHOT THE MARK

Patient "Well, have any of your childhood ambitions been realized doctor?"
Doctor (father of large family) "At least one of them—it was always my desire to wear long trousers, and now I believe I wear them longer than anybody else"

—The Canadian Doctor

Medical News

County News

Cortland County

A scale of medical fees for doctors caring for patients who are receiving county welfare was approved on August 6 by the board of supervisors. The county has been divided into zones where certain rates for home calls apply. A doctor in one zone answering a call in another where there is a physician will be paid the minimum for that zone.

Office calls for indigent patients will cost the county \$1, home calls within 1 mile radius of the physician nearest to the patient, \$2, calls between 1 and 8 miles, \$3, and for calls more than 8 miles, \$4. There are very few parts of the county where patients are more than 8 miles from the nearest physician and the \$4 fee will be rare.

If a patient living in one zone where there is a doctor within a mile of his home, desires a physician who has to travel 5 miles, the county will pay only \$2, the rate for 1 mile.

Greene County

Despite the efforts of the members of the Greene County Tuberculosis and Public Health Committee, and the presentation of a petition signed by the physicians of the county medical society, recommending the appropriation of the sum of \$4,059 to provide additional nursing service for the county, a motion introduced for this purpose at the regular meeting of the County Board of Supervisors on August 11 was defeated by a vote of 8 to 6.

Jefferson County

Dr. Gilbert A. Foote, aged 82, who retired from the active practice of medicine a year ago after a medical career of nearly fifty-three years, died on August 17 at his home in Dexter after an illness of only eleven days. Death was caused by angina pectoris.

Dr. Foote, one of Jefferson county's oldest physicians and one of the best known residents of Dexter, was vice president of the First National Bank of that village and had been a director of the institution for the past thirty-five years.

In addition to maintaining a private practice, Dr. Foote served as health officer of the town and village for forty-five years.

Kings County

Dr. Philip I. Nash, for many years active in the Coney Island community, was honored at a testimonial dinner on the final night of the Mardi Gras, September 13, at the Half Moon Hotel, Coney Island.

Dr. Nash, medical examiner of the District Attorney's office, was the first president of the Coney Island Chamber of Commerce and held that office for five consecutive years. During his tenure many improvements were made in the seashore community.

During the forty years he has been a practicing physician at Coney Island he has been chairman of the medical board of the Coney

Island Hospital for the past thirty-five years. He also has served in a similar capacity at Harbor Hospital in Bensonhurst for many years. He was formerly president of the Kings County Medical Society and at one time taught medicine at Long Island College Hospital. Dr. Nash also is an active member of the American College of Surgeons.

Dr. Henry Joachim, a specialist in internal medicine, who was president of the Kings County Medical Society in 1936, died on August 13 in his apartment in the Waldorf-Astoria Tower after a long illness. He was 58 years old.

Monroe County

Anticipating a possible shortage of doctors for military and civilian defense needs, University of Rochester's School of Medicine and Dentistry announced recently that it was admitting sixty-five new students, the largest entering class in its history.

Twenty-two colleges and seventeen states are represented in the group, chosen from more than 800 applicants.

Nassau County

Long Beach's physicians are now taking an active part in the nation-wide defense drive, it is revealed with the announcement that the county medical society has appointed a Medical Defense Corps for the district embracing the islands of Long Beach and Island Park.

Dr. J. J. Blinn, chairman of the local unit, says that the fifteen local member physicians are being divided into three sections. One division will serve as the hospital staff, while another will be detailed to the scene of disaster. The third will be stationed at their offices, pending assignment to either the hospital or emergency scene.

The corps will cooperate entirely with other civilian and military groups under the defense setup, it was stated.

Twenty-two South Shore banks promoted a "Pay Your Doctor Month" in August through a series of cooperative advertisements appearing each Friday during the month.

The "pay your doctor" plan, available for the settlement of both doctors' and dentists' bills, is to obtain a personal loan from a bank, pay the bill in full and then pay off the loan conveniently in small weekly or monthly payments.

The program had the approval of the public relations committees of the Nassau County Medical Society and the Nassau County Dental Society. A similar program has proved popular in New York City, where doctors and dentists having thousands of dollars due them in uncollected bills have arranged for their patients to pay off these amounts in small payments to banks.

The plan is reported to be popular with both doctors and dentists and their patients.

New York County

The county society's Special Committee on Child Welfare in the past year has considered several practical methods to protect children against disease, says the *Medical Week*. A very important one is the examination of domestic servants. Physical examination before employment, including x-ray of the chest, would uncover many cases of tuberculosis, and prevent its spread to previously uninfected households.

Periodic tuberculin tests would also help to eliminate phthisis in children. A routine tuberculin test on every child examined in the clinics or admitted to the wards would provide an excellent vantage point for a continuous drive against tuberculosis in childhood.

The care of cardiopathic children today leaves much to be desired. It is a sad reflection on the prevailing sense of values that, with money spent like water on all kinds of nonessential projects, there are not enough hospital beds to house the great number of children crippled by rheumatic fever. Weapons of war are important—but it must not be forgotten that rheumatic fever is almost as destructive of life and hope as Hitler. Proper care of these children would prevent many deaths in middle age, when man should be at the height of his productivity.

Even more than at other ages, in childhood the goal should be prevention and early detection of diseases. For this reason the county society's Special Committee on Child Welfare has tried to supply physicians for the examination of high school students. Experience has proved, however, that this task is too big for voluntary contributions of time. The medical men who volunteered were called upon to make too many examinations at each session for satisfactory performance. This is a service which self-supporting families should provide for their own children and the city for the medically indigent.

It is obviously impossible, in a brief space to touch on all the questions related to child welfare in a community the size of ours. Undaunted by their number and complexity, the county society's Special Committee has endeavored "to investigate as many problems as possible in this field." Many medical and social welfare

agencies will testify that it has done yeoman's service in pursuit of this aim.

Oneida County

The annual outing of the Syracuse Academy of Medicine and the Utica Academy of Medicine will be held at the Teugega Golf Club, Rome, Thursday, September 18.

The Syracuse Academy will act as host and furnish the program—golf followed by dinner.

St. Lawrence County

The county society held its last social meeting of the year at the Gouverneur Country club on August 28. The staff of the VanDuzee hospital were hosts and a program of golf and cards was scheduled for the afternoon.

Steuben County

Following a week's illness at Bath Hospital, Dr. Deyo Palmer Mathewson, aged 72, died on August 19. He had been in feeble health for two years, but his last illness was of but a few days' duration.

He had been active in practice in Steuben County about fifty years.

Dr. Mathewson was several years superintendent of the former county institution, the Pleasant Valley Sanitarium for tuberculosis patients at Bath, resigning because of ill health six years ago. He was a former president of the county medical society and had served as health officer in Bath town and village.

Wayne County

The Wayne County Medical Society held its August meeting at the Wayne County Health Camp on Lake Ontario, Town of Sodus. About sixty doctors and guests attended.

Dinner was served in the main dining room by the regular camp officers. Before dinner there was an inspection. There were ninety-two children present when the visit was made, and Dr. Ralph Sheldon, committee president, explained that there were ninety-six children there the first month. Children have gained from one to eight pounds in weight.

Operation of the camp is in the hands of six counsellors, a trained nurse, and the director Dr. Sheldon, besides being president, serves as medical supervisor.

Deaths of New York State Physicians

Name	Age	Medical School	Date of Death	Residence

Dr. Henry Joachim, a specialist in internal medicine, who was president of the Kings County Medical Society in 1936, died on August 18 in his apartment in the Waldorf-Astoria Towers after a long illness. He was 58 years old.

Monroe County

Anticipating a possible shortage of doctors for military and civilian defense needs, University of Rochester's School of Medicine and Dentistry announced recently that it was admitting sixty-five new students, the largest entering class in its history.

Twenty-two colleges and seventeen states are represented in the group, chosen from more than 800 applicants.

Nassau County

Long Beach's physicians are now taking an active part in the nation-wide defense drive, it is revealed with the announcement that the county medical society has appointed a Medical Defense Corps for the district embracing the islands of Long Beach and Island Park.

Dr. J. J. Blinn, chairman of the local unit, says that the fifteen local member physicians are being divided into three sections. One division will serve as the hospital staff, while another will be detailed to the scene of disaster. The third will be stationed at their offices, pending assignment to either the hospital or emergency scene.

The corps will cooperate entirely with other civilian and military groups under the defense setup, it was stated.

Twenty-two South Shore banks promoted a "Pay Your Doctor Month" in August through a series of cooperative advertisements appearing each Friday during the month.

The "pay your doctor" plan, available for the settlement of both doctors' and dentists' bills, is to obtain a personal loan from a bank, pay the bill in full and then pay off the loan conveniently in small weekly or monthly payments.

The program had the approval of the public relations committees of the Nassau County Medical Society and the Nassau County Dental Society. A similar program has proved popular in New York City, where doctors and dentists having thousands of dollars due them in uncollected bills have arranged for their patients to pay off these amounts in small payments to banks.

The plan is reported to be popular with both doctors and dentists and their patients.

Hospitals and Sanitariums

Institutions of Specialized Treatments

CREST VIEW SANITARIUM

Phone
GREENWICH
773

For Nervous, Mildly Mental, Digestive and Cardiovascular cases, and special care for **ELDERLY PATIENTS**. Quiet, refined, homelike. 25 miles from N. Y. City. Moderate rates.

F. ST. CLAIR HITCHCOCK, M.D., Director
275 NORTH MAPLE AVE., GREENWICH, CONN.

ELMCREST MANOR

A PRIVATE SANITARIUM for the individual care and treatment of nervous, mildly mental patients, toxic conditions and habit problems. Located in central Connecticut, limited to 33 selected patients.

45 Totowa Ave. **PATERSON, N. J.** Armory 4-2342

'ROUND-THE-CLOCK CARE

The longest day of the year, officially, may be that cold day in December—but to many the longest day is the twenty-four hour day of illness.

Time is an eternity for those confined to bed, and even more so when their wants are neglected. There are few ordeals more trying than long nights of waiting for someone to come to life and to the assistance of those who are too ill to help themselves. Without a doubt it is then that even the slightest irritation is magnified a hundred-fold from a knowledge that there is no vigilant person close by ready to answer the call.

Small matters of attention may be often overlooked in

planning the all-important regime for a particular patient and illness. We may forget that as a rule the sick person is a self-centered being who is seldom very considerate of the endurance of others. The sick one wants attention—wants it immediately and without reservation. And he ought to have it.

Sanitariums and Nursing Homes generally, place great importance on their provisions to provide day and night care for patients. Keeping the patient occupied during waking hours and more contented during sleeping hours to assure beneficial rest is as necessary to the efficiency of the institution as are comfortable and quiet rooms.

McKINNEY'S SANITARIUM

for **ELDERLY PEOPLE,**
CONVALESCENTS and
CHRONIC INVALIDS

105 BRUCE AVE., YONKERS, NEW YORK
YONKERS—3365

Under medical supervision tender and devoted care in an atmosphere unusually home-like. Expert dietetic and nursing service. Full cooperation with patient's personal physician.

WEST HILL

West 232nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous, mental, drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

Medical Preparedness

Emergency Medical Service for Civilian Defense

THE Medical Division of the Office of Civilian Defense has issued its first bulletin from Washington, D C The material therein is general in scope and relates to the appointment of local chiefs of Emergency Medical Service and Local Medical Advisory Councils on Civilian Defense The State Defense Council has already discussed these recommendations as they relate to New York State with Dr George Baehr, chief medical officer of the Office of Civilian Defense, who is also a member of our Preparedness Commission He is thoroughly familiar with the present State Health Defense Administrative setup, in which field a great deal of work has already been done under the chairmanship of the Hon. Lee B Mailler The place for emergency medical services centers

around hospitals where it properly belongs

The Medical Division of the Office of Civilian Defense has already established harmonious working relationships with the New York State Health Preparedness Commission, which is the official body of the State Defense Council dealing with medical and health matters relating to defense in the State of New York It is stated that the plan proposed by the Office of Civilian Defense will be worked out shortly with this official state group and through channels already established and now functioning

There should be little or no confusion or conflict in this state in applying this plan It emanates from federal sources as a master plan and bears the official stamp of approval by the President

The Doctor in the Navy

FOR every two thousand officers and men in the navy and marine corps the authorized allowance of medical officers is thirteen With the present great expansion of the navy, therefore, there has been a greatly increased need for doctors Many young doctors have joined the regular navy and the naval reserve and many of the older doctors with specialist qualifications have joined the specialist group of the reserve There are still a number of vacancies both in the regular navy and the reserve

To qualify for the regular navy doctors must be between 21 and 32 years of age and have completed at least one year of internship Medical students may take an examination sometime during their third or fourth year for an internship in one of the naval hospitals accredited for the training of interns At the end of internship they are eligible to enter the regular navy

For the medical corps of the reserve, doctors up to 50 years of age may apply If under 35 they are eligible for the general service group If between 35 and 50 they are eligible only for the specialist group The specialist group is organized into hospital units composed of eight different specialists and one dentist It is not the Navy Department's intention to call these groups to active duty except in case of general mobilization

The rank offered to doctors varies with their age, experience, and professional repute Those entering the regular navy and the general service group of the reserve are commissioned as lieutenant (junior grade) with salary of \$2,699 or \$3,158 per year, depending upon whether or not they have dependents In the specialist group the rank is either lieutenant (junior grade), lieutenant, or lieutenant commander, and the salary ranges from \$2,699 to \$4,848 The rank of lieutenant (junior grade) in the navy corresponds with that of first lieutenant in the army, lieutenant with captain, and lieutenant commander with major

The physical requirements of the navy are

rather rigid, even in the matter of height, weight, vision, hearing, and teeth The reason for this is that if an individual becomes physically disabled or if an existing disability is aggravated while on active duty in the navy he is eligible for a liberal pension or retirement pay

Medical officers in the hospital specialists units, when called to active duty, will be assigned to naval hospitals in the United States, to hospitals beyond the continental limits of the United States, or to hospital or ambulance ships and will be used in their specialty

For medical officers in the general service group and in the regular navy, active duty offers a wide variety of experience in many parts of the world and training in many specialties They may be assigned to battleships, cruisers, aircraft carriers, destroyers, or hospital ships They may be detailed for duty at naval hospitals, navy yards, naval training stations, submarine bases, naval air stations, or marine corps bases in the United States or beyond the seas They may spend most of their period of active duty at the Naval Hospital, Brooklyn, or they may serve with the marines in Iceland, Bermuda, Hawaii, or the Philippines They may be detailed to the Naval Air Station at Pensacola, Florida, or to the Submarine Base in Alaska They will have some choice as to where they go and what they do, for the navy permits officers to ask for duty they prefer and assigns them to it if practicable to do so

Junior medical officers of the regular navy and, to a lesser extent, medical officers of the general service group of the reserve, have opportunities for special training both in naval and civilian institutions

Doctors desiring information about commissions in the regular navy or naval reserve may obtain it from the District Medical Officer, Headquarters of the Third Naval District, Federal Office Building, 90 Church Street, New York City, by personal or telephone call or letter The telephone number is REctor 2-9100

CENTRAL VALLEY, Orange County, N. Y

WHAT IS NEWS?

"News! What is it?" asked a writer many years ago. Then, answering his own question, he declared, "It is the stir of life that marks the difference between a living world and a dead planet. It is the sound of civilization's machinery in motion. It is the speed gauge of progress. It is the background for all thinking, all planning and all knowledge of human affairs. When paper leaves the presses imprinted with the news, it is an inert material no longer but an active force."

Before the advent of printing and paper, exchange of reports was made chiefly by word of mouth. It was principally for this purpose that men gathered at common meeting places, formed societies for the discussion of new discoveries and common interests, and listened eagerly to the words of gossip.

While to some extent we still gather at appointed times to discuss events and new things, for the most part we obtain our information from printed pages.

We may well wonder how dwarfed the progress of medicine might have been without the medical journals

taken so much for granted today. Just as newspapers were developed as the means for transmitting an ever increasing volume of news interesting to all people, so medical journals were developed to serve the profession and keep physicians enlightened on many subjects of common interest.

The medical journal exercises many functions—advocacy, educational, fraternal and economic. The doctor of today is living in an age of medical achievement and importance that his predecessors never dreamed possible, largely because through his medical journal he can be the understudy of the best men in his profession and in his specialty.

The issue that he receives today is his reference book tomorrow. Unlike the newspaper, the contents of the medical journal, in spite of being news, lives longer because it is even more than news—it is the pattern for the practice of medicine today, tomorrow and the day after tomorrow.

TERRACE HOUSE for ALCOHOLISM

A private sanitarium offering a specific treatment for alcoholism formulated to relieve the craving for alcohol and with re-education working toward permanent abstinence. Homelike surroundings. Competent medical and nursing care. 16 miles from Buffalo.

Hospital News

Splendid New Hospital to Fight Cancer

A PROGRAM described by municipal officials and medical men as "a long step forward" in the treatment and prevention of cancer in New York City took shape in July when the city filed plans for the Florence Nightingale Hospital to be erected on a large plot in West 163rd Street.

The building, to be devoted entirely to the treatment and study of cancer, will be six stories high and cost \$2,218,500. It will house laboratory facilities and equipment far beyond anything heretofore made available by the city for handling cancer cases and for checking incipient cases of the disease.

The site, the old home of the Deaf and Dumb Institute, was donated by Presbyterian Hospital. It is between Riverside Drive and Fort Washington Avenue.

In the adjoining blocks to the north are the buildings of the Columbia Presbyterian Medical Center and in order that the Florence Nightingale Hospital may match these in appearance, the exterior of the upper five floors will be of buff brick. The lower floor and basement will be of native stone to be taken out of the site.

As designed by architects of the Bureau of Architecture of the Department of Public Works, the hospital will be of "modern functional" style, with broad window areas. It will be set diagonally on the sloping lot so that there will be a view of the Hudson River and the landscaped gardens around the building from nearly every room.

Largest Outpatient Department

The main section will have rooms for 315 patients, but most of the ground floor will be used for what was described as "perhaps the largest outpatient department for treatment of cancer in the world." Clinical cases and nonresident patients will be handled there, and elaborate facilities will be provided not only for discovering but for following up early, as well as advanced, cases.

The city will construct the building through the Department of Public Works and then will operate it through the Department of Hospitals. The staff of the new institution will be nominated by the College of Physicians and Surgeons of Columbia University.

Construction of the hospital may be delayed a year or more because of defense needs, Homer R. Seeley, acting commissioner of the Department of Public Works, said.

"There is a delay now of five to six months on steel even if you have a gilt-edge priority," he said. "The contracts are to come before the Board of Estimate in the near future, and after that four to six weeks will be needed to advertise for bids and award contracts to excavate for the foundation. There is insufficient money in this year's budget to complete the building and no provision, of course, for next year's needs yet. But the difficulty of getting steel is the big problem."

Improve Employment Conditions

AT ALL recent conventions there has been one extremely live topic, that of the difficulties present apparent in the hospital employment situation, says *Hospital Management*. Many of our employees are being called to military service, many others are attracted by higher wages being paid in industry, while some just like to change.

For the latter class, there is no apparent remedy. They are natural floaters, and it is doubtful if they are worth retaining. In any event, it is probably impossible to keep them.

Those called to military service must be replaced, and in doing so the answer as suggested is that we select new employees who are beyond the draft age.

Deferment can undoubtedly be secured for some of those who are eligible for the draft, but it is doubtful if it is desirable to seek such deferment except in case of absolute necessity. In this we must be careful to lay aside selfish considerations. We must remember that the nation needs the men and women and that we must get along without them if it is at all possible.

These two classes constitute the smallest part of our turnover, and it is to the great majority that we should devote special attention. Most employees leave hospital employ because industry offers more attractive working conditions. If we are to be successful in competing with industry, it is quite obvious that we must find out what we lack and apply the remedy.

Wages and Hours

First is the wage scale. We have habitually paid our employees a wage below that of industry, giving as our reason that we are charitable institutions offering free care to those who cannot pay for it. As a matter of fact, a great deal of our charity has been given at the expense of our employees, and they have received no credit for their contributions. This practice appears to be headed for the discard.

The second matter to be considered is that of hours of work. The eight-hour day, forty-eight-hour week is generally recognized and should be kept in mind as the desirable objective. Hospitals must be kept open at all times, and this adds to the difficulty of offering hours comparable to industry. But it can be done and it is better that we do it voluntarily than that it be forced on us by unionization. Because of conditions of work load and distribution, it is sometimes impossible to avoid broken shifts, but these are undesirable.

Old-Age Security

Security is the third of the three major factors affecting employment. *Hospital Management* has often called attention to the position of the hospital employee who has given years of faithful service to his institution and faces old age when he can no longer be productive with no provision for that age. Our employees have been excluded

from the old-age security offered by national legislation, but this is an injustice that will undoubtedly be remedied. We should work to that end, but savings and investment are a better form of old-age security. We believe that there should be an organized employees' savings and investment department in every hospital.

These are only three of the outstanding things that can be done to make employment conditions in the hospital more attractive and help forestall the threatened turnover shortage. We believe that it would be worth the time of every administrator to study conditions in his own hospital and find out how they can be improved. We mean actual study, not just moaning at the difficulties we face. Get to the employee and find out why he is thinking of leaving. This may not prevent the loss of the particular person, but it may give you a pointer that will prevent the loss of others.

Newsy Notes

Because the country's military forces are expected to make a heavy drain on trained nurses during the coming year, the Edward J. Meyer Memorial Hospital in Buffalo is planning to induct the largest class of student nurses in its history this fall. Dr. Walter S. Goodale, superintendent, announces.

The hospital is planning for a new class of 200 students in September, compared with 150 a year ago.

Workmen have been converting the old Kew Gardens Inn at 8002 Kew Gardens Road into a private hospital.

The inn closed January 1, this year, when Dr. M. A. Mason, a Bronx physician, leased the building for 35 years for approximately \$1,250,000 to set up a 240-bed institution.

Construction of the proposed \$70,000 nurses' home addition at the County Hospital in Rome is being opposed on the ground that defense building should be given priority, says the Rome *Sentinel*.

Included with the building are the proposed \$414,000 UFA gymnasium in Utica and construction of physicians' homes at Broadacres Sanatorium.

These last two are opposed by Thayer Burgess, president of the Oneida County Taxpayers' League. Supervisor George C. Wertz, Jr., Utica, is objecting to all three because of probable need of all available mechanics for construction of the Rome Air Corps Depot. The ways and means committee of the Board of Supervisors, it is learned, has assured Wertz the nurses' home addition will not be approved at this time.

The drive for the Eastern Putnam Hospital Fund has been given up on account of the national defense program, and all contributions are being returned.

Improvements

Plans for construction of a new municipal hospital for Niagara Falls have been revived by the City Council, and arrangements are being made to apply for a federal grant to defray part of the cost of the project, it is announced. City Manager W. D. Robbins, who said that the application will be sent in as soon as plans for the proposed new building are completed and a site is selected.

The application for a federal grant will be made to the Federal Works Agency of the Public Works Administration. Present plans call for a new fireproof brick building with 100 rooms, more, but details have not yet been prepared. Mr. Robbins said.

Another view is that expansion of present facilities at the Memorial Hospital is the most expedient manner in which to relieve the increasingly apparent need for more hospitalization space in Niagara Falls. P. Godfrey Savage, superintendent at Memorial states.

It would be inadvisable, Mr. Savage says, to erect a new hospital in any outlying section because of the added cost of operation such a plan would entail.

If the facilities at the Memorial Hospital were expanded through the erection of needed patient space on existing property there, the new structure could be heated by the present heating plant, and it could be operated under the same direction, he pointed out.

Mr. Savage directed attention to the Strong Memorial Hospital in Rochester, where this same procedure was followed more than fifteen years ago.

The Westfield Hospital Association is raising funds to purchase the Skinner estate and remodel it for a 26-bed community hospital.

Construction work on the long anticipated "Roslyn Park Medical Center," will be started early in September, Hubert Tannenbaum, architect of the hospital, announces.

The 50-bed institution will be built on the 6-acre park area of the former Benjamin Rosenbaum estate opposite the Roslyn railroad station.

The new building of four stories will include glass block-walled surgery and delivery rooms, private and semiprivate rooms, x-ray and therapy rooms, laboratory, diet kitchens, two sun decks, and roof gardens overlooking the Hempstead Harbor.

With the first of the new state hospital buildings at Deer Park nearly 75 per cent completed, contractors now are also busily engaged on three other structures, and work has started on relocating Commack Road, in order to keep traffic off the hospital grounds. Contracts totaling

NUMBER 19

Editorial

Medical Education and National Defense

The forty-first annual presentation of educational data by the Council on Medical Education and Hospitals of the A.M.A., as reported in the *J.A.M.A.* for August 30, 1941, is encouraging with respect to the foresight shown by most of the medical schools during the last year in preparing to meet increased demands for medical personnel.

The report points out that formal action by the Council on the question of increasing the enrollment of medical students or accelerating the output of graduates of medical schools has not been taken because of the absence of any definite information from the War Department as to the necessity for such moves. However, forty-four medical schools have increased the enrollment of the 1941 entering class by a total of 329 students. Eleven schools have made it possible for students to anticipate, during the current summer, a part of the required work of the fourth year and in three of these schools the program is required. Classes will be graduated in February or March by eight schools. Three schools will allow seniors to finish their work two months earlier and begin their internship or other work at that time, but they will graduate with the regular class in June.

"The medical curriculum has not thus far been curtailed," the report says, "although the total time involved has been shortened by cutting down vacations. Additional courses in military

medicine are being offered. The medical schools, apparently, are able to proceed without extensive revision of the curriculum and without shortening the period of residence. An accelerated program is not possible in many institutions for various reasons, including the fact that their teaching forces have been reduced for military reasons. Others would consider such a program if completion of the course could be integrated with hospital internships. The financial aspect is an important consideration both for students and for schools.

"It would appear that every effort is being made by medical educators to cooperate in the national emergency while at the same time endeavoring to insure that the education of physicians is continued at the present level and without interruption.

"It should not be necessary to argue that a continuing and undiminished supply of well-trained physicians is absolutely essential to the welfare of the nation. We cannot speed up that training beyond a certain point without lowering educational standards and degrading the quality of medical service. The present crisis demands, in fact, better qualified physicians if we are to face the future with reasonable confidence. Those who represent the medical schools are making every effort to preserve their institutions and to maintain, unimpaired, their priceless contribution to the health and welfare of the Nation."

[Continued from page 1886]

close to \$7,000,000 are now in the works, and between 400 and 600 men are employed. When completed the hospital will accommodate 10,000 patients, says the *Babylon Eagle*.

The construction now under way is only the beginning. At the State Department of Public Works, Division of Engineering, office on the grounds, it was said that close to seventy buildings will be erected before the hospital unit is complete. These buildings will include—besides the reception centers, infirmary, and permanent patients' structures—shops, warehouses, power-houses, and doctors' and staff residences.

In appearance it will be similar to the nearby Pilgrim State Hospital which also accommodates about 10,000 patients, and which has ninety buildings scattered over a large tract of land.

An addition to the De Graff Memorial Hospital in North Tonawanda, to provide 50 more beds, is contemplated, and it is hoped a federal grant of \$300,000 can be secured toward its construction.

The Shepard Relief Association Hospital at Montour Falls will construct a \$20,000 addition.

Federal authorities intend to start providing hospitalization facilities for war veterans at Saratoga Springs with a single unit, rather than construction of an extensive plant, according to a letter received by Congressman E Harold Cluett of the Twenty-ninth District from General Frank Hines, chief of the Administration of Veterans' Affairs.

The Cortland County Hospital has added two new maternity delivery rooms at a cost of over \$7,000.

The Staten Island Hospital has opened a new admitting ward for children under 12 to avoid infection, at a cost of \$3,000. During a twenty-four-hour stay in the admitting ward, the children will be under observation for contagion and, in case of infection, will be segregated.

A general hospital for Schoharie County is urged by Dr. R. D. Champlin, district health officer.

CANCER EDUCATION HELD INADEQUATE

Dr. James Ewing, consulting pathologist at Memorial Hospital for the Treatment of Cancer and Allied Diseases and dean of American pathologists, criticized on March 29 the present status of cancer education in American medical schools and urged its improvement. He made his statements in an address at the annual meeting of the board of directors of the American Society for the Control of Cancer in the Harvard Club in New York City.

According to Dr. Ewing, a recent survey made by Dr. Samuel Binkley, assistant managing director of the society, "reveals that the medical schools are generally lacking in well-organized plans for such education of students."

Conceding that cancer education in the last ten years has shown "really remarkable advances which have developed along sound lines and have brought permanent results of great value to the cancer patient," Dr. Ewing nevertheless emphasized the following summary of Dr. Binkley's survey:

"Of sixty-eight questionnaires sent to Class A medical schools there were thirty-nine replies. In all these schools the teaching of cancer, aside from pathology, was scattered through the years in the separate departments. Thirty-four schools held cancer diagnostic and treatment clinics. Attendance at these clinics was elective in 43 per cent, required, 33 per cent, and students were unable to attend because of no clinic in 18 per cent.

"Two schools had a chair of oncology. A distinct coordinated course of clinical lectures and demonstrations on cancer, exclusive of lectures in pathology, radiology, and surgery, was given in eleven schools. Twenty-eight schools felt that their students were qualified to diagnose cancer in its early stages, while eleven schools declined to make this claim. The subject of cancer should receive consideration in the State Board examinations in the opinion of fifteen schools, while seven thought not.

"A review of this report seems to justify the statement that the teaching of cancer to undergraduate students takes its chances with the interest or neglect of the heads of departments. This state of affairs is not inconsistent with a high standard of work in individual cases, but it offers no assurance that the subject is adequately covered in its essential phases."

Dr. Ewing urged that one-third of a course of 480 hours under the Department of Pathology in each medical school be devoted to instruction in the principles of neoplastic (cancer) diseases. The teaching of cancer diagnosis and treatment, he added, is the responsibility of departments of surgery and should include demonstrations of technical surgery and also of "the results of treatment pursued to the return clinic or the autopsy." He said that radiology "still remains the step-child in the university medical school" and asked surgeons to see that it is kept abreast of the times.

One admires the delicacy of feeling of the Minister who, when one Representative called the measure "coercion," expressed regret that the word was used. Asked by another whether the bill was intended to punish the doctors for not agreeing to free medical care, Mr Nordmeyer said he regarded it not as a penalty but as a concession to the doctors. He was unable, he said, to imagine any doctor refusing when someone asked what

would happen to a physician if he refused to be dragooned.

It is evident from the trend of events in New Zealand that an end is sought to all private medical service. The government can apparently muster sufficient votes to pass the bill. Short of a general strike which public opinion would not tolerate "the doctors appear," says the *Times*, "to have no weapon to oppose the measure." And that seems to be that.

Emergency Civilian Medical Service

Emergency Medical Service for Civilian Defense is now in the stage of active organization. In New York City Dr Edward M. Bernecker, general superintendent of city hospitals, has been appointed as its head and the medical and public health section of the New York City Health Preparedness Committee of the State Defense Council will serve as an advisory board.

Mayor La Guardia has wisely appointed the chairmen of the medical preparedness committees of the county medical societies to act as Chiefs of the Emergency Medical Service in their respective boroughs. They are Dr Condict W. Cutler, Jr., New York, Dr Edward R. Cunniffe, Bronx, Dr Thomas A. McGoldrick, Kings, Dr Harry P. Mencken, Queens, and Dr Herbert A. Cochrane, Richmond.

The action of the Mayor in appointing Dr Bernecker and the five borough leaders followed the recommendation laid down in the *Medical Division Bulletin No. 1*, of the United States Office of Civilian Defense of which Mayor La Guardia is the director and Dr George Baehr, the chief medical officer.

Paragraph one of the *Bulletin* deals with the appointment of the local chief of Emergency Medical Service, and in this state he will be designated by the Local Defense Councils.

Paragraph two of the *Bulletin* refers to a Local Medical Advisory Council on Civilian Defense. In New York State we have already set up County Health

Preparedness Committees to serve the counties and the cities therein. There is thus no need for a new committee.

At the present time, County Defense Councils have in their membership the chairmen of the County Health Preparedness Committees. It is suggested that each City Defense Council include in its membership, if it has not already done so, a member of the County Health Preparedness Committee for better liaison between the county committee and the City Defense Councils. The County Health Preparedness Committee can, and will, expedite the coordination of the medical facilities from which the civilian defense organization in the state is to be developed.

It is suggested by Dr Baehr that the chairmen of the Medical Preparedness Committees of the various county medical societies be appointed as Chiefs of the Emergency Medical Service in their localities. Chosen for their executive ability and standing in their individual county society these men are thoroughly familiar with the data so far accumulated by the committees which have been functioning for well over a year.

It is important that the efficiency and quality of our emergency medical service should be initiated and maintained at the highest possible level. The first and most obvious step in this direction is the appointment of the best qualified man as chief of that service. The county medical societies are in the best position to judge of the qualifications of such a

In July¹ we said "It is the foreign policy of the government which is now shaping, and will continue to alter further, the future of medicine" No-where is this more evident than in the field of medical education, as the above quoted report indicates. Plans for national defense must be predicated upon what we shall have to defend, where we must defend it and how. Any such plans must to a certain extent await the event. In the meantime, certain minimum demands must be met based upon authorized expansion of the armed forces, upon calculable, necessary expansion of industry and predicable civilian needs.

A broad view of what has been happening in the Nation seems to show a tendency to place domestic health and medical affairs under the expanding jurisdiction of the Social Security Administration in an attempt to coordinate them with plans, not yet fully disclosed, if indeed they have been condensed in tangible form from the nebular political mists which swirl and eddy about the Nation's capital. Forecasts in almost every kind of material thought to be necessary—excepting only money—have seemed to fall far short of eventually

proved necessity. One thing only seems clear. All proposals whether related to the probable demands of foreign policy or the exigencies of domestic affairs must be passed through the fine comb of the politico-social theorists at Washington. Nothing must interfere with the preservation of "social gains" no matter how closely related to reality it may be.

Since nobody apparently knows where our foreign policy will take us, or to what extent our "social gains" will anchor us, and since between the two a good deal of activity of one sort or another is going on, the picture in all its mystic beauty suggests a swarm of bees in an accordion. How, under such circumstances, medical educators can "preserve their institutions, and maintain, unimpaired, their priceless contribution to the health and welfare of the Nation," as well as to exercise foresight which is not merely plain guesswork, is beyond us. That they have successfully accomplished a great deal in the matter of reorganization, financing, and the maintenance of those standards that will produce a continuous supply of well-trained physicians in the face of unbelievable pressure and muddling, is a tribute to the soundness and adaptability of the structure of medical education in the United States.

That Bill Is in Again

Under the headline "New Zealand Gets Free Doctor Plan," the New York *Times* of September 8, 1941, describes a bill now before the House of Representatives by which national free medical care estimated to cost \$5,000,000 a year would be visited upon the people of New Zealand. Medical fees would be paid from the social security fund at the rate of \$1.00 for an office visit, \$1.25 for a house call, and \$0.25 a mile for travel over twenty miles. The government introduced the bill.

We have commented on the previous bill¹ which went into effect March 1,

1941. The Ministry of Health which is sponsoring this new bill must be credited with persistence if not with a sense of humor. To quote the *Times*: "One clause provides that the fees must be accepted as full payment and that a doctor may not demand nor be entitled to sue for further fees except by permission of the Ministry of Health."

Health Commissioner Nordmeyer stated before the Health Committee of the House, it is reported, that "the government was fixing one fee for all services though he said the government *presumed*² these would be the best the doctor was able to render."

SOLDIER'S HEART

LOUIS FAUGERES BISHOP, JR., M.D., New York City

THE title of this address was deliberately chosen to challenge attention to the fact that there should be no such thing as "soldier's heart" in this war. Why? Because we have accumulated over the years a knowledge of this condition, now called neurocirculatory asthenia, which should enable us to prevent its occurrence in the Army. All of us now realize what the heart and circulation of the soldier may be called upon to withstand. In these days the word "soldier" includes the aviator as well, who is called upon to endure the greatest of stress and strain. Obviously, the new factors of speed and acceleration and altitude will produce profound effects upon the circulation.

The solution to the problem of "soldier's heart" lies in prevention. And where does prevention begin in America? It begins with the Selective Service examination of the draftee. It should continue through the Induction Service. And it should *not* end when the recruit or trainee arrives in camp.

If we hope to eliminate heart disease in the soldier and take care of his heart, the circulation of a boy in the draft must not be superficially examined. Therefore, the first requisite for the prevention of potential soldier's heart is to have experienced medical examiners, coupled with psychiatric study.

But we have this advantage. We tackle the job of examining the heart and circulation of the draftees with greater accuracy by reason of the advance in knowledge of heart disease since the last World War. We *should* have more skilled ability to evaluate the soldier's heart than in 1918. We in America can *will* to avoid many of the errors of the last World War. What is the use of our progress in knowledge of heart disease if we cannot apply it to the draftee?

Surely the first examination of the draftee by the local board examining physician and his medical advisory board and, the second, the physical check-up by the board of specialists at the army induction centers should eliminate the unfit boy with an organically defective heart. And I believe it will.

But that elusive malady, "soldier's heart," is another matter. It is not an easy diagnosis to make rapidly. And *time* is a factor in the draft.

What is soldier's heart? "Called so far in this war 'neurocirculatory asthenia,' the name is purely descriptive of the major symptoms that are referable to the nervous and circulatory system and associated with an increased susceptibility to fatigue."¹

Soldier's heart has had numerous names from the time of the Civil War to any new label we may bestow on it in 1941. The most interesting term may contain a kernel of truth as to the nature of the disease—"D.A.H.," or "disordered heart action," popularly interpreted as "desperate affection for home." Apropos is a conversation I had with a trainee visiting New York City at Easter. I asked him what the soldiers at his camp talk about. He replied, "food and girls." There you have it—longing for the usual way of life—home! It is inherent in the normal, as well as the neurotic, recruit. Prevention must be on the alert for the neurosis that dogs the mind of the soldier away from his usual life and exposed to unusual mental and physical stress which may in turn affect his heart. Call it what you will, cardiac neurosis, effort syndrome, neurocirculatory asthenia, irritable heart, or anxiety neurosis, it is apparent that "soldier's heart" is a real disease, with far-reaching effects and as worthy of prevention as cancer!

The classic description of this subject, neurocirculatory asthenia, is contained in the article by J. M. Da Costa, one of the physicians to the Pennsylvania Hospital, in "Irritable Heart. A Clinical Study of a Form of Functional Cardiac Disorder and Its Consequences."² This study was published in the January, 1871, issue of the *American Journal of the Medical Sciences*. A study of this article, which is really a great medical classic, leaves no doubt in one's mind that Da Costa was writing about the condition now called neurocirculatory asthenia. In his original description he undoubtedly included some other forms of heart disease, but he had much the same experience with his cases that was again to happen in the World War of 1918 and that, with a fair degree of prediction, will happen again in this war. Evidently in every gen-

physician in the opinion of Dr Baehr and in this opinion the State Health Preparedness Commission concurs

The various counties are urged to act on this recommendation as soon as possible

Shortages

We have written before¹ that "major problems arising from altered economic concepts and practices are still but partly solved, and seemingly will be still further delayed in their solution, if not thrown out altogether, by the recent abrupt change that has precipitated the Nation into a war economy. One of the problems still very largely unsolved and related intimately to the domestic policy of government is that of medical care for welfare cases."

For a time, the increasing expansion of industry has reduced the relief rolls and has rendered less acute the deficiencies of the welfare program relative to the provision of good medical service. This does not mean that the problem has been solved. The lessened pressure has merely rendered existing conditions seemingly better.

Now there seems to be in prospect a new wave of industrial dislocations,

strikes, and unemployment. This will be occasioned by the shortages of materials in nondefense industries. It will impose new burdens on welfare medical service in the next few months. In many areas numerous physicians have been withdrawn for military service and more will be called shortly. Nursing personnel is already deficient.

We foresee many difficulties ahead unless some prompt forethought is given to a more effective arrangement than now exists for rendering good medical service to welfare patients. A shortage in civilian physician personnel will result inevitably in more cases being hospitalized. Hospital facilities are even now overtaxed in many areas of the state, not only in the matter of available beds but because of reduction in medical staff personnel. The prospect for the ensuing months seems to point to overcrowding, overwork, and a good deal of muddling around. A little planning would do no harm in the interest of the patient.

¹ The Future of Medicine, New York State J Med. 41 No 14 1429 (July 15) 1941

Undermining Medical Practice

If it were not so serious, one could derive a certain amount of amusement from the clamor that periodically arises when some branch of medicine is encroached upon by nonprofessionals and is tolerated and even encouraged by the law. In the years gone by ophthalmology has given birth to the optometrist and optician. General practice has sired the physiotherapist. Anesthetists are responsible for the large number of nurses who have intruded into the specialty. There has even been a movement to qualify laymen as "audiometrists" who would be eligible to test hearing with an audiometer.

We, as a whole, have no one but ourselves to blame for this situation. It is a result of carelessness, but more so of indolence in the performance of the time-consuming details attendant upon every branch of medicine.

Others have been quick to see the lucrative possibilities of these stepchildren of medicine. They have had our unconscious support in the development of these fields during the past decade and a half, when the medical profession was intense in the encouragement of specialization.

When the world depression began to affect the income of physicians, it began to dawn upon us that we had relinquished a considerable source of revenue which rightly belonged to the doctor. Rectification of the situation was impossible. There are still fields in which there is a tendency to relegate medical functions to laymen. In radiology, dermatology, and orthopedics—to name a few—one sees this inclination all the time. If we are not to be further encroached upon, it is up to us, and us alone, to stop it.

SOLDIER'S HEART

LOUIS FAUGERES BISHOP, JR., M D , New York City

The various counties are urged to act on this recommendation as soon as possible

Shortages

We have written before¹ that "major problems arising from altered economic concepts and practices are still but partly solved, and seemingly will be still further delayed in their solution, if not thrown out altogether, by the recent abrupt change that has precipitated the Nation into a war economy. One of the problems still very largely unsolved and related intimately to the domestic policy of government is that of medical care for welfare cases."

For a time, the increasing expansion of industry has reduced the relief rolls and has rendered less acute the deficiencies of the welfare program relative to the provision of good medical service. This does not mean that the problem has been solved. The lessened pressure has merely rendered existing conditions seemingly better.

Now there seems to be in prospect a new wave of industrial dislocations,

¹ The Future of Medicine, New York State J. Med. 41 No 14, 1429 (July 15) 1941

strikes, and unemployment. This will be occasioned by the shortages of materials in nondefense industries. It will impose new burdens on welfare medical service in the next few months. In many areas numerous physicians have been withdrawn for military service and more will be called shortly. Nursing personnel is already deficient.

We foresee many difficulties ahead unless some prompt forethought is given to a more effective arrangement than now exists for rendering good medical service to welfare patients. A shortage in civilian physician personnel will result inevitably in more cases being hospitalized. Hospital facilities are even now overtaxed in many areas of the state, not only in the matter of available beds but because of reduction in medical staff personnel. The prospect for the ensuing months seems to point to overcrowding, overwork, and a good deal of muddling around. A little planning would do no harm in the interest of the patient.

Undermining Medical Practice

If it were not so serious, one could derive a certain amount of amusement from the clamor that periodically arises when some branch of medicine is encroached upon by nonprofessionals and is tolerated and even encouraged by the law. In the years gone by ophthalmology has given birth to the optometrist and optician. General practice has sired the physiotherapist. Anesthetists are responsible for the large number of nurses who have intruded into the specialty. There has even been a movement to qualify laymen as "audiometrists" who would be eligible to test hearing with an audiometer.

We, as a whole, have no one but ourselves to blame for this situation. It is a result of carelessness, but more so of indolence in the performance of the time-consuming details attendant upon every branch of medicine.

Others have been quick to see the lucrative possibilities of these stepchildren of medicine. They have had our unconscious support in the development of these fields during the past decade and a half, when the medical profession was intense in the encouragement of specialization.

When the world depression began to affect the income of physicians, it began to dawn upon us that we had relinquished a considerable source of revenue which rightly belonged to the doctor. Rectification of the situation was impossible. There are still fields in which there is a tendency to relegate medical functions to laymen. In radiology, dermatology, and orthopedics—to name a few—one sees this inclination all the time. If we are not to be further encroached upon, it is up to us, and us alone, to stop it.

SOLDIER'S HEART

LOUIS FAUGERES BISHOP, JR., M D, New York City

THE title of this address was deliberately chosen to challenge attention to the fact that there should be no such thing as "soldier's heart" in this war. Why? Because we have accumulated over the years a knowledge of this condition, now called neurocirculatory asthenia, which should enable us to prevent its occurrence in the Army. All of us now realize what the heart and circulation of the soldier may be called upon to withstand. In these days the word "soldier" includes the aviator as well, who is called upon to endure the greatest of stress and strain. Obviously, the new factors of speed and acceleration and altitude will produce profound effects upon the circulation.

The solution to the problem of "soldier's heart" lies in prevention. And where does prevention begin in America? It begins with the Selective Service examination of the draftee. It should continue through the Induction Service. And it should not end when the recruit or trainee arrives in camp.

If we hope to eliminate heart disease in the soldier and take care of his heart, the circulation of a boy in the draft must not be superficially examined. Therefore, the first requisite for the prevention of potential soldier's heart is to have experienced medical examiners, coupled with psychiatric study.

But we have this advantage. We tackle the job of examining the heart and circulation of the draftees with greater accuracy by reason of the advance in knowledge of heart disease since the last World War. We should have more skilled ability to evaluate the soldier's heart than in 1918. We in America can will to avoid many of the errors of the last World War. What is the use of our progress in knowledge of heart disease if we cannot apply it to the draftee?

Surely the first examination of the draftee by the local board examining physician and his medical advisory board and, the second, the physical check-up by the board of specialists at the army induction centers should eliminate the unfit boy with an organically defective heart. And I believe it will.

But that elusive malady, "soldier's heart," is another matter. It is not an easy diagnosis to make rapidly. And time is a factor in the draft.

What is soldier's heart? "Called so far in this war 'neurocirculatory asthenia,' the name is purely descriptive of the major symptoms that are referable to the nervous and circulatory system and associated with an increased susceptibility to fatigue."¹

Soldier's heart has had numerous names from the time of the Civil War to any new label we may bestow on it in 1941. The most interesting term may contain a kernel of truth as to the nature of the disease—"D.A.H.," or "disordered heart action," popularly interpreted as "desperate affection for home." Apropos is a conversation I had with a trainee visiting New York City at Easter. I asked him what the soldiers at his camp talk about. He replied, "food and girls." There you have it—longing for the usual way of life—home! It is inherent in the normal, as well as the neurotic, recruit. Prevention must be on the alert for the neurosis that dogs the mind of the soldier away from his usual life and exposed to unusual mental and physical stress which may in turn affect his heart. Call it what you will, cardiac neurosis, effort syndrome, neurocirculatory asthenia, irritable heart, or anxiety neurosis, it is apparent that "soldier's heart" is a real disease, with far-reaching effects and as worthy of prevention as cancer!

The classic description of this subject, neurocirculatory asthenia, is contained in the article by J. M. Da Costa, one of the physicians to the Pennsylvania Hospital, in "Irritable Heart. A Clinical Study of a Form of Functional Cardiac Disorder and Its Consequences."² This study was published in the January, 1871, issue of the *American Journal of the Medical Sciences*. A study of this article, which is really a great medical classic, leaves no doubt in one's mind that Da Costa was writing about the condition now called neurocirculatory asthenia. In his original description he undoubtedly included some other forms of heart disease, but he had much the same experience with his cases that was again to happen in the World War of 1918 and that, with a fair degree of prediction, will happen again in this war. Evidently in every gen-

Chairman's address, read before the Section on Medicine at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

eration there are always unusual ways of life that shock the weak and nervously unstable

It would seem today that we are undoubtedly going to overlook a large number of recruits with this disease. It is true that it will come to light through somewhat of a sifting process after they have undergone training but probably will not be recognized to its fullest extent until these boys actually engage in warfare. Listen to what Da Costa has to say about handling this problem. After a classic discussion of the clinical side of the condition and the uselessness of drugs in treatment, he makes a number of interesting statements. "The treatment is never a short one, the worst cases had better not make any attempt to be soldiers of any kind, in the milder cases an attempt should be made to treat them and, if possible, send them back to their regiments to do anything except active service in the field." This is very much the attitude we have today toward neurocirculatory asthenia.

Hartshorne aptly described soldier's heart in 1864.³ He states, concerning the subject of "Heart Disease in the Army" "In a ward averaging about 80 patients" (he apparently had charge of a service in an army hospital following the Civil War) "I have met with the usual variety of cardiac affections. Acute endocarditis and pericarditis were the most rare. Of valvular diseases a few instances presented themselves, but knowing the lax manner in which, at the beginning of the war, the examination of recruits was conducted, it was impossible to judge satisfactorily of their antecedents or origin." He noted a few cases of enlargement, but this was not what particularly worried him. It was the large number of heart cases that he could not properly classify and that cannot be classified, even to the present day, so he coined the term "cardiac muscular exhaustion." Hartshorne also cites the address of Dr. A. Ställé,⁴ delivered before the Philadelphia County Medical Society and published in February, 1863, as the one published recognition of the disorder. Quoting Hartshorne "Although Dr. Ställé designates the disorder described by him as 'palpitation' of the heart, his account otherwise agrees so well with my own observations that I infer a general identity of the cases studied by us."

The symptoms of what Hartshorne called "cardiac muscular exhaustion" were much the same as those we note today in neurocirculatory asthenia. He remarked, for example, on the feebleness of the pulse while the patient is at rest and on the great acceleration of the heart movement on the slightest exertion—

still an important point in judging the nervous control of the circulation. Hartshorne described some of the rather vague and indefinite physical signs as he noted them and makes an interesting statement "that autopsic examination was not available to any extent in the investigation of these cases since the affection in the hospital, at least, was not mortal." His remarks about the availability of these men for active service are of particular importance because the same applies today. Hartshorne speaking again "Judging from what I have seen, I think it can hardly be a mistaken opinion that they are entirely unfit for ordinary field service in the army. They were so broken down by the 'double-quick' or even by the knapsack and musket alone. It would be not cruelty, but false economy, to compel them to undertake duty of which they are really incapable. No doubt many, perhaps most of them, would be able to do light service in various ways, but I am well satisfied that it would be cheaper and wiser, as well as more just, to discharge them than to return them to regimental duty before the exhausted heart has had time for full recuperation." All this was written back in 1864, but I am sure that someone else will dig up some earlier reference than this particular article and perhaps be able to refer back as far as there has been any knowledge of heart disease. However, I think these references are enough to indicate the early and long history of this problem.

The question of the soldier's heart in America begins at the point where the examinations for Selective Service are carried out. Volume 6 of Physical Standards of Selective Service Regulations, Section 14,⁵ outlines the usual procedure in examining the heart, lungs, blood vessels, and circulation of the draftee. If this examination is carried out with care, theoretically, at the present time no prospective soldier should be allowed to undergo a planned course of training unless he is fit. I speak from the standpoint of practical experience in examining the circulation of a large number of these boys because I have had an opportunity of serving on one of the local draft boards.

I find that it is reasonably easy to advise rejection when there is a clear-cut history of rheumatism and marked evidence of valvular defects, a well-defined example of congenital disease, or an occasional definite syphilitic heart. But it is hard to determine in the borderline problems whether a draftee will stand the wear and tear of training.

Any consideration of the soldier's heart of

today must also include the aviator's heart as well. For example, the most specialized requirement of the circulation of the aviation soldier is his cerebral circulation. It is interesting to note what special requirements must be met in order to enable a boy to be accepted in the aviation service from the cardiovascular standpoint. A survey of Armstrong's book, *The Principles and Practice of Aviation Medicine*, discloses extremely interesting data. In considering the underlying principles, he states "In aviation the cardiovascular system is important principally in relation to the maintenance of adequate tissue metabolism in order that the different organs of the body may operate continuously at a high level of efficiency."

As mentioned previously, of special importance is the maintenance of an adequate cerebral circulation for the support of consciousness. In other words, it is important that the heart of a soldier-aviator be adequate to keep the circulation to the brain intact. The conditions under which the aviator's heart operates are somewhat different from those of the soldier on the ground. For example, in flying, there is seldom, if ever, any physical activity sufficient to cause undue stress on the heart and blood vessels. The effect of altitude is not much different from that observed in mild exercise. It is particularly important that no possibility of a neurocirculatory asthenic condition is overlooked in the aviation soldier's heart. The acute psychic and emotional shock met with in wartime aviation may even lead to loss of consciousness in the unstable individual.

To measure up to the ideal, all soldiers and aviators should have a heart and circulation such as described by Schneider.⁷ He found that those factors such as make up what we term "athletic condition"—that is, a strong heart muscle, a highly efficient coronary circulation, and a good peripheral vasomotor control—all contributed markedly to increase altitude tolerance.

After twenty years certainly some of the mistakes of the last War in the appraisal of the circulation of soldiers will be eliminated. At that time large numbers of perfectly healthy individuals were rejected because of the presence of some signs whose significance the doctors were never taught to discount. It would seem that physiologic variations from the normal will not present to modern doctors such problems as those in the past.

I have never looked upon the diagnosis of heart disease as an easy matter. All of us

know that the symptoms of organic heart disease can be mimicked by nervous disorders, that the extracardiac causes of pain are manifold, that shortness of breath may come from many other causes than heart disease, and that various so-called circulatory symptoms—such as dizziness, syncope, pallor, or flushing—may not mean heart disease at all.

All of us know as well the difficulty of evaluating minor variations of physical signs from normal. That a diffuse apical beat does not mean heart disease, that percussion is not always reliable, that the position of the apex may vary, that heart sounds are sometimes not easy to appraise, that it is not simple to distinguish functional from organic murmurs. So appraisal of the normal heart should lead us all to take stock of ourselves—we should re-examine *ourselves* to see how much we know about some of these variations to avoid a few of the mistakes that were committed in the last World War. I might here recommend a useful pamphlet that can be obtained from the American Heart Association,⁸ called "Examination of the Heart."

Last year before this Section there was given a review⁹ of some of the recent advances in the study of the heart which included interesting methods of visualizing the chambers of the heart and great vessels, methods of recording the physiologic movement of the beating heart on a single film, and the new sensitive microphones and recording instruments for timing and differentiating murmurs. Also, there was a new idea in electrocardiography, such as the development of the lag-screen belt. By this device large numbers of persons, such as recruits, may be examined—such a method is useful when permanent records are necessary *only* if abnormalities are noted. There was also reported a new method of recording cardiac output by a mechanical device and methods of recording graphic registration of breathing—these (although used primarily for the study of pulmonary disease) may be important in differentiating whether dyspnea is of cardiac origin or is due to respiratory neurosis or to malingerers. Some of these newer methods of diagnosis are already teaching us more about neurocirculatory asthenia, for example, the method of ballistocardiography, the method of recording cardiac output, has shown that the cardiac output in neurocirculatory asthenia is reduced.

While it has been generally accepted that physicians know how to estimate the physical fitness of individuals, experience has shown that this is not easily done.¹⁰ There is no

eration there are always unusual ways of life that shock the weak and nervously unstable.

It would seem today that we are undoubtedly going to overlook a large number of recruits with this disease. It is true that it will come to light through somewhat of a sifting process after they have undergone training but probably will not be recognized to its fullest extent until these boys actually engage in warfare. Listen to what Da Costa has to say about handling this problem. After a classic discussion of the clinical side of the condition and the uselessness of drugs in treatment, he makes a number of interesting statements: "The treatment is never a short one, the worst cases had better not make any attempt to be soldiers of any kind, in the milder cases an attempt should be made to treat them and, if possible, send them back to their regiments to do anything except active service in the field." This is very much the attitude we have today toward neurocirculatory asthenia.

Hartshorne aptly described soldier's heart in 1864.³ He states, concerning the subject of "Heart Disease in the Army": "In a ward averaging about 80 patients" (he apparently had charge of a service in an army hospital following the Civil War) "I have met with the usual variety of cardiac affections. Acute endocarditis and pericarditis were the most rare. Of valvular diseases a few instances presented themselves, but knowing the lux manner in which, at the beginning of the war, the examination of recruits was conducted, it was impossible to judge satisfactorily of their antecedents or origin." He noted a few cases of enlargement, but this was not what particularly worried him. It was the large number of heart cases that he could not properly classify and that cannot be classified, even to the present day, so he coined the term "cardiac muscular exhaustion." Hartshorne also cites the address of Dr. A. Stillé,⁴ delivered before the Philadelphia County Medical Society and published in February, 1863, as the one published recognition of the disorder. Quoting Hartshorne: "Although Dr Stillé designates the disorder described by him as 'pulpitation' of the heart, his account otherwise agrees so well with my own observations that I infer a general identity of the cases studied by us."

The symptoms of what Hartshorne called "cardiac muscular exhaustion" were much the same as those we note today in neurocirculatory asthenia. He remarked, for example, on the feebleness of the pulse while the patient is at rest and on the great acceleration of the heart movement on the slightest exertion—

still an important point in judging the nervous control of the circulation. Hartshorne described some of the rather vague and indefinite physical signs as he noted them and makes an interesting statement: "that autopsic examination was not available to any extent in the investigation of these cases since the affection in the hospital, at least, was not mortal." His remarks about the availability of these men for active service are of particular importance because the same applies today. Hartshorne speaking again: "Judging from what I have seen, I think it can hardly be a mistaken opinion that they are entirely unfit for ordinary field service in the army. They were so broken down by the 'double-quick' or even by the knapsack and musket alone. It would be not cruelty, but false economy, to compel them to undertake duty of which they are really incapable. No doubt many, perhaps most of them, would be able to do light service in various ways, but I am well satisfied that it would be cheaper and wiser, as well as more just, to discharge them than to return them to regimental duty before the exhausted heart has had time for full recuperation." All this was written back in 1864, but I am sure that someone else will dig up some earlier reference than this particular article and perhaps be able to refer back as far as there has been any knowledge of heart disease. However, I think these references are enough to indicate the early and long history of this problem.

The question of the soldier's heart in America begins at the point where the examinations for Selective Service are carried out. Volume 6 of Physical Standards of Selective Service Regulations, Section 14,⁵ outlines the usual procedure in examining the heart, lungs, blood vessels, and circulation of the draftee. I speak from the standpoint of practical experience in examining the circulation of a large number of these boys because I have had an opportunity of serving on one of the local draft boards.

I find that it is reasonably easy to advise rejection when there is a clear-cut history of rheumatism and marked evidence of valvular defects, a well-defined example of congenital disease, or an occasional definite syphilitic heart. But it is hard to determine in the borderline problems whether a draftee will stand the wear and tear of training.

Any consideration of the soldier's heart of

pressure, at rest, above 150 systolic and 90 diastolic¹²

In our unit (Local Draft Board 41, New York City) for examining recruits, we have had some interesting experiences with the measurement of blood pressure. We have certainly verified to our own satisfaction what is so well known and often stated that it is a well-established fact that the systolic blood pressure is variable and that it reacts to various forms of external and internal stimulation. It has been stated truly that the systolic blood pressure is more easily influenced by excitement or exertion in the draftee with neurocirculatory asthenia than in a normal person.¹³

The determination of blood pressure is important from another standpoint if we are to agree with Hines¹⁴ that a transient elevation of systolic and diastolic blood pressure above a certain level should be regarded as evidence of a hypertensive regulating mechanism for blood pressure and that this hyperactivity is a precursor of sustained hypertension. There is no doubt that the examination of a recruit or trainee is in a sense a psychic pressor test. While it is probably not so consistent a standard test as the well-known Hines cold-pressor test, yet it may have a good deal of significance. It would only be by careful follow-up study and more detailed records of these examinations in recruits that we could work out any further important statistical data on this subject. The work of this draft has been so voluminous and has had to be done in such a short time that it has not been generally possible to set up any definite program of research along such lines. It is possible that during the coming draft important studies of this nature can be made.

From our study of this group of men it becomes clear that the range of normal blood pressure has not been definitely established. I think the important point to remember is that even transient elevations of diastolic and systolic blood pressure into the upper ranges of the so-called normal may be prognostic of probable subsequent hypertension.

We have made an interesting observation that just as the slow pulse seems to be quite unusual in examining recruits, hypotension also in our experience appears equally unusual.

Certainly a number of examples of neurocirculatory asthenia will be spotted by the Selective Service examination, others, by Induction Centers. But a comprehensive study of this problem will have to come after

soldiers have undergone training. Exactly by what methods of study, whether it be response to graded exercises or whether it be further refinement of functional tests, it is hard to say at this time.

All of these newer methods that have developed during the last years should help us in cases of differential or borderline diagnosis of the normal heart. In the light of our experience with past wars and in the knowledge we have gained of heart disease in civil life, together with what we have learned of newer examining methods and the aids of psychiatrists, we are still not going to eliminate entirely the question of neurocirculatory asthenia, because obviously the morale of the army is an important factor in the prevention of this disease. It is with an appreciation of the intangible nature of the morale factor with which I conclude this paper on the soldier's heart.

Although we hope that soldier's heart of other wars will not be a problem in our American army, it would seem from a study of this subject that if we are to prevent the development of this condition during and after the training period is ended the morale factor is important. Prevention of soldier's heart implies not only the weeding out of the unfit boys for the sake of themselves, their comrades, and the army, but prevention must be actively pursued in building up the morale of the boys in camp.

The medical profession will play no small part in this work. For example, just the giving of friendly instruction and adjustment to army routine reduced fainting from fear of inoculation from 40 to 2 or 3 per hundred.¹⁵

The most important points in the building of a morale have been only recently beautifully expressed in the DeForest speech by a young Yale undergraduate,¹⁶ which I should like to repeat. Like so many boys of our times, he was told by one of his elderly friends that he was glad that he would soon be out of it all, but that our young Yale friend would have to live through it all. This was the substance of the boy's reply.

"Through the threefold self-discipline of courage, faith, and understanding, the scales will fall from our eyes, and we shall see ahead to a future worth living in. Out of the Night itself we shall draw the inspiration to conquer by the power of the light that is in the mind of man. And beyond the sight of battling nation and a scarred earth, we shall catch a dreaming glimpse of peace and of new things in a new world."

clinical test that will accurately measure the functional capacity of a given heart. There are numerous useful tests, but no one test fits all possibilities. It is true that today we have many more mechanical devices to estimate cardiac circulatory function, but often they are too elaborate or they require too much apparatus and training in their use. Moreover they do not furnish much more than objective observations. For example, the recently advocated epinephrine test by King¹¹ for the determination of functional reaction to aid us in weeding out neurocirculatory conditions needs many more observations to guarantee its usefulness. But we must continue trying to get an accurate gage of the functional capacity of the soldier by every means of investigation and observation.

Functional capacity must be tested by exercises of longer or shorter duration. There is no doubt that in the final analysis this will be the only method of sorting out examples of neurocirculatory asthenia. I would recommend that a careful study of this problem of functional capacity and endurance be introduced when possible where men have started to undergo training.

In examining the heart and circulation of the draftee, I am sure I am only stating the usual obstacles that come up in examining large numbers of persons in a short time. But by calling attention to them, a few of these difficulties may be overcome.

A few of the impressions that we have gained in Local Draft Board 41 (New York City) are the following. We have found it important to examine the circulation of a draftee in an environment where there is as little noise as possible, otherwise the interpretation of the heart sounds is impossible. This is no easy matter when one is dealing with a large number of adults undergoing an examination for the army.

We have also found it imperative to have the draftee rest quietly for a few minutes rather than to *rush* into the examination, this sometimes happens when the boys are going from doctor to doctor in the Selective Service units that are set up.

I would like to mention a few impressions of some of the simple questions that arise in the course of examinations of the circulation. The first is that of the determination of the pulse rate and rhythm. Under the physical standards a pulse rate of 100 or over, that is persistent, is abnormal. In general, this is a fairly reliable criterion. In examining the draftees it is hard to know in some of the ex-

amples of rapid pulse which we encounter whether the increased rate will be persistent or not or how easily it will change under varying conditions. In general, it is my opinion that the boy with a labile pulse should not necessarily be rejected unless this is accompanied by other objective evidences of neurocirculatory impairment.

We have noticed that one of the common conditions that keeps the pulse rate up persistently, besides the more obvious possibility of an infection, is the effect of alcohol taken during the day of examination. We have found generally that alcohol speeds up the pulse, raises the blood pressure, and in general makes any evaluation of physical signs difficult. It is always a possibility that the draftee who is sensitive to alcohol or other drugs, such as tobacco, may be a potential candidate to develop neurocirculatory asthenia. This is a controversial question.

We have noted that extremely slow pulses are exceedingly rare and in our experience have not constituted any diagnostic problem as yet.

In general, it would seem that arrhythmias are also infrequent. In examining a large number of draftees, I have noted premature contractions in relatively few.

Sinus arrhythmia, a common finding in young adults, is frequent, but marked sinus arrhythmia is seldom noted.

It is not easy to determine rapidly the size of the heart in examining a large number of recruits, particularly since in Selective Service it must be done by physical signs alone. It has been noted that the boy with neurocirculatory asthenia usually has a small heart.

With regard to heart sounds and cardiac murmurs, the time-old question of whether a given murmur is functional or organic is still with us. One of the main handicaps in our unit is that we rarely have time to listen carefully enough in all positions and, after effort, to localize and clearly define a given murmur. A huge mass of work for the draft boards has grown up overnight.

The Selective Service booklet states that a persistent blood pressure, at rest, above 150 systolic or above 90 diastolic is cause for rejection.¹² Out of a total of 17,540 men examined between the ages of 21 and 35, 487 (or approximately 11 per cent) have been rejected in New York State for all complaints having to do with the heart, blood vessels, and circulation. Approximately 3 per cent of the 487 rejections have been due to a persistent blood

pressure, at rest, above 150 systolic and 90 diastolic.¹²

In our unit (Local Draft Board 41, New York City) for examining recruits, we have had some interesting experiences with the measurement of blood pressure. We have certainly verified to our own satisfaction what is so well known and often stated that it is a well-established fact that the systolic blood pressure is variable and that it reacts to various forms of external and internal stimulation. It has been stated truly that the systolic blood pressure is more easily influenced by excitement or exertion in the draftee with neurocirculatory asthenia than in a normal person.¹³

The determination of blood pressure is important from another standpoint if we are to agree with Hines¹⁴ that a transient elevation of systolic and diastolic blood pressure above a certain level should be regarded as evidence of a hypertensive regulating mechanism for blood pressure and that this hyperactivity is a precursor of sustained hypertension. There is no doubt that the examination of a recruit or trainee is in a sense a psychic pressor test. While it is probably not so consistent a standard test as the well-known Hines cold-pressor test, yet it may have a good deal of significance. It would only be by careful follow-up study and more detailed records of these examinations in recruits that we could work out any further important statistical data on this subject. The work of this draft has been so voluminous and has had to be done in such a short time that it has not been generally possible to set up any definite program of research along such lines. It is possible that during the coming draft important studies of this nature can be made.

From our study of this group of men it becomes clear that the range of normal blood pressure has not been definitely established. I think the important point to remember is that even transient elevations of diastolic and systolic blood pressure into the upper ranges of the so-called normal may be prognostic of probable subsequent hypertension.

We have made an interesting observation that just as the slow pulse seems to be quite unusual in examining recruits, hypotension also in our experience appears equally unusual.

Certainly a number of examples of neurocirculatory asthenia will be spotted by the Selective Service examination, others, by Induction Centers. But a comprehensive study of this problem will have to come after

soldiers have undergone training. Exactly by what methods of study, whether it be response to graded exercises or whether it be further refinement of functional tests, it is hard to say at this time.

All of these newer methods that have developed during the last years should help us in cases of differential or borderline diagnosis of the normal heart. In the light of our experience with past wars and in the knowledge we have gained of heart disease in civil life, together with what we have learned of newer examining methods and the aids of psychiatrists, we are still not going to eliminate entirely the question of neurocirculatory asthenia, because obviously the morale of the army is an important factor in the prevention of this disease. It is with an appreciation of the intangible nature of the morale factor with which I conclude this paper on the soldier's heart.

Discussion

Dr C Ward Crampton,* *New York City*—Not all the important points presented by Dr Bishop can be discussed. We must apply the principle of concentration and confine our remarks to a few important points.

1 The clinical concept variously called the "soldier's heart," disordered heart action (English), and neurocirculatory asthenia is not a single simple disorder. It is a complex compound of a series of related symptoms occurring in a variety of ways and arising from a variety of related causes. The disorder has its center in the autonomic nervous system. On one side of this center we have the structure of the heart, on the other, the structure of the mind. While this is not an organic disease of the heart (because the cardiac output can be quite "normal"), yet it may coexist with organic cardiac conditions with any other illness of the body. On the other side of the autonomic nervous system is the psyche and the emotional field with its various and diverse manifestations. Neurocirculatory asthenia, therefore, has three related and variable departments: (1) the structure of the heart, (2) the autonomic nervous system, and (3) the psyche.

2 While the heart itself is not characteristically diseased, yet the heart is usually structurally, functionally, and typically inadequate. It is commonly a poor heart—neglected, undeveloped, and untrained. This fact is commonly overlooked in discussions of neurocirculatory asthenia of the soldier's heart. Therefore, I wish to em-

phasize it. I should like to suggest the term "cardiac inferiority." More than half of the cases of soldier's heart (Lewis) come from the white collar class, neither physically fit nor physically trained for the strains of a rugged civilian life or the rugged life of a soldier. This carries two lessons. First, we as a nation should train our men to be physically fit and sufficiently rugged for something more than sitting on a chair. America glories in its athletes—Joe DiMaggio, Bob Feller, Leslie MacMitchell. All three together could not win a war. Americans typically take less exercise than the English and Germans. The typical American exercise is taken by vicariously reading about great games and great athletes in the newspapers or listening to radio descriptions of other people's athletic heroism. A good stirring broadcast will increase the rapidity of the heart beat 10, 20, or 30 per cent. People have died under the strain. But this vicarious exercise leaves the muscles cold and untrained. Americans think they are fit. As a nation they are not. We should get into training. *It takes longer to build a hardy, vigorous soldier's heart than it does to build a battleship.* Let America take heed.

3 Tobacco—It has been claimed by some neuropsychiatrists that tobacco is responsible for much neurocirculatory asthenia. One objects strongly to giving unlimited cigarette supplies to soldiers in neurocirculatory asthenia wards in hospitals. Nicotine is a typical autonomic nervous system disturber, it stimulates and then paralyzes. The autonomic nervous system is the central affected field in neurocirculatory asthenia. It would seem logical to blame tobacco, especially since the cigarette is smoked so much more in the Army than out of it. Lewis and McGregor, however, found neurocirculatory asthenia occurring in nonsmokers for example, the Sikhs in India. Oversmoking is not so commonly found in the previous record of these cases as infections of a notable character. These occurred in over half the cases. The distribution of smokers and nonsmokers in a series of neurocirculatory asthenia cases is approximately a soldier distribution. Tobacco poisoning from nicotine, however, can and does occur concurrently. Tobacco aggravates the symptoms of a fair proportion of cases but not all. It affects symptoms variously, usually adversely but not always. For example, tremor is typically increased by tobacco deprivation. Much more may be said on the relationship of tobacco and the soldier.

4 Recommendations—In the Army examinations now going on, the heart is examined. The routine test of the draft board, however, does not test the circulation, although a stepping test is offered to be given for reason. Let me emphasize this. The heart is examined as a routine, yes, the circulation, no. Circulation efficiency tests are given to aviators. The first one used was my test at Mineola Field by Captain (now Colonel)

* Major, Medical Corps U S Army Reserve

Schneider He added to this test some exercise and pulse recovery features that became the Schneider test. This is more useful and comprehensive, although less meticulously diagnostic than my test. The Army is now working with the "flamimeter," which adds the element of breath holding and endurance to the Crampton, Schneider, Master-Oppenheim groups of functional tests. It is hereby recommended that a test of the efficiency of the circulation be included in the draft board examination. This, depending on the test element selected, might add three to five minutes to the procedure. It would screen out a large proportion of potential neurocirculatory physical inferiors who will, unless something of this kind is done, produce the

same effect that they did in the last war. Then, millions of hours of hard labor by Army instructors, much patience, good intent, and good tempers were lost in trying to make a soldier out of something that never was and never could be made into a soldier within a year, two years, five years, or eternity. Coupled with this waste is the loss of millions of dollars of expense—first, in hospitals and treatment of these cases and, second, in giving them pensions. The way to remedy this is to be sought by study, perhaps by the appointment of a joint civilian military medical commission. From an assembly of basic facts and an assay of their values, a procedure may be devised to the advantage of both the Army and the rest of the nation.

Postgraduate Lectures

A course on *Traumatic Surgery* has been arranged by Dr. Henry H. Rutter, of the Reconstruction Unit, New York Post-Graduate Medical School, Columbia University, New York City, for the Steuben County Medical Society. The lectures will be given at Bath, New York, at 1 00 P.M.

10/ 2/41 Fractures in General. The Treatment of Common Fractures

Henry H. Rutter, M.D.,
New York City

10/ 9/41 The Treatment of Burns and Hand Infections

David Goldblatt, M.D.,
New York City

10/16/41 The Care of Head Injuries

Carl A. Peterson, M.D.
New York City

10/23/41 Bursitis, Sprains and Strains

Willis W. Lasher, M.D.,
New York City

10/30/41 The Treatment of Fractures of the Forearm and Leg

Emmett A. Dooley, M.D.
New York City

11/ 6/41 The Treatment of Fractures of the Femur and Humerus

Walter D. Ludlum, Jr., M.D.,
New York City

11/13/41 Nerve and Tendon Injuries

Ernest Lamps, M.D.
New York City

Dr. A. F. R. Andresen, Long Island College of Medicine, Brooklyn, has arranged lectures on *General Medicine* for the Westchester County Medical Society, at White Plains, New York, at 8 30 P.M.

9/10/41 Practical Considerations of Blood Dyscrasias

Dr. Eugene R. Marzullo
75 Remsen Street,
Brooklyn

11/12/41 Recent Advances in Therapeutics

Dr. George H. Roberts, Jr.,
48 Sidney Place,
Brooklyn

Dr. Robert A. Cooke, of New York City, has arranged a course on *Allergy* for the Queens County Medical Society.

10/ 9/41 Basic Factors of Allergy

William B. Sherman, M.D.,
New York City

New York City

10/30/41 Inhalant and Food Allergies

Will Cook Spain, M.D.,
New York City

CONTRARY LAWS

Two contrary laws seem to be wrestling with each other nowadays, the one a law of blood and of death ever imagining new means of destruction and forcing nations to be constantly ready for the battlefield—the other, a law of peace, work, and health, ever evolving new means of delivering man from the scourges that beset him. The one seeks violent conquests, the other, the relief of humanity. The latter places one human life above any victory while the former would sacri-

fice hundreds of thousands of lives to the ambition of one. The law of which we are the instruments seeks, even in the midst of carnage, to cure the sanguinary ills of the law of war, the treatment inspired by our antiseptic methods may preserve thousands of soldiers. Which of these two laws will ultimately prevail, God alone knows. But we may assert that science will have tried, by obeying the law of humanity to extend the frontiers of life.

† No autopsy obtained

disease was always interrupted we cannot be sure because many of these patients died as the result of the disease within a period of the ordinary life expectancy as computed from vital statistic tables

Craig and Adson,³ in 1937, reported on 27 patients subjected to extensive anterior root section. They recorded their results as follows: good, 13, fair, 6, failure, 6, deaths, 2. Smithwick,⁴ of Boston, has devised and used a type of splanchnicotomy which provides for the division of the communicating rami of the dorsals 9, 10, 11, and 12 with removal of the sympathetic trunk. In addition, lumbar 1 and 2 are interrupted, making the procedure even more radical than anterior root section. The results reported by him are most encouraging and bear further study.

Suprardiaphragmatic splanchnic nerve resection with the interruption of the thoracic sympathetic chain was performed in 12 patients and was well borne in all (Table 5). There were no complications or fatalities. The reduction in arterial pressure, which occurred following operation, within six months returned to the preoperative level in all patients. Subjective improvement—consisting of lessening in frequency and severity of headaches, decrease in the degree of nervousness, tenseness, and irritability—occurred in the majority of patients with essential hyper-

tension. Furthermore, the fatigue occurring on exertion was less evident. Improvement in those with malignant hypertension was transient.

Renal efficiency was unaffected by the operation. It also appeared to have no marked effect on the heart, as judged by electrocardiographic records or roentgen-ray photographs. Reduction in intensity of the constriction in retinal arterioles occurred in all of the cases except 1 with malignant hypertension, suggesting to us that arteriolar relaxation occurs in regions other than those denervated. We have observed this constriction to return after several months.

Peet, Woods, and Braden⁵ have reported the largest series of patients treated by suprardiaphragmatic splanchnicotomy and lower dorsal sympathetic ganglionectomy. They conclude that 86.6 per cent of the patients have been relieved of major symptoms such as headaches and that 81.3 per cent had improvement or complete restoration from incapacitation. However, 30 per cent of the patients operated upon were dead within a period of nine months to seven years and a

AN EVALUATION OF THE SURGICAL TREATMENT OF HYPERTENSION

GEORGE J HEUER, M D , and FRANK GLENN, M D , New York City

CARDIOVASCULAR renal disease ranks foremost among the causes of death in our present-day population. Hypertension plays an important role in this group. During the past decade a great deal of attention has been directed toward this subject. The laboratory investigator has developed a method for producing experimental hypertension in animals which should lead to a better understanding of its pathogenesis, the clinicians, both physician and surgeon, have extended their efforts. Old methods have been revised, new remedies are being brought forth, and surgical procedures have been introduced in our attempts to improve the treatment of patients. The surgical treatment of hypertension is as yet an experiment in therapeutics.

It is our purpose to present the data we have collected over a period of eight years in such an attempt and to comment briefly on the reports of similar studies recently appearing in the literature. During the first half of this period the work was followed in close cooperation with Dr Irvine H Page¹ of the Rockefeller Hospital. After Dr Page left New York and began work in Indianapolis, we continued this study entirely within the New York Hospital in collaboration with Dr Harold Stewart.²

Three types of operation have been employed. They are (1) rhizotomy, or division of the anterior nerve roots of the spinal cord, (2) supradiaphragmatic resection of the splanchnic nerves combined with lower dorsal ganglionectomy, and (3) subdiaphragmatic resection of the splanchnic nerves combined with interruption of the first and second lumbar sympathetic ganglions (Table 1).

TABLE 1—FIFTY-SEVEN HYPERTENSION PATIENTS

Anterior root section	23
Supradiaphragmatic splanchnic resection	12
Subdiaphragmatic splanchnicotomy and ganglionectomy, 1 and 2	22

Of these 57 patients selected for surgical treatment, the operative procedures were completed in 49. Of the 8 patients in whom the operation was not completed only 1 remains

alive. Of the 49 patients in whom the operation was completed, 23 are now dead. The time that has elapsed since operation varies from three months to six and one-half years (Table 2).

TABLE 2—ANTERIOR ROOT SECTION (23 PATIENTS)

Time elapsed since operation—four and one-half to six and one-half years
Operation incomplete in 4 patients
1 died near the end of the operation
1 died of meningitis after the first stage
1 refused to have the second stage and died two months later
1 developed a transverse myelitis after the first stage
Operation was completed in 19 patients
12 are dead 7 are alive

Rhizotomy, or anterior root section, consists in the division of the anterior nerve roots of the spinal cord from the sixth dorsal to the second lumbar vertebra. All the sympathetic fibers carrying vasoconstrictor impulses to abdominal vessels below the diaphragm are thus divided. This operation differs from splanchnicotomy because the preganglionic fibers are divided instead of the postganglionic rami.

The operation is usually performed in two stages. The first consists of a laminectomy with exposure of the dura, the second consists of the opening of the dura and division of the nerve roots. This is a formidable procedure, one that is time-consuming and not without danger because of the possibility of an accident to the cord with the appearance of the symptoms of a transverse myelitis (Tables 3 and 4).

Of 23 patients selected for this operation, 19 were carried on to completion and, of these 19, 7 are now alive. All of those who had severe malignant hypertension at the time of the operation are dead. Three years and nine months was the longest period to elapse between operation and death in this group. Following operation there was a fall in blood pressure which, over a period of two to three years, approached but seldom reached or surpassed the preoperative level. The subjective and some of the objective manifestations of the disease were definitely relieved. Specifically, we refer to the striking relief from headaches, nervousness, and early fatigue on exertion. In many of these patients we observed the disappearance of papilledema and hemorrhage from the fundi following operation. That the

Twenty-two patients were selected for subdiaphragmatic splenectomy and interruption or resection of the first and second lumbar ganglia. The operation was carried to completion in 18 cases (Table 8). Two patients with severe malignant hypertension died after the first operation in uremia, 1 died of a cerebral accident after the first operation. One patient refused the second operation and died. The reduction of the blood pressure which occurred following the operation was marked but tended to return to the preoperative level within a period of six months.

There was marked subjective improvement in many of the patients, consisting of lessening in frequency and severity of headaches, nervousness, tenseness, and irritability and a decrease of fatigue (Table 9).

The renal efficiency was unaffected by the operation as indicated by urinary findings and the urea clearance test. The heart has not been observed to undergo any changes as determined by electrocardiographic records or roentgen-ray examination. Reduction in intensity of constriction of the retinal arterioles has occurred in the majority of patients whose pressure has been lowered. With a re-elevation of the blood pressure some patients failed to exhibit a return of this constriction (Table 10).

Adson² reported from the Mayo Clinic their experience with subdiaphragmatic splenectomy as follows. Good, 29, fair, 35, temporary improvement, 35, and failures, 25. These results were based on a two-year or more check-up. He and his associates recom-

mend the procedure because of its comparative safety and fairly high beneficial results. In Boston, Smithwick⁴ was unsatisfied with his results in this operation and has supplemented it in an attempt to denervate more completely the splanchnic area.

The medical and surgical treatment of hypertension is admittedly, for the most part, ineffective. By medical treatment we refer to that therapy which is dependent upon the use of various medications and the employment of those regimens outlined by any physician. The surgical treatment of hypertension, on the other hand, consists of the direct attack upon the disease by a surgical procedure. These attacks have been carried out by a few surgeons in the United States and have consisted of operations interrupting or removing those parts of the sympathetic nervous system which are believed to control the blood supply of the kidney and splanchnic area. From the figures that we have presented, it is evident that the procedures we employed are not sufficient to cure or interrupt the progress of this disease.

Of great importance in our experience, however, has been the alleviation of symptoms which has occurred so frequently in this group of cases that we can, without hesitating, state that the patients as a whole have been benefited. This statement would be valueless indeed if we were unable to be more specific. It is for this reason that we have selected the

three most common symptoms associated with the hypertensive patients as a subject for critical investigation so far as our surgical therapy is concerned. These symptoms are (1) headache, (2) nervousness, and (3) fatigue on exertion.

Of the 57 patients selected for operation, one of the three procedures described was carried to completion in 49. Headache was one of the three chief complaints in 48 cases. Forty-five of these patients were completely relieved of headaches for a time following operation. Many of them have had no headaches since, although the time elapsed since operation has extended up to six and one-half years.

It has been our experience from prolonged observations of these hypertensive patients that many of them complain of nervousness, a sense of tenseness, and hyperirritability that are difficult to correlate as a single manifestation of the disease. We have sought to group these manifestations under one presenting symptom labeled nervousness. It is second only in importance to headaches. It is this symptom that prevents the hypertensive patient from resting, adds so much to his general discomfort, and makes him so susceptible to disturbing stimuli that the first complaint of headache may be precipitated.

Following operation, 36 of the 49 patients have been completely relieved of this symptom, 8 have been partially relieved, and in the remainder it was difficult to determine whether

majority of these died from the cardiovascular renal disease. To us, their report is optimistic indeed because they have had relief of symptoms in so many patients with apparent interruption of the progress of the disease.

Although our series is quite small—there were only 12 patients—they have been carefully studied and selected for operation (Tables 6 and 7). The eldest was 48 and the youngest 18, the diastolic pressure was 120 or over in each instance. Within a period of about five years after operation, 6 patients are alive and 6 are dead, with the exception of 1 patient who died at three months after operation and at postmortem examination was found to have a pheochromocytoma, all lived from one year to five years and three months and died of cardiovascular disease. Those who remain alive have been, for the most part, markedly improved. They have had relief of symptoms and lowering of blood pressure to the extent that 4 have returned to their regular occupations. The remaining 2 patients, we feel, are better than they would have been without the operation. However, we cannot cite in this group an instance of complete cure with total relief of symptoms, a maintained normal blood pressure, and a return of the vessels to normal limits.

Twenty-two patients were selected for subdiaphragmatic splanchnicotomy and interruption or resection of the first and second lumbar ganglia. The operation was carried to completion in 18 cases (Table 8). Two patients with severe malignant hypertension died after the first operation in uremia, 1 died of a cerebral accident after the first operation. One patient refused the second operation and died. The reduction of the blood pressure which occurred following the operation was marked but tended to return to the preoperative level within a period of six months.

There was marked subjective improvement in many of the patients, consisting of lessening in frequency and severity of headaches, nervousness, tenseness, and irritability and a decrease of fatigue (Table 9).

The renal efficiency was unaffected by the operation as indicated by urinary findings and the urea clearance test. The heart has not been observed to undergo any changes as determined by electrocardiographic records or roentgen-ray examination. Reduction in intensity of constriction of the retinal arterioles has occurred in the majority of patients whose pressure has been lowered. With a re-elevation of the blood pressure some patients failed to exhibit a return of this constriction (Table 10).

Adson³ reported from the Mayo Clinic their experience with subdiaphragmatic splanchnicotomy as follows: good, 29, fair, 35, temporary improvement, 35, and failures, 25. These results were based on a two-year or more check-up. He and his associates recom-

CONTROL OF PAIN AND DISCOMFORT BY THE SUBCUTANEOUS INJECTION OF OXYGEN

JOHN H. EVANS, M D , Buffalo

BEFORE coming to the subject matter of this paper I should like to say a few words about the development of our specialty which I have followed with great interest during the twenty-eight years I have been an anesthetist.

In 1913 anesthesia was a neglected and un-honored field. Today it is receiving world-wide attention and is recognized as one of the most important of the specialties.

In 1913 there were only a few physicians who condescended to give anesthetics, while today there are over 2,000, all of whom are proud of being classified as anesthetists.

In 1913 organization of professional anesthesia was in its infancy. Today, we have the International Anesthesia Research Society, the American Society of Anesthetists, Inc. and a section in the American Medical Association as well as in many state medical societies. In addition, anesthesia societies have been organized in nearly all of the foreign countries and there are many local societies in the large cities of the United States and Canada.

In 1913 there was no publication devoted to anesthesia, the occasional article written on the subject being published in the various medical journals, and textbooks on anesthesia were few. Today we have two journals in this country devoted exclusively to anesthesia—namely, *Current Researches in Anesthesia and Analgesia* and *Anesthesiology*. We also have textbooks that cover all types and methods of administering anesthetics and *Anesthesia Abstracts* of which the tenth volume is now on the market. In England *The British Journal of Anesthesia* made its debut in 1927.

In 1913 instruction in anesthesia was limited. Many of the medical colleges did not even include it in their curriculum, and the graduate in medicine was not required to have any knowledge of the subject. The few who were desirous of learning the art and science of anesthesia found there was no place to go and their practical knowledge could be obtained only by the trial-and-error method. The designation "Professor of Anesthesia" did not exist.

Today, instruction in the various phases of

anesthesia is given in all medical colleges, many of them having chairs in anesthesia, the medical student cannot graduate without some knowledge of the subject and there are several teaching hospitals where a three-year fellowship can be acquired.

This remarkable change in the status of anesthesia has been brought about by the efforts of many professional and scientific workers whose object has been to make surgery safer for the patient. The list is too long to give each one the credit he deserves at this time. However, I cannot refrain from mentioning one who devoted his entire life to the advancement of anesthesia and to whom we owe much for the present high standards of our specialty—namely, the late Dr. Frank H. McMechan.

The specialist in anesthesia was formerly confined to the administration of anesthetics but during recent years he has taken on additional responsibilities.

In my presidential address at the Sixth Annual Congress of Anesthetists in 1927¹ I made two recommendations: (1) that inhalation therapy be combined with the specialty of anesthesia, and (2) that 100 per cent oxygen be used in the treatment of anoxemia to replace the ineffectual 40 to 60 per cent oxygen dosage then in vogue.

The first of these recommendations met with prompt approval. Not only has inhalation therapy been added to our specialty but in several hospitals therapeutic nerve block and blood transfusions have also been allotted to the department of anesthesia.

The recommendation relative to 100 per cent oxygen for years met with vigorous opposition² notwithstanding the frequent publications³ regarding its safety and desirability. However, in recent years considerable progress has been made. There are several⁴ who now advocate and use 100 per cent oxygen but who are apparently still imbued with fear of its prolonged administration, otherwise they would not reduce the oxygen concentration to 50 to 70 per cent after forty-eight hours although dealing with severe anoxemia.

It has been shown repeatedly⁵ that these patients are still cyanotic while inhaling 60 per cent oxygen and are often in the death zone of asphyxia. The comfort, and often the

¹Chairman's address, read before the Section on Regional and General Anesthesia at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

or not this symptom had been effected. We are aware that the realization that an operation has been performed for a serious condition may do much to place the mind of the individual at rest and enable him to relax more readily than before. However, we are convinced that there is something much more tangible and actual than this and that the patients are not exaggerating when they claim they are much less nervous.

Early fatigue on exertion associated with hypertension was present in all of the patients. From a review of their history and from discussions with the patients it is felt that only 34 or 59.6 per cent actually complained of early fatigue. Patients in whom headaches were severe and who were subject to a state of nervousness and tenseness were most frequently prone to complain of fatigue on exertion. This is not unexpected because both the first and second symptoms are likely to prevent the patient from securing a normal amount of rest and, in addition, consume energy that otherwise would not be required. Furthermore, there is the lack of reserve so far as the heart is concerned, together with the added work that is required of it. These manifestations of the disease are of tremendous importance to the patients, and to relieve them either by medical or surgical means is to make life more pleasant for them and probably prolong it as well. Unfortunately, we do not possess instruments of accuracy for measuring such improvement. If we were but able to measure the increase in intensity of these symptoms as we are able to measure the blood pressure with the mercury manometer, perhaps we would be justified in

being more adamant in insisting upon the surgical treatment of these unfortunates.

The surgical treatment, consisting of the above three described operations, was embarked upon as an experiment. We have carefully studied a small group of patients in an effort to determine the merit of this therapy. We believe further investigation with this type of therapy is indicated because (1) it has been followed by a lowering of blood pressure as a result of the operative procedures, (2) changes in the fundi have occurred and in many cases persisted, (3) headaches have been relieved for variable periods of time, (4) nervousness has been diminished, and (5) early fatigue has been lessened.

Now, because we find among these five factors a ray of hope, we urge the continuation of surgical therapy on an experimental basis, employing even more complete operations in denervating the splanchnic area such as that described by Smithwick.⁴ Improvement in the methods of surgical attack upon this disease may provide for its interruption as well as the alleviation of symptoms. If this can be done, the surgeons will have made a contribution to the treatment of cardiovascular renal disease.

1942 Registration Cards Delayed

[From Dr. Robert R. Hannon, Secretary of the New York State Board of Medical Examiners, came the following announcement on September 26.]

"Due to a reorganization of the office procedure in annual registration and delay caused by conditions arising from national defense restrictions the Department will not be able to send application cards for annual registration for the calendar year 1942 to physicians until early November. This delay is unavoidable but the application cards will be mailed as early as possible."

about and the pain relieved is a difficult question to answer satisfactorily

The oxygen, in cases of acutely inflamed joints, muscles, or nerves, probably has a three-fold action. (1) It seems to act as a buffer between inflamed cells, separating them, opening lymph channels for drainage, and reducing pressure, (2) it probably kills certain types of bacteria, and (3) it may neutralize toxins and stimulate local circulation of blood

The clinical results have been so uniform in acute conditions that it is possible to predict them in advance, usually there is prompt relief of pain, within twenty-four hours the local temperature drops, the redness disappears, the swelling is reduced, and the tissues become much less sensitive to pressure

The beneficial results obtained in chronic conditions are probably due mainly to the same factors as in acute cases. However, as there are more pathologic changes—such as thickened tissues, induration, diminished blood and oxygen supply—more time is required to produce results, and in some cases none have been obtained. Apparently the function of pure oxygen when it comes in contact with abnormal tissue is to soften it so that absorption eventually takes place. This effect has been observed to occur in stiff fingers following infection, the palmar nodules of early Dupuytren's contracture, and the persistent areas of induration at the site of hyperdermics of drugs

X-rays show that the oxygen not only fills the subcutaneous spaces but permeates the deeper tissues until it reaches bony structure. This explains why results are possible in other than superficial conditions

Acute Inflammatory Conditions

Among the acute diseases for which we have found subcutaneous oxygen to be beneficial are atrophic and hypertrophic arthritis, sciatica, shingles, myositis, neuritis, lumbago, boils, and abscesses. None of the infections treated were tubercular. An advanced case of erysipelas was treated but without results. The number of injections necessary in acute cases vary. In some, one injection only has been sufficient, while others, especially in acute atrophic arthritis of the knees, may require treatment for several weeks before a return to normal is accomplished

Trauma

The pain, swelling, and tenderness resulting from trauma responds to oxygen in a similar manner as in acute inflammatory conditions

However, when there is marked swelling the pain may be increased for the first ten to twelve hours, after which it is either greatly reduced or disappears. The tenderness in these cases, as in acute conditions, persists after the pain has gone, gradually disappearing in a few days. Apparently, the oxygen hastens the repair of damaged tissues and function is restored sooner than when oxygen is not used

The following are 2 cases of pain relief following trauma

1 A dentist, aged 45, a week after the reduction of a dislocated hip, suffered severe pain when walking, which he did with the aid of a cane. Immediately after the injection of oxygen he was able to walk without his cane and with little pain. The following day the pain had all disappeared and did not return

2 The right hand of a woman, aged 53, became swollen, cold, cyanotic, and painful fourteen weeks after a Colles fracture. It looked as though amputation would be necessary. There was some relief of pain after the first injection of oxygen and less cyanosis. Following the second injection nearly all the pain disappeared and the color of the hand became pink. The treatment was continued for two months, three injections being given weekly, with complete recovery

Skin Diseases

Although our experience with skin lesions has been limited, the good results obtained in some of the cases indicate that this might be a fertile field for further investigation. Several cases of eczema have been treated with benefit. There was only 1 case, diagnosed as contact dermatitis, that showed no improvement

Oxygen has also proved beneficial in cases of ringworm

Pruritus Ani

Subcutaneous oxygen is probably the best remedy for pruritus ani that has so far been found

Apparently the first patient ever to be given this treatment was a man, aged 48. The pruritus ani was of eighteen months' duration and was complicated by a dermatitis involving the buttocks and the inner aspects of both thighs. He had been treated by his family physician and for the last four months by a skin specialist, but without any improvement. The itching was relieved after the first injection of oxygen and the dermatitis was improved. From November 19, 1935, to December 21, 1935, he was given three treatments a week, at which time the itching and dermatitis had disappeared and treatment was discontinued. On February 7, 1936, the patient returned complaining of a re-

life, of the patient depends on keeping the arterial blood oxygen at its normal level not only for a forty-eight-hour period but for as many days or weeks as the cause of the anoxemia persists. Is it just to the patient or good therapeutics to limit arbitrarily dosage with entire disregard to physiologic requirements?

The word "anesthesiology" has been coined to cover the enlarged field of the anesthetist, and this designation has been approved by the American Medical Association and the American Boards.

Subcutaneous Oxygen

Although Damarquay⁵ in 1865 announced the cure of a case of senile gangrene by the injection of oxygen, little attention was given to this type of therapy until 1911. Since then there has been a steadily growing interest so that at the present time the literature on the subject is quite extensive.

For many years it was used to a greater extent in Europe than in this country. The great majority of clinicians who have employed this therapy have injected the oxygen into healthy tissue, relying on the increase in the oxygen content of the blood for beneficial results. It has been used mostly in the diseases and conditions of which anoxemia is a complicating factor.

Even in the treatment of localized lesions and diseases the oxygen was usually injected into healthy tissue remote from the pathology.

The oxygen has, however, been given in the past to a limited extent for its local effect, but in general the importance of direct contact between oxygen and diseased tissues has been overlooked.

When, in 1935, I decided to investigate the merits, if any, of subcutaneous oxygen in diseases not complicated by anoxemia, it was with the idea of increasing the oxygen content of the blood by injecting the oxygen into healthy tissue. However, as this method failed to produce any beneficial results in the first case treated—which was for eczema—the oxygen was injected directly into the affected areas. The results were surprising. When the patient returned forty-eight hours later for his second treatment the eczematous areas were greatly reduced in size and there was much less itching. After six weeks, the injections being given three times weekly, there was complete disappearance of the eczema and itching.

It was then decided that in the future the

oxygen should, when possible, be injected directly into the diseased tissues. The importance of following this rule was subsequently proved in cases of acute arthritis by injecting the oxygen into healthy tissue remote from the pathology. This was done for four consecutive days, but no benefit was obtained until the oxygen was injected directly into the affected areas.

Another rule was later adopted—namely, that when it was not feasible to inject the oxygen directly into the pathology it should be injected as close to it as possible. The basis for this rule was the good results obtained in a prolonged attack of asthma when the oxygen was injected in each side of the spine in the thoracic region. For two days previous the continuous inhalation of 100 per cent oxygen plus the injection of oxygen into the thighs and abdominal wall had proved ineffectual.

The injection of oxygen in the back, while not always successful, has proved equally beneficial in several other similar cases, the asthmatic attack beginning to subside as soon as the oxygen was injected and disappearing entirely in from three to five days.

The reason for the good results obtained in these cases cannot be credited to any increase in the arterial blood oxygen since no more oxygen was injected in the back than in the other locations. The effect on the spinal nerves, brought about by reduction of pressure due to localized edema, and the improved circulation produced by the oxygen may be possible explanations. The nervous system is more quickly affected by reduction in normal oxygen supply than the other tissues.

The injecting of oxygen in the back for the treatment of pathology in the chest and abdominal cavity has not been as yet thoroughly investigated, but encouraging results have already been obtained in a few conditions, such as relief of pain and discomfort in cases of angina pectoris, coronary thrombosis, cardiac dyspnea, and nephritis.

It is not possible within the scope of this paper to give more than a general idea of the results obtained with subcutaneous oxygen during the past five years. A detailed report of 100 cases covering the first year's work was published in 1937.⁶

We have found that relief of pain and discomfort can be obtained in a variety of pathologic conditions. Unlike nerve blocking from which we can expect relief of pain only, the oxygen usually has a beneficial effect upon the pathology. Why this effect is brought

about and the pain relieved is a difficult question to answer satisfactorily

The oxygen, in cases of acutely inflamed joints, muscles, or nerves, probably has a three-fold action (1) It seems to act as a buffer between inflamed cells, separating them, opening lymph channels for drainage, and reducing pressure, (2) it probably kills certain types of bacteria, and (3) it may neutralize toxins and stimulate local circulation of blood

The clinical results have been so uniform in acute conditions that it is possible to predict them in advance, usually there is prompt relief of pain, within twenty-four hours the local temperature drops, the redness disappears, the swelling is reduced, and the tissues become much less sensitive to pressure

The beneficial results obtained in chronic conditions are probably due mainly to the same factors as in acute cases. However, as there are more pathologic changes—such as thickened tissues, induration, diminished blood and oxygen supply—more time is required to produce results, and in some cases none have been obtained. Apparently the function of pure oxygen when it comes in contact with abnormal tissue is to soften it so that absorption eventually takes place. This effect has been observed to occur in stiff fingers following infection, the palmar nodules of early Dupuytren's contracture, and the persistent areas of induration at the site of hyperdermics of drugs

Pruritis Ani

Subcutaneous oxygen is probably the best remedy for pruritis ani that has so far been found

Apparently the first patient ever to be given this treatment was a man, aged 48. The pruritis ani was of eighteen months' duration and was complicated by a dermatitis involving the buttocks and the inner aspects of both thighs. He had been treated by his family physician and for the last four months by a skin specialist, but without any improvement. The itching was relieved after the first injection of oxygen and the dermatitis was improved. From November 19, 1935, to December 21, 1935, he was given three treatments a week, at which time the itching and dermatitis had disappeared and treatment was discontinued. On February 7, 1936, the patient returned complaining of a re-

turn of the pruritis ani and itching from small areas of dermatitis on both thighs. Treatment was resumed and continued for six weeks. Since that time, a period of over five years, there has been no return of the itching or skin condition.

I then treated several cases weekly at the Outpatient Department of the Buffalo General Hospital. While one treatment a week was beneficial, the dosage was inadequate to do justice to the oxygen. Dr. Harry C. Guess, proctologist of Buffalo, continued the investigation on his private patients and reports 80 per cent of cures in a series of over 250 cases.

Arterial Diseases of the Extremities

Pain in the hands and feet due to restricted circulation has in the majority of cases been relieved by the injection of oxygen. These include arteriosclerosis, Berger's disease, and Raynaud's disease. Gangrenous areas have healed and probably amputation has been avoided in 3 cases. The following case is an example.

A woman, aged 76, with hypertension and arteriosclerosis, began to have cold and painful feet in July, 1937. She was treated with an alternating positive and negative apparatus without any relief. When the subcutaneous oxygen treatment was begun on February 5, 1938, the distal half of the second toe on the right foot was gangrenous and the other half was cyanotic. Blood pressure was 210/86. Three injections of oxygen were given weekly until April 24, 1938, at which time the protruding bone of the toe was nipped off under nitrous oxide-oxygen anesthesia. As the blood supply to the remaining part of the toe was good and as there was no more pain, the oxygen treatments were discontinued. The toe healed and the patient has had no pain or gangrenous areas since—a period of over three years.

There was 1 case of beginning gangrene of the feet with severe pain which, after four injections of oxygen, was not benefited. This was a man, aged 84, with marked arteriosclerosis. He died a few days later of cerebral hemorrhage.

Two patients with diabetic gangrene were treated for a month without results.

In cases of Berger's disease and Raynaud's disease when there is no marked edema, the patient can be relieved of pain and numbness to a great extent and the fingers or toes can be kept from sloughing. Cracking of the skin and some ulceration will occur in most cases in spite of three weekly injections of oxygen.

The following is an example of the ability of oxygen to check sloughing.

A man, aged 50, had had Raynaud's disease since 1924. In January 1937 the distal half of the right index finger was amputated at the Mayo Clinic. In May, 1941 the left index finger began to slough at the distal end and had progressed to about the same degree as had the right before the amputation. Subcutaneous oxygen was given for two months, three times weekly. The pain was relieved, the sloughing was checked, and the finger healed.

Angina Pectoris and Coronary Pain

The results in 10 cases of precordial and sub-sternal pain have been quite uniform. Usually, there is immediate relief as soon as the oxygen is injected into each side of the spine in the thoracic region, and in twenty minutes the pain is either almost or entirely gone. The freedom from pain lasts from one to three days but can be brought on by overexertion or emotional upset. In 4 of these cases the diagnosis of coronary occlusion was confirmed by electrocardiograms.

While relief of coronary pain can usually be obtained by the inhalation of 100 per cent oxygen, it is not so effective or so lasting as with subcutaneous oxygen. Occasionally, a patient will be little, if any, benefited by the inhalation of 100 per cent oxygen. The following is an example.

A man, aged 43, had severe sub-sternal and precordial pain, which was diagnosed by a competent heart specialist as due to coronary thrombosis. He was put to bed and 100 per cent oxygen therapy by inhalation was instituted. In spite of the oxygen, which was given continuously for the first twelve hours and thereafter twenty minutes each hour for three days, the pain, while somewhat less, was still severe. Large doses of morphine had also been given during this time. About 1,000 cc. of oxygen was then injected into the back, the procedure requiring about twenty minutes. As soon as the injection was completed the patient said that there was not enough pain left to mention. Two days later he refused to take another injection because he had been so comfortable and free from pain. During this time he had no inhalation oxygen.

The clinical results in the following case are interesting because of the definite pathology found in the heart at autopsy.

A man, aged 62, was known to suffer from hypertension and cardiac disease since 1933. Diagnosis after admission to the Buffalo General Hospital on July 17, 1939, was arteriosclerosis, hypertension, and coronary occlusion, confirmed by electrocardiograms. Since 1933 he had had many severe attacks of precordial pain and

dyspnea, sometimes lasting for many hours. After discharge from the hospital on July 29, 1939, the pain continued to be severe and prolonged. Some relief was obtained by nitroglycerine, but there was no relief from irradiation of adrenals. On February 1, 1941, the patient was referred to me for treatment at the Outpatient Department, he reported only once a week. The following notations are taken from the patient's chart "February 8, 1941—had no pain for three days after first treatment except on sudden exertion or when walking rapidly. Appetite has improved and sleeps better. February 15, 1941—an hour after last treatment had pain for about four hours but since then has been free not only from pain but also precordial distress for long intervals. February 22, 1941—had a comfortable week with no sharp pain but some precordial ache on exertion. March 1, 1941—no pain for three days following last treatment and says he feels several years younger." During the next two weeks he was given two injections a week.

"March 5, 1941—feels better generally. No pain in chest until this morning. March 8, 1941—no pain since last oxygen treatment until today after walking from his home to the hospital, a distance of over half a mile. March 12, 1941—was free from pain for twenty-four hours following last treatment. March 15, 1941—no sharp pain since last treatment. March 22, 1941—has taken only four nitroglycerine tablets during past week for occasional pain. March 29, 1941—felt good the past week. Took only one nitroglycerine tablet which was this morning. Has taken long walks without pain or dyspnea."

He died suddenly on April 8, 1941, ten days after the last oxygen injection.

Autopsy Report.—Distinct concentric myocardial hypertrophy of the left ventricle. Marked arteriosclerotic changes of the coronary arteries, particularly the left circumflex and the right marginal branches, which do not admit a probe. No recent thrombus discovered. Plum-size Rokitsansky aneurysm on the posterior wall of the left ventricle with almost complete fibrous replacement of the myocardium at this point. On section, distinct myocardial fibrosis in septal wall.

Nephritis

The beneficial results in 3 cases of nephritis which coincided with the initiation of subcutaneous oxygen injected in the back is encouraging and is reported at this time with the idea of stimulating further investigation. Two of the cases were chronic and 1 was acute.

The acute case was a woman, aged 48, and the glomerulonephritis was a complicating factor of a recent pneumonia. When subcutaneous oxygen therapy was begun on February 20, 1936, the blood pressures were 165/90 and there

was 4 plus albumin in the urine. The injections were given daily for the first two weeks and every other day for the third. The treatment was then discontinued since the patient had almost entirely recovered. The blood pressures were 110/64 and there was merely a faint trace of albumin in the urine. Her general condition improved remarkably during this time and she left the hospital a few days later. A recent report from her physician is that there has been no return of the nephritis—a period of over five years.

The second case was a man, aged 49, who had been hypertensive and had suffered from chronic nephritis for years. He had an acute exacerbation and became delirious. His urine was loaded with albumin and casts. Following the first injection of oxygen in the back, the delirium began to subside and in a few days disappeared, a corresponding improvement apparently took place in the kidneys as the albumin and casts were decreased. Daily injections were given for two weeks. The patient enjoyed his former usual health for a period of two years, when he suffered another acute exacerbation of the chronic nephritis. Subcutaneous oxygen plus inhalation oxygen at this time proved ineffectual and the patient died.

The third case was a girl, aged 17, who entered the hospital on January 9, 1941. The diagnosis was chronic glomerulonephritis and malignant hypertension of four years' duration. The patient was confined to bed and was mentally apathetic. There had been a gradual rise in the blood urea nitrogen. On January 28, 1941, it was 97 mg., on February 1, 1941, it had risen to 125 mg. After the institution of subcutaneous oxygen therapy the readings were as follows: 102, 81, 74, 85, 91, 133, 145, 148, 158 and 197 on April 8, 1941, when the patient died. The day following the first injection of oxygen the patient's mental condition improved, she had a better appetite and was up and about the ward for several days until the urea nitrogen began to mount. The improvement in her condition continued during the time she regularly received the injections. There was a period of eight days preceding the sharp rise of the urea nitrogen from 91 to 133 during which no injections of oxygen were given and, subsequently, they were ineffectual.

Dyspnea

Cardiac dyspnea, when not too severe, can usually be controlled by three injections of oxygen a week. With some, daily treatment may be required and, in cases of marked dyspnea with a drop in blood pressures due to left-sided heart failure such as occurs after coronary thrombosis, two daily injections may be necessary together with the continuous inhalation of 100 per cent oxygen. The subcutaneous oxygen in these cases will nearly all

be absorbed after twelve hours so that another injection is indicated

The dyspnea due to fibrous changes in the lungs or to emphysema can usually be relieved by the injection of oxygen in the back.

In asthma the oxygen is usually effective after the first injection, but there have been some failures and prolonged treatment may be necessary. Two patients were treated for a month with inhalation and subcutaneous oxygen without effect, but these are the exceptions.

Fatigue

Cases of chronic fatigue due to cardiac disease, low or high blood pressures, or the aftermath of influenza are greatly benefited by the injection of oxygen in the back. The patients feel refreshed on awakening in the morning and their endurance is increased.

Insomnia

Patients suffering from insomnia associated with heart disease, hypertension, or nervous exhaustion have been benefited by the injection of oxygen in the back. The patient usually sleeps well after the first treatment so that hypnotics can often be dispensed with. Once the habit of sleep has been established it may be possible to discontinue the oxygen injections.

A woman, aged 61, had been confined to bed for over a year with congestive heart failure. For ten months she had inhaled 100 per cent oxygen for from four to eight hours a day but was unable to sleep except for short intervals and was troubled with frequent nightmares. Following the first injection of oxygen in the back, she had eight hours of good sleep free from distressing dreams. Her ability to sleep well continued until the time of her death four months later, although the oxygen injections were discontinued after the first month, during which fourteen were given.

Chronic Arthritis

The results in the treatment of chronic arthritis have been variable and in some cases no benefit was obtained after from one to three months' treatment. However, the majority of cases were distinctly benefited both as to relief of pain and increased function. Several months or a year may be required to get the maximum results in these cases.

Apparatus

I prefer to use as light an apparatus as possible so it can be easily transported. It

consists of a "B" cylinder of oxygen, a yoke with needle reducing valve sold by the E-K Medical Gas Company, Bloomfield, New Jersey, a 5-foot rubber tubing to one end of which is attached the barrel of a 2-cc syringe, and 26-gage sterile needles, $\frac{3}{8}$ inch in length. In the office, "D" size oxygen cylinders are used, when empty, the cylinders are refilled from the large Linde Air Products Company cylinders to a pressure of about 1,200 pounds, for the needle valve works better when this pressure is not exceeded.

The Ohio Chemical Company, Cleveland, Ohio, has a reducing gage that indicates tank pressure and the pressure released into the tubing. This is more expensive and is not so easily transported because of its weight and size.

A still more expensive apparatus by which the oxygen injected can be measured is called the Thomas Oxygenator, sold by Perry M. Thomas, 706 McBride Street, Elgin, Illinois. Small needles, which require more pressure to force the oxygen through the hole, cannot be used with this apparatus because the oxygen escapes through the mercury at a given pressure.

Reducing valves or gages may also be purchased from the Cheney Chemical Company, Cleveland, McKesson Technical Appliances Company, Toledo, and the Forreger Company, New York City.

Technic

The best way for anyone contemplating giving oxygen subcutaneously is to practice first on himself. He will then get first-hand information as to how the needle can be inserted with the least pain and how much tension in the tissues will be required before it becomes painful.

The author selects a spot where there are no veins and swabs it over with tincture of iodine. The skin is then pinched tightly and the needle inserted quickly at right angles, usually with the oxygen flowing through the needle. If the oxygen is seen distending the tissues the needle is not in a vein. One should be constantly on the alert, however, since the needle may enter a vein with even slight movement. If several punctures are to be made, as in the back or extremities, the needles are inserted and the oxygen is injected in rotation through the needles. With this method less manipulation is required to spread the oxygen and should the needle get into a vein less oxygen is likely to enter it than if only one needle is used. If blood should be

seen dripping from one of the needles, it does not necessarily mean that oxygen has entered a blood vessel, as the needle may have been caused to enter a vein just as the tubing was being disconnected. If one listens closely, a slight crackling sound will usually be heard as the oxygen spreads in the subcutaneous tissues. When it enters a vein there is a gurgling or a hissing sound which may not be heard because of outside noises.

If the oxygen is injected merely into the region to be treated, it will spread and only a thin layer will be left over the affected area. In order to avoid this the areas above and below must also be filled. For example, in the treatment of a knee the thigh and leg must also be filled. The patient is instructed to rub the oxygen from the leg and thigh toward the knee two or three times on the following day.

In a treatment of a lesion in the foot the needle is inserted above the ankle, and after the leg is filled the oxygen is forced into the foot by compression above the needle. This is usually accomplished with the free hand after the needle has been connected.

If possible it is better not to insert needles in the soles of the feet or palms of the hand since these areas are sensitive.

When a foot is being filled with oxygen there is usually some pain as the oxygen passes over the arch, especially for the first time.

Reactions

The local reactions following the first injections of oxygen vary. There may or may not be any soreness the following day, but the patients are told of this possibility, especially when the oxygen has been injected into the arms or back.

In treating lesions in the head the oxygen should be prevented from entering the ear since earache may result, and when the eyelids are filled with oxygen, although not painful, it obscures vision. When the neck is filled with oxygen, especially for the first time, there is pain on swallowing and a raw sensation in the chest which the patient may diagnose as a chest cold. Sometimes the injection of oxygen in the arms will be painful during

the first night, but usually pain in this region will be immediately relieved and the patients will have a good night's sleep.

While the effects of injecting oxygen into the blood stream are disagreeable, they are not usually alarming unless a large amount has been injected. As a rule there is a dry cough, dyspnea, and a raw sensation in the chest which lasts for about twenty minutes. During this time the face is either flushed or pale and the pulse is slower than normal. These symptoms are overcome more quickly by the inhalation of 100 per cent oxygen.

Conclusions

1 The control of pain and discomfort, either partial or complete, by the subcutaneous injection of oxygen has usually been found possible in the following conditions: acute inflammatory conditions such as arthritis, myositis and neuritis, arterial diseases of the extremities, pruritis ani, coronary thrombosis, dyspnea, chronic fatigue, insomnia, and chronic arthritis.

2 The best results are obtained only when the oxygen is either injected into, or in close proximity to, the pathology. This rule is imperative in most instances.

stool shows considerable quantities of undigested fats—also proteins and starches. Examination of the duodenal contents shows a definite reduction in pancreatic enzymes. Quantitative determination of the lipase and amylase in the blood is an aid in diagnosis.

Tumors of the pancreas may be either cystic or solid. As a rule, cystic tumors give rise to no symptoms unless they become large and interfere with the function of the surrounding structures. Solid tumors of the pancreas are usually malignant and more commonly involve the head of the organ, rapidly extending so as to involve the common bile duct and the regional lymph nodes.

There is no syndrome that is absolutely characteristic of carcinoma of the head of the pancreas. Significant early symptoms are gastrointestinal dysfunction of a nondescript type, loss of weight, progressive anemia, increased nervousness, and a feeling of indefinite apprehension. These symptoms are soon followed by a steadily increasing jaundice. It is often stated that painless jaundice associated with a palpable gallbladder is diagnostic of carcinoma of the head of the pancreas. In actual practice this is often found not to be so. In many cases pain is present and the gallbladder is not always palpable. In the early stages one cannot, as a rule, palpate a tumor mass. The first diagnostic evidence of its presence may be obtained from x-ray examination, which shows a more or less characteristic distortion of the second portion of the duodenum.

Pancreatic calculi, though not common, are not so unusual as formerly supposed. They result apparently from stasis of pancreatic secretion and are soon associated with a chronic pancreatitis. It is difficult to differentiate an attack of pain due to pancreatic lithiasis from one due to gallstones. Examination by means of the x-ray offers the best chance for preoperative diagnosis in these cases. I have purposely dwelt at some length on pancreatic lesions, since they do not come to one's mind so readily as do diseases of the gallbladder or upper part of the gastrointestinal tract.

In acute cholecystitis the inflammatory process may be mild or severe with suppuration. In the mild cases the patient complains of chilly sensations, headache, nausea, at times vomiting, and little or no pain, though there may be a sense of epigastric distress which may be relieved temporarily by vomiting. There is but a moderate elevation of temperature and, at first, some increase of the pulse rate.

During the early stages there may be definite tenderness over the gallbladder region. Any jaundice that develops appears slowly and also fades slowly.

The suppurative type of cholecystitis is accompanied by a severe chill, variable pain, and tenderness. There is a prompt rise in the temperature and pulse rate. Jaundice is apt to develop within forty-eight hours. When chills, fever, and marked jaundice continuing for several days with repeated colicky attacks of pain occur, one must suspect the presence of a stone in the common duct. The abdomen is distended, there is unmistakable muscular rigidity and marked tenderness in the region of the gallbladder, and the liver itself may be enlarged and tender. Perforation of the gallbladder should be considered if there is marked fluctuation of the temperature with a tendency to keep rising, an increase of the pulse rate, diffuse abdominal distention, cyanosis, and intermittent jerky breathing. For a short period following perforation, the patient often experiences some relief from abdominal discomfort, but the interval is brief and not quite so characteristic as that following perforation of a peptic ulcer. Symptoms accompanying perforation, as is true in perforations of other hollow viscera, depend to a considerable degree on whether or not the process is rapidly walled off.

The symptoms of gallbladder colic are fairly well understood and depend on the size, shape, location, and activity of the stone. Our chief interest lies in the necessity of differentiating this type of pain from that of coronary thrombosis, acute pleurisy, and various conditions occurring in the upper part of the abdomen, including pancreatitis (which has already been discussed) and other syndromes that we will discuss later.

In suppurative cholangitis there is an involvement not only of the extrahepatic ducts but also of the intrahepatic radicles and the liver parenchyma. An associated cholelithiasis is usually present. Frequently, the first symptom is a colic. There is considerable prostration, and jaundice appears within a few days and varies in intensity from day to day. The liver becomes enlarged and tender. When the cholangitis is secondary to a cholecystic infection, the gallbladder becomes tender and at times palpable.

Suppurative cholangitis must be differentiated from pyelophlebitis, which frequently follows an acute intra-abdominal infection, such as appendicitis. In pyelophlebitis the jaundice appears late, if at all, and is not inter-

DIFFERENTIAL DIAGNOSIS OF CONDITIONS IN THE UPPER PART OF THE ABDOMEN

MAXIMILIAN A. RAMIREZ, M D, New York City

CHARACTERISTIC pains often hold the key to a correct diagnosis of various conditions in the upper part of the abdomen. They must be evaluated in conjunction with other fundamental data such as the patient's threshold of pain perception, periodicity and degree of occurrence, duration, location, radiation, etc. Various hypotheses have been advanced regarding the anatomic and physiologic concepts of pain production, as well as the grouping of patients in relation to their sensitiveness and reactivity to pain. From a practical clinical standpoint one may distinguish between pain of autonomic and that of somatic cerebrospinal origin. Autonomic or splanchnic or visceral pain results from stimuli traveling along the splanchnic nerves, which constitute the main supply of the gastrointestinal tract, gallbladder, liver, etc. Somatic or parietal pain results from stimuli traveling along afferent somatic nerves supplying the parietal peritoneum.

Visceral pain is obscure, lacks precise location, is usually deep-seated, and may be spasmodic or continuous. Somatic pain, on the other hand, is more apt to be stabbing in character, more superficial, and usually more continuous. It is usually associated with tenderness and rigidity of the abdominal wall. Splanchnic pain results from tension on afferent nerve endings in the muscle wall of the hollow viscera. A good example is the pain seen in early intestinal obstruction, in which the pain may remain unlocalized and abdominal tenderness and rigidity may be absent. Somatic pain is the familiar type encountered in inflammatory lesions involving the parietal peritoneum. This concept of pain is of great practical aid in distinguishing between lesions that give rise to distention of a hollow viscus with exaggerated peristalsis and those that produce parietal peritoneal irritations.

As in all other fields of differential diagnosis, it is absolutely indispensable to obtain a thorough history. This is fundamental. Nevertheless, it is one of the steps most frequently hurried or neglected in making a diagnosis.

In discussing bedside differential diagnosis of syndromes of the upper part of the abdomen, it is my plan to devote special attention to the disorders of the pancreas because pancreatic disease is so often associated with lesions of the stomach, duodenum, liver, and bile passages, and rarely exists as an uncomplicated condition. Besides, this is one organ that is often overlooked. The pancreas lies behind the peritoneum in close contact with two important nerve structures—the celiac plexus and the semilunar ganglia—and is part of the posterior wall of the lesser peritoneal cavity. Acute inflammation of the pancreas is frequently transmitted to the overlying peritoneum, causing a more or less localized peritonitis. Excluding diabetes mellitus, which may be considered as originating in the pancreas, there are comparatively few diseases of the pancreas which are of clinical importance. Acute pancreatic necrosis should be thought of in patients complaining from sudden, severe, agonizing epigastric pain, frequently radiating to the left lumbar region. This left lumbar pain is of special significance in correct diagnosis, as is also tenderness in the epigastrium corresponding to the position of the pancreas and deep-seated tenderness in the left loin. There is profound collapse, rapid feeble heart action, nausea, vomiting, and a peculiar ashy cyanosis. Usually, there is a great deal of muscular rigidity. Occasionally, glycosuria occurs, and examination of the blood and urine may reveal a marked increase in diastase.

Chronic pancreatitis may result from an acute pancreatic necrosis of mild degree or from pancreatic stasis due to calculi, tumors, or fibrous tissue formation. The chief pathologic characteristic is an increase in interstitial connective tissue, with pressure upon, and replacement of, the gland parenchyma. Peripancreatitis is usually associated with a long-standing infection of the biliary tract. It also follows infection of the pancreatic lymphatics, secondary to inflammation of the duodenum or transverse colon.

The symptoms of chronic pancreatitis are obscure, not clear-cut, and closely simulate those of chronic cholecystitis. Patients complain of an indefinite epigastric discomfort, indigestion, and "gas." Examination of the

then down the course of the ureter to the bladder and, perhaps, the testicle. The severity of the pain is in a measure dependent on the size and shape of the stone. Larger calculi that form a mold of the entire pelvis of the kidney often give no sign of their presence and are detected only on radiographic examination.

In perinephric abscess there is frequently a previous history of boils or carbuncles. The onset may be sudden or insidious, depending on whether the condition is acute, subacute, or chronic. The chief diagnostic points are the pain and tenderness over the kidney. Tenderness is maximal in the costovertebral angle, and there is hyperesthesia of the abdominal muscles on the same side. A mass may or may not be palpable in the loin. The abscess may affect and compress the neighboring viscera, causing pleurisy, jaundice, ascites, or edema of the leg. There may be rigors and an intermittent fever of the septic type. The x-ray examination is often of great diagnostic value. It shows an obliteration of the marginal outline of the psoas muscle and a slight scoliosis of the spine, with convexity toward the normal side.

Thrombosis of the splenic vein and infarction of the spleen cause severe acute pain in the upper part of the abdomen. Infarction of the spleen occurs much more often than is clinically recognized. The main symptom is localized pain with tenderness over the somewhat enlarged organ, especially when perisplenitis develops. However, in my experience with splenic infarction, the pain first manifests itself in the epigastrium and later becomes localized over the spleen itself.

Tumors of the spleen, although rare, are also more common than is generally believed. The steadily growing mass may produce pain in the left hypochondrium and may be attended by rapidly developing anemia and emaciation.

Dissecting aneurysm of the aorta, although of comparatively frequent occurrence, is an important and serious condition that must be kept in mind. The patients are more often men than women, usually between the ages of 40 and 70, and the large majority have hypertension. The onset is sudden and not uncommonly brought on by physical exertion, anger, or excitement. The pain is excruciating, being described as tearing, and reaches its maximum intensity very quickly. The site of onset of the pain varies, depending upon the site of the rupture. The pain

quickly spreads from the chest over a wide area, usually downward toward the lower part of the abdomen and legs, but almost never into the arms. Despite the abdominal distribution of the pain, rigidity is usually absent. With the pain there is shock, collapse, and loss of power in the legs, and the circulation in the lower extremities becomes impaired. There is moderate fever and leukocytosis, but the blood pressure is maintained. As a rule, but not always, death occurs rapidly.

An analysis of pain in the upper part of the abdomen would be incomplete without mention of pain referred from outside the abdominal cavity. In contrast to the extreme rigidity of the abdominal muscles in the conditions already described, the stiffness that may occur in thoracic lesions usually is more superficial and more readily overcome. There is little or no tenderness, and relief is often obtained from a degree of pressure that would be unbearable if the abdomen were affected.

Coronary artery disease may give rise to chronic intermittent gastric distress. A careful history is of the greatest assistance. Myocardial infarction is also apt to be confused with an abdominal episode. Often, the pain is in the epigastrium or right upper quadrant and may be associated with nausea, vomiting, and fever. However, there is less or no rigidity or tenderness.

The possibility of coronary occlusion should always be considered in middle-aged or elderly individuals with acute pain in the upper part of the abdomen. Here, differential diagnosis is facilitated by the sudden onset with shock, fall in blood pressure, pulse changes, leukocytosis, increased sedimentation rate, and the development of electrocardiographic changes.

The visceral crises of syphilis may also simulate the pain of organic abdominal disease. Most frequently encountered is the gastric crisis, characterized by recurrent abdominal distress, vomiting, and pain. There is no relationship to the ingestion of food, and the pain may persist for hours or days at a time. After the crisis is past, the patient feels comparatively well and has no gastrointestinal symptoms. Changes in the pupillary and patellar reflexes, as well as other neurologic signs, and a positive serology furnish a key to the correct diagnosis in these cases. It must always be remembered that abdominal distress in patients suffering from cerebrospinal syphilis may be due to ordinary peptic ulcers.

Other possibilities not to be overlooked are

mittent Also, the spleen is more apt to be enlarged

Subphrenic abscess also must be differentiated clinically from a suppurative cholangitis The onset may be sudden with severe epigastric pain, vomiting, and prostration A little later, signs of infection become evident One may find high dullness in the axilla accompanied by marked percussion tenderness An indefinite swelling may appear in the epigastrium The greater number of cases of subphrenic abscess are encountered following suppurative conditions in the abdomen for which operation has been performed A general bacterial infection may give rise to the condition Roentgenologic examination is of great value

Mesenteric thrombosis is fortunately not a common condition, neither is it so rare that it can be completely ignored Any resulting peritonitis is secondary to changes in the intestinal wall supplied by the thrombosed vessel Disorders that favor the blocking of vessels by emboli or thrombi are potential etiologic factors The onset of symptoms is abrupt, with severe generalized colicky pains There is little or no fever, in fact, the temperature may even be subnormal There is marked shock, nausea, and vomiting, as well as signs of peritoneal irritation, the vomitus may be hemorrhagic Some patients have diarrhea with bloody stools, others have no diarrhea but develop a paralytic ileus

Mesenteric thrombosis is most often confused with acute intestinal obstruction, especially so in the presence of distention and constipation It is to be remembered that spasm of a mesenteric artery has been described as giving the same signs as an occlusion Such visceral spasms are more commonly found in patients with generalized arteriosclerosis or hypertension, and the pain may be relieved by vasodilators

Gastric and duodenal ulcers give a fairly characteristic history Perforation of gastric ulcers usually causes localized tenderness in the epigastrium, in the midline, or a little to the left The tenderness is less diffuse than that seen in pancreatitis In considering perforation of peptic ulcers, it is well to remember that an acute perforation may be accompanied by the escape of a considerable amount of gastric or duodenal contents into the peritoneal cavity and that a more chronic type of perforation may result in slow oozing, permitting a thorough and competent protective walling-off

The perforation is usually quite acute, and

in only 5 per cent of the cases does it occur slowly enough to result in a localized limited peritonitis In the so-called chronic form of perforation the ulcer is usually located in the posterior wall, and perigastric abscess formation may result It must not be overlooked that a posterior perforation of the stomach or duodenum may initiate an acute pancreatitis In the acute form of perforation the ulcer is usually located on the anterior wall, and the onset of pain is sudden and extremely severe, well localized at first but soon becoming diffuse With the possible exception of a pancreatic necrosis, it is doubtful whether the pain of any other disorder exceeds that of a perforated gastric ulcer occurring at the height of digestion The abdomen is retracted and assumes a boardlike rigidity Respiration is shallow and, at times, painful Vomiting may occur and the temperature may be subnormal An x-ray examination of the abdomen often shows an accumulation of gas between the liver and diaphragm and, perhaps, also in the general peritoneal cavity

In acute high intestinal obstruction there is an abrupt onset, with intense colicky pain Vomiting is always present and soon takes on a fecal character Collapse occurs early and is more intense the higher the obstruction The pain is usually referred to the middle of the abdomen, but exact localization has no significance In the early stages of acute obstruction the abdomen is not sensitive to pressure Later, when peritonitis develops, pressure tenderness is elicited Distention of the abdomen occurs early and is progressive in character Acute pancreatitis may simulate intestinal obstruction in that it is attended by nausea, vomiting, constipation, and severe abdominal pain But in pancreatic inflammation, the vomiting is usually not fecal and there is early local tenderness

In acute appendicitis, which may be confused with almost any other acute disorder of the abdomen, the pain syndrome has considerable diagnostic significance Appendiceal pain is, in the majority of cases, first described by the patient as a diffuse, deep-seated, epigastric soreness However, in most cases the pain becomes localized in the right lower quadrant in a comparatively short time Nausea, vomiting, fever, and leukocytosis may all be absent at the outset, but the characteristic pain syndrome is a significant sign.

In nephrolithiasis the pain, known as renal colic, is sudden and severe It is an agonizing pain referred to the region of the kidney At first, it radiates across the abdomen and

tient is placed in the Trendelenburg position, a small hernia may escape detection

Hepatic carcinoma, primary or secondary, presents anorexia, loss of weight and strength, vague digestive symptoms, and advancing cachexia. Jaundice, as ascites, occurs in about one-half the cases. Pain may or may not exist, but there is always a sense of heaviness. The liver is enlarged and often tender and frequently presents an irregular surface.

Periarthritis nodosa presents a multiplicity of symptomatology. The principal vessels affected are those of the genitourinary tract (mesenteric and celiac axis), kidney, and heart.

Progressive weight and strength loss, joint and muscle pain, general malaise, progressive anemia, leukocytosis, eosinophilia—as high as 79 per cent having been reported—hypertension, hypertensive arteriosclerotic fundi changes, renal involvement, colicky abdominal pain, and at times the finding of palpable nodules suggest the classic picture, which may be established by biopsy.

Localized peritonitis of the upper part of the abdomen, especially that of gonorrheal origin in the female, may be strongly suspected by history and residual adnexal evidence.

Pancreatic adenoma should be well understood, for a moderate number of these patients is admitted to mental hospitals because of their neurotic, psychotic, or convulsive states.

Bizarre psychic symptoms or convulsions, often associated with digestive symptoms after a period of fasting—as in the morning before breakfast or following vigorous exercise—associated with hypoglycemia commonly below 50 mg per hundred cubic centimeters of blood and rarely as low as 20, with a sugar tolerance curve of the diabetic plateau type but with lower absolute values, are characteristic signs. Speedy recovery from the attack follows intravenous glucose administration. An epinephrine injection during seizure also gives relief and recovery by mobilizing the liver glycogen. The insulin tolerance test is a valuable aid in the recognition of this condition, for, if 5 units of insulin be given intravenously after twelve hours of fasting, two hours later there is no tendency for the blood sugar to reach a normal level if adenoma of the islets is present. Amnesia for the attack is the rule.

Intestinal obstruction is suspected by evidence of colicky pain, progressively increasing during hours, in contradistinction to the severe sudden epigastric pain, at times to the left of the dorsal region, of pancreatitis. Vomiting, eventually fecal, and, very rarely, icterus are common findings. The absence of bile in the vomitus favors pancreatitis and, although active peristal-

sis is common in obstruction, it is absent in pancreatitis.

Obstruction is more common in the young (intussusception, Meckel's diverticulum, appendicitis) and in the aged (carcinoma, strangulated hernia, volvulus), while pancreatitis is more common in men of later middle life. In obstruction, a tumor mass may at times be felt.

Acute pancreatitis, hemorrhagic or nonhemorrhagic, is uncommon before 40 and usually occurs in fat people. There may be mild attacks before the eventual severe one.

A typical attack is characterized by excruciating pain, extending to one or both loins, and profound shock (cold extremities, sweat, weak pulse, subnormal temperature). Reflex vomiting is usually present. Constant epigastric tenderness, with an occasional point of tenderness in the left costovertebral angle close to which area lies the tail of the pancreas, is highly suggestive. Abdominal rigidity may be extreme or, at times, lacking. Jaundice may occur from compression of the common bile duct by the swollen head of the pancreas, but this finding is variable, and even obstructive vomiting may rarely occur from pressure of the swollen pancreatic head upon the duodenum.

If the patient survives the attack ecchymoses in one or both loins, due to extravasated blood having traveled along the retroperitoneal tissue planes, may occur as a greenish yellow or purplish stain in the loins, rarely have the ecchymoses occurred about the navel. This symptom can only appear two or three days following the attack but, when present, is pathognomonic.

A valuable diagnostic aid is the determination of blood amylase. A high blood amylase at the time of an acute attack is strong evidence of pancreatitis, while the absence of such elevation points to an extrapancreatic lesion. Following the acute attack amylase concentration decreases rapidly.

Increased amylase values may occur in some patients suffering from gastritis, gastric and duodenal ulcers, cholecystitis, and other diseases affecting organs in close proximity to the pancreas, but in these conditions the high levels—possibly 3,000 units as against normal values of between 70 and 200 units—are not obtained.

Disease of the appendix or gallbladder can usually be excluded by the eventual lack of tenderness over those areas.

I regret that extreme limitation of time not only prohibits consideration of additional causes of disturbances in the upper part of the abdomen but also precludes more than this superficial consideration of the more nearly characteristic symptoms of the subjects discussed.

intoxication by foods and chemicals and food allergy. A history of dietary indiscretion followed by nausea, vomiting, and diarrhea is, of course, suggestive of intoxication. Chemical poisoning produced by lead or arsenic may also cause generalized abdominal distress. The gums should always be carefully examined for a lead line and the blood for basophilic stippling, and a quantitative determination of the metal itself in the blood and urine should be made. An excess of porphyrin in the urine is often found in lead poisoning.

At times, food sensitivity can produce pain closely resembling that of organic abdominal lesions. Aids to correct diagnosis are a history of known allergic phenomena, relief by the administration of epinephrine, and the presence of eosinophils in the blood.

In the short time at my disposal, I have attempted to correlate some of the more commonly encountered disorders responsible for pain in the upper part of the abdomen. Frequently, I have interpolated the differentiation of the various conditions in the upper part of the abdomen from intrinsic pancreatic lesions, because, as I stated before, I believe that this organ is too often ignored in the clinical diagnosis of diseases of this section. The correct interpretation of pain in the upper part of the abdomen plays an important part in arriving at a correct differential diagnosis.

Discussion

Dr. Henry Craig Fleming, New York City— I compliment Dr. Ramirez upon his enlightening treatment of so vast a subject in the limited period of time allotted for his paper.

The confusing similarity of many dissimilar entities exacts the most cautious consideration of differential criteria. But as this discussion must be limited to a short period, I shall refer but briefly to the more salient symptoms and signs of several conditions that may be confused.

Basal pneumonia, in spite of the downward transmission of pain by way of the intercostal paths and the occasional associated digestive symptoms—the “bilious” pneumonia of bygone years—can usually be recognized by an onset with chill, fever, a “stitch” in the side, cough, often hemoptysis, sputum findings, x-ray, and the absence of deep-seated tenderness over the area of referred pain.

Coronary disease with symptoms expressed to the abdomen may be suspected by persistent, intense substernal pain, possibly preceded by months or years of angina, elevated temperature, ESR and leukocytes, fall in blood pressure, and often, but not invariably, electrocardiographic changes within a few hours. In

this condition, too, deep-seated tenderness is absent.

The crises of tabes should be suspected by pupillary changes, absence of knee jerks, serologic findings, and absence of digestive symptoms following the attack.

The congested liver of congestive cardiac failure need rarely confuse if the history and associated cardiac and pulmonary findings with extremity edema is considered.

Gallbladder disease commonly follows a long history of digestive disturbance, especially gaseous indigestion, “bloating” after meals, and intolerance to fats. The pain varies in intensity and may be felt in the epigastrium and right upper quadrant with radiation toward the right scapula, but tenderness is eventually localized in the right upper quadrant, and x-ray and duodenal drainage may clarify the picture.

Abrupt perforation of gastric or duodenal ulcer is usually agonizing and may be radiated to one or both shoulders, contingent upon the degree of impingement upon the phrenic filaments in the diaphragm by the irritating fluid. Temperature and pulse rise and the rigid abdomen, which may contain not only fluid but also air, may obliterate the normal outline of the liver. In this condition the patient often vomits early but rarely does so again, thus creating an important point of distinction between perforation and obstruction of the bowel. Great thirst, too, is common in perforation—the patient will often drink large quantities in spite of nausea.

Mesenteric embolism and thrombosis is commonly preceded by vegetative endocarditis, phlebitis, or abdominal infection. It commonly occurs in old people with arteriosclerosis and may be suspected in conditions that favor stasis in the portal system. The condition commonly occurs by severe colicky generalized pain. Vomiting occurs in about one-half of the cases and, as a result of infarction, blood may be present in the stool. Leukocytosis and collapse are common.

Diaphragmatic hernia symptoms are often complex because of various structures involved. Esophageal diaphragmatic hernias are usually congenital, but their symptoms may begin at birth or in later life.

Epigastric distress, soon after a meal or following violent exertion, relieved by belching or vomiting should arouse suspicion. But either or both may be prevented by spasm of the diaphragm or cardia as a result of pressure of the herniated portion of the stomach upon the esophagus. And diaphragmatic spasm, by phrenic pressure, may radiate pain to the left shoulder and arm.

In this condition there may be many weeks of freedom from symptoms between spasms. Hemorrhage may occur from membranous erosion. The x-ray is an essential confirmatory procedure of the condition, but, unless the pa-

wandering cells" They showed that these ducts were preformed structures by their constant epithelial lining and *not* incidental tracts caused by infection They demonstrated in every case well-developed ducts that extended from the Morgagni crypts into the submucosa and sometimes into the internal sphincter muscle These same structures were found microscopically in human newborns and even embryos Occasionally, we have been able to demonstrate clearly at the operating table the mouths of these anal ducts macroscopically With good muscular relaxation by turning back the edges of the valves, the mouths of these ducts are frequently seen That they secrete a mucinous lubricant is also occasionally well demonstrated, particularly where there is hypertrophy of the ducts and hypersecretion without infection This is more frequently seen anterior in the anal canal and may be an attempt on the part of nature to assist the flexible and distensible soft tissues of the canal to help absorb the force of the stool from the angulated rectum as it is thrown forward by the posterior well-developed sphincters

The importance of this revealing research is seen comparatively where a small anal duct abscess has occurred In one of our own cases the infection remained localized to the duct until a cryptectomy, or rather a valvectomy, was performed, this incision being carried well outside The operation itself, however, did not take in sufficient field in depth and only served to seal the hitherto well-drawn duct, with the result that after ten days the infection had burrowed down to Hilton's line, out between the external sphincter and fibers of the internal sphincter to form an ischioanal abscess Further quoting from Drs Tucker and Hellwig "We regard the knowledge of these structures of great value in the understanding of the question of inflammatory processes The narrow often branching structures, excretory ducts, without protecting layers of secretion on its epithelial inner surface must be regarded as a natural incubator in case fecal material laden with bacteria finds its way into the opening of these ducts"

Dr Pope,* of Chicago, further confirmed these findings and emphasized his belief that such a medium of infection may result in perianal vascular congestion with subsequent hemorrhoid formation. This may be true in part, but a certainty exists that daily usage of the anorectal canal, together with many cases of

obstipation, predisposes to trauma²⁰ with consequent entrance of low-grade infection directly into the lymphatic tissue in the anorectal zone Weakening of the blood vessel walls with vascular stasis gradually contributes to hemorrhoid formation In our opinion no hemorrhoids removed can be found microscopically free from chronic inflammation Frequently in cryptitis, the adjoining papilla or papillae fall prey to infection, which seems to stimulate the papilla to overgrowth in an attempt to survive functionally These hypertrophied papillae are easily distinguishable (1) because of their situation, the base of which is always at the anorectal line, and (2) because of the general appearance, tusk-shaped with a comparatively broader base than apex, and a dirty gray color The size of a diseased papilla may vary from $\frac{1}{4}$ to 3 inches in length As a result of prolapse through the anal canal it will produce most agonizing pain while in the grasp of the spastic sphincters Upon reclining and relaxation of the musculature, the hypertrophied papilla may return to its interior position with instant relief for the patient

The symptoms of cryptitis are dependent directly upon the duration of the condition and the degree of extension of the inflammation to other associated portions of the anorectal zone, canal, and perianal and perirectal tissues It is infrequent to see a patient with an independent acute or chronic cryptitis We most frequently see the sequelae

In cryptitis, complaint is made of "throbbing in the rectum," a stinging pain on defecation, a fullness or pressure that is constant, or "soreness in the rectum" on sitting Many of these symptoms are common with other anorectal diseases, but by adequate examination they can be readily differentiated By careful palpation clockwise around the anorectal ring, a tender area may be encountered The patient may say "That is the spot," "that is the same feeling I get when my bowels move" Then by visual examination with a fenestrated speculum the field is studied The crypt is readily examined with a probe The amount and extent of inflammation, the effect on adjacent papillae, the presence of pus or internal fistulous openings, the fibrosis or hypertrophy of the valves, in some instances, visualization of the inflamed anal ducts, the association of the inflamed crypt with a chronic ulcer, the presence or absence of a connecting fistulous tract are determined

The diagnosis having been determined, the

CRYPTITIS—PERIANAL AND PERIRECTAL INFECTIONS

F LESLIE SULLIVAN, M D , F A C S , Scotia, New York

CRYPTITIS is an acute or chronic infection of the crypts of Morgagni with the pathologic process originating in the anal ducts opening into the crypts. It is important to have an intimate knowledge of the pertinent facts regarding the anorectum—its susceptibility to focal infection and subsequent pathologic changes particular to the region as a result of these infections. Pennington¹ stated that nearly 85 per cent of all proctologic diseases in or about the anus are caused by an antecedent infection in the crypts of Morgagni. Buie² emphatically writes "Therefore let it be understood that there never has been an anal fistula without a primary internal opening, that opening is always in the anal crypts." Further, Mentzer³ writes "that the crypt has been aptly called 'the biggest little thing in proctology.'" Thus, it may be deduced that the essential nidus for nearly all the infectious diseases in the perianal and anorectal zone is a diseased crypt.

The anorectal line, dentate line, or pectinate line marks the union of the proctodeum and the hind gut. At this line the pouchlike rectum is purse-stringed and, because of a greater circumference than the anal canal, numerous mucosal folds are thrown up, known as the columns of Morgagni, intervening are the crypts of Morgagni.⁴ At the inferior end of these mucosal valleys are the anal valves, which consist of delicate thin layers of transitional stratified epithelium stretched from one column to another. Between the anal valves at the bases of these columns are the anal papillae or "fingers of the rectum." They are small irregularly placed "nubbins" of epithelium, usually about five to eight in number, in the total circumference of the anorectal line. These papilla-form projections contain pacinian corpuscles and as such have tactile sense. They acquaint the individual with the presence of gas or liquid or formed stool within the lowest third of the rectum. Below the anal rectal line this ectodermal lining is stratified squamous epithelium.⁵ The entire anal canal is held firmly closed by the tonic action of the anal musculature, the external and internal sphincters, and the puborectalis portions of the

levator ani inserted into the sphincters at Hilton's line—the White line.

The lymphatic drainage in disease of the valves is important. In the main, most of the drainage is caudal, by the inferior hemorrhoidal plexus. There is, however, some communication with the middle and superior hemorrhoidal plexuses, which accounts for the many submucosal abscesses seen following crypt infections. The highest percentage of infections have a tendency to drain externally from the anorectal zone by several routes which we shall discuss further on.

The rectum and anus also are highly vascular organs, and in general the anus to the anorectal line is bathed with blood by the inferior hemorrhoidal artery, a branch of the internal pudic, the rectum being fed by branches of the superior hemorrhoidal artery from the inferior mesenteric and the middle from the sacral artery.⁶

The venous drainage is similar and there is free communication between the (three) plexuses. So, here in this zone, there is an established communication with the portal system through the superior hemorrhoidal veins and with the inferior vena caval system through the middle and hemorrhoidal veins.

Drs. Tucker and Hellwig,⁷ of Wichita, Kansas, have presented some valuable research material as a result of their studies of the anal crypts. They have shown that the crypt itself is seldom involved but that the infection starts in the anal ducts except in g.c. cases where the crypt is always involved. In their article, "Histopathology of the Anal Crypt," read before the American Proctological Society in 1933, they presented the result of study of 331 hemorrhoids and 89 crypts removed by Dr. Tucker at St. Francis Hospital. I quote from their report "Without exception, our specimens of cryptitis showed the pathologic process confined to the ducts which opened into the crypts of Morgagni. They were either simple tubular ducts or more complex branching structures which extended from the mucosa into the submucosa or muscular layer. In acute infections, the lumen of these ducts was filled with pus cells and the wall was infiltrated with neutrophile leucocytes. In subacute or chronic cases, the wall of these ducts was formed by dense fibrous tissue, infiltrated with lymphocytes, plasma cells, and

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1 1941

wandering cells" They showed that these ducts were preformed structures by their constant epithelial lining and *not* incidental tracts caused by infection. They demonstrated in every case well-developed ducts that extended from the Morgagni crypts into the submucosa and sometimes into the internal sphincter muscle. These same structures were found microscopically in human newborns and even embryos. Occasionally, we have been able to demonstrate clearly at the operating table the mouths of these anal ducts macroscopically. With good muscular relaxation by turning back the edges of the valves, the mouths of these ducts are frequently seen. That they secrete a mucinous lubricant is also occasionally well demonstrated, particularly where there is hypertrophy of the ducts and hypersecretion without infection. This is more frequently seen anterior in the anal canal and may be an attempt on the part of nature to assist the flexible and distensible soft tissues of the canal to help absorb the force of the stool from the angulated rectum as it is thrown forward by the posterior well-developed sphincters.

The importance of this revealing research is seen comparatively where a small anal duct abscess has occurred. In one of our own cases the infection remained localized to the duct until a cryptectomy, or rather a valvectomy, was performed, this incision being carried well outside. The operation itself, however, did not take in sufficient field in depth and only served to seal the hitherto well-draining duct, with the result that after ten days the infection had burrowed down to Hilton's line, out between the external sphincter and fibers of the internal and levator, to form an ischio-rectal abscess. Further quoting from Drs. Tucker and Hellwig: "We regard the knowledge of these structures of great value in the understanding of the question why the anal canal is so frequently the seat of inflammatory processes. The narrow often branching structures, excretory ducts, without protecting layers of secretion on its epithelial inner surface must be regarded as a natural incubator in case fecal material laden with bacteria finds its way into the opening of these ducts."

Dr. Pope,³ of Chicago, further confirmed these findings and emphasized his belief that such a medium of infection may result in perivascular congestion with subsequent hemorrhoid formation. This may be true in part, but a certainty exists that daily usage of the anorectal canal, together with many cases of

obstipation, predisposes to trauma²⁰ with consequent entrance of low-grade infection directly into the lymphatic tissue in the anorectal zone. Weakening of the blood vessel walls with vascular stasis gradually contributes to hemorrhoid formation. In our opinion no hemorrhoids removed can be found microscopically free from chronic inflammation. Frequently in cryptitis, the adjoining papilla or papillae fall prey to infection, which seems to stimulate the papilla to overgrowth in an attempt to survive functionally. These hypertrophied papillae are easily distinguishable (1) because of their situation, the base of which is always at the anorectal line, and (2) because of the general appearance, tusk-shaped with a comparatively broader base than apex, and a dirty gray color. The size of a diseased papilla may vary from $\frac{1}{4}$ to 3 inches in length. As a result of prolapse through the anal canal it will produce most agonizing pain while in the grasp of the spastic sphincters. Upon reclining and relaxation of the musculature, the hypertrophied papilla may return to its interior position with instant relief for the patient.

The symptoms of cryptitis are dependent directly upon the duration of the condition and the degree of extension of the inflammation to other associated portions of the anorectal zone, canal, and perianal and perirectal tissues. It is infrequent to see a patient with an independent acute or chronic cryptitis. We most frequently see the sequelae.

In cryptitis, complaint is made of "throbbing in the rectum," a stinging pain on defecation, a fullness or pressure that is constant, or "soreness in the rectum" on sitting. Many of these symptoms are common with other anorectal diseases, but by adequate examination they can be readily differentiated. By careful palpation clockwise around the anorectal ring, a tender area may be encountered. The patient may say "That is the spot," "that is the same feeling I get when my bowels move." Then by visual examination with a fenestrated speculum the field is studied. The crypt is readily examined with a probe. The amount and extent of inflammation, the effect on adjacent papillae, the presence of pus or internal fistulous openings, the fibrosis or hypertrophy of the valves, in some instances, visualization of the inflamed anal ducts, the association of the inflamed crypt with a chronic ulcer, the presence or absence of a connecting fistulous tract are determined.

crypts of Morgagni. Although this anorectal infection commonly described as cryptitis has been the subject of numerous reports by proctologists, it has not been accredited as being of major importance as a focus." He states, and correctly, that bacteria may pass from the anorectal zone *by the blood stream* to the liver, setting up a periportal hepatitis and cholecystitis, *by way of the lymphatics*, setting up an intrapelvic and intra-abdominal lymphangitis and lymphadenitis and, thence, by mingling of lymph and, by extension, infection of intra-abdominal organs and structures, *by way of the general circulation* to other remote structures through the following means (1) directly at the site of an anorectal infection through the middle or inferior hemorrhoidal veins, (2) by passing through the liver to the general circulation, (3) as lymph collected from the abdomen flowing through the thoracic duct and the left subclavian vein into the general blood stream.

Neurologic, genitourinary, gastrointestinal, and rheumatic symptoms are commonly caused by anorectal disease.^{16,17} Probably the most frequent is low back pain associated with sphincter spasm.¹⁸ Next are reflex gastric symptoms. These may occur not only in acute or chronic infection of the anorectum but also in infected new growths of the rectum. Anorectal disease plays an important role in the hepatic infections as hepatitis and gallbladder disease. Rheumatoid and other types of arthritic patients have shown definite improvement after treatment of cryptitis and associated lesions. By the presence of pain and its effect on the sympathetic and parasympathetic nervous system, many reflex bizarre neurologic conditions may be seen clinically. Genitourinary symptoms are also frequently associated.

Summary

1 Cryptitis is a disease that pathologically is confined not only to the crypts of Morgagni but the anal ducts as well.

2 If this diseased area is not removed in its entirety, certain local complications will inevitably result.

3 Because of the fact that the anorectal zone is a highly vascular and lymphatic terminal center of the circulation, there is necessarily a great absorptive action from any focal area of infection.

4 This focus of infection produces both local and systemic symptoms and diseases.

5 Methods of examination are important, and consequent methods of treatment are

doubly important to eradicate any local or systemic disease so related.

Discussion

Dr. Harry C. Guess, Buffalo, New York.—Discussors of papers are used to augment, elucidate, agree, or disagree with the writer. With regard to Dr. Sullivan's contribution, there are but few points regarding this "big thing"—described by Hirschman as that "little, big thing in proctology"—and by Mentzer as the "biggest, little thing in proctology"—that the writer has not covered. There is nothing to elucidate and only a slight possibility for augmentation. He has made a careful study of anal ducts and an exhaustive search of the literature regarding the condition described.

It is unwise to disagree with an Irishman, and I must agree with his five points of summary.

I must confess that it has not been my experience to view the openings of the anal ducts macroscopically.

Dr. Tucker, a member of the American Proctological Society, has given us a clear description of these structures and has proved that these are not the result of lymphoid tissue retractions as was formerly taught. This contribution has aided materially in the diagnosis and treatment of cryptitis.

treatment of a high percentage of these cases is primarily surgical⁹, in cases of an engorgement of the crypts, with slight redness and no pus formation at the time, office and home treatment will suffice. This consists of cleanliness by irrigations with warm alkaline solutions or normal saline immediately after bowel movements, followed by hot sitz bath for ten to fifteen minutes, plus office irrigations and the use of mild antiseptics. If the infection is more marked, adequate treatment necessitates radical dissection of the crypt and ducts, preferably under caudal anesthesia. As Blaisdell¹⁰ writes "Linear incision by cryptatome or other instrument is useless as recurrence will be inevitable. To perform the dissection expeditiously and with the least discomfort to the patient requires thought and practice." If in doing a cryptectomy sufficient drainage is not established by an excision of the infected anal ducts along with the valve and mucosa, a subcryptic abscess is almost certain to occur where previously a cryptitis was present.

It is conclusive that any crypt infection may result in an abscess. The location of the abscess may be determined by the extent of the infection from the crypt. An abscess is the first stage of a fistula, and careful attention to its surgery frequently prevents further pathologic changes. Many times, however, the amount of edema and induration, the quantity of pus present is so great that correct identification of the offending crypt is futile. The procedure then resolves itself into one or two more stages for the complete removal of all infected tissue, together with correct preservation of muscular action. The infected crypt may be identified by redness or by the presence of chronic granulation tissue.¹¹ It may be scarified or obliterated, but proper dissection of the fistulous tract will lead one to its original source of formation. Mere incision of an abscess is not sufficient to prevent fistula formation. Consequent contraction of the infected tissues gives the fistulous tract, and such an incision provides only an external opening for the tract. It is essential for treatment of an abscess to correctly uncap it and expose it.¹²⁻¹³ All trabeculated pockets must be broken down with the finger, and light iodoform packing placed in the cavity must be removed in twenty-four hours, followed by warm saline irrigations twice a day. It is not advisable to curet it, and ligatures are avoided as much as possible.

In a submucous abscess after the initial incision, an inverted V-shaped portion of the

mucosa is removed between curved Kelly clamps and the edges are tied over properly spaced clamps. Irrigations are done daily by use of a catheter and funnel.

Pelviorectal Abscess—The supralelevator space lies between the levator ani muscles forming the diaphragmatic floor to the pelvis and the peritoneal reflection above.¹³ This space is occupied by loose connective tissue. This connective tissue is reflected over the prostate and the neck of the bladder in the male and the broad ligaments in the female. It is continuous with that of the mesorectum. Infection here may take place in several ways. It may spread upward from a deeply placed complicated anal duct. It may occur as the result of extension of a submucous abscess through the regional lymphatics. It may occur from a primary seminal vesiculitis or prostatitis or by a hematogenous infection from elsewhere in the body.

Several methods of treatment are advocated depending on (1) whether the abscess has broken through the levator into the ischio-rectal fossa, or (2) is a well-localized entity, or (3) is secondary to infection elsewhere, as ruptured appendix, tubo-ovarian abscess, etc.

Those of class 1 should be opened through the ischio-rectal fossa as an ischio-rectal abscess, with the incision carried through and across levator fibers. Those of class 2 or 3 may be done by rectal puncture with insertion of a 1/2-inch drainage tube, which is Hayden's method, or by Husbman's¹⁴ method of opening the retrorectal space and sweeping around the rectum into abscess.

Systemic

It is reasonable that an established nidus of infection is the cause of many systemic diseases. Much stress is laid on focal infection but, through the apparent and persistent neglect to examine the rectum and its prominent anatomical parts carefully, an important field has been overlooked. Because of great absorptive power by a highly vascular and lymphatic field, the rectum and anus assume paramount significance by the presence of a local infection.

Dr. Raile, of Salt Lake City, has cited the fact that cryptitis may be a focus for many major ailments and states¹⁵ "that much significance has been ascribed to teeth, tonsils and other focal infections, but in the opinion of the writer one very frequent and vital infection is frequently overlooked. This infection can be found in the anorectal region in the

crypts of Morgagni Although this anorectal infection commonly described as cryptitis has been the subject of numerous reports by proctologists, it has not been accredited as being of major importance as a focus. He states, and correctly, that bacteria may pass from the anorectal zone *by the blood stream* to the liver, setting up a periportal hepatitis and cholecystitis, *by way of the lymphatics*, setting up an intrapelvic and intra-abdominal lymphangitis and lymphadenitis and, thence, by mingling of lymph and, by extension, infection of intra-abdominal organs and structures, *by way of the general circulation* to other remote structures through the following means (1) directly at the site of an anorectal infection through the middle or inferior hemorrhoidal veins, (2) by passing through the liver to the general circulation, (3) as lymph collected from the abdomen flowing through the thoracic duct and the left subclavian vein into the general blood stream.

Neurologic, genitourinary, gastrointestinal, and rheumatic symptoms are commonly caused by anorectal disease.^{16, 17} Probably the most frequent is low back pain associated with sphincter spasm.¹⁸ Next are reflex gastric symptoms. These may occur not only in acute or chronic infection of the anorectum but also in infected new growths of the rectum. Anorectal disease plays an important role in the hepatic infections as hepatitis and gallbladder disease. Rheumatoid and other types of arthritic patients have shown definite improvement after treatment of cryptitis and associated lesions. By the presence of pain and its effect on the sympathetic and parasympathetic nervous system, many reflex bizarre neurologic conditions may be seen clinically. Genitourinary symptoms are also frequently associated.

Summary

1 Cryptitis is a disease that pathologically is confined not only to the crypts of Morgagni but the anal ducts as well.

2 If this diseased area is not removed in its entirety, certain local complications will inevitably result.

3 Because of the fact that the anorectal zone is a highly vascular and lymphatic terminal center of the circulation, there is necessarily a great absorptive action from any focal area of infection.

4 This focus of infection produces both local and systemic symptoms and diseases.

5 Methods of examination are important, and consequent methods of treatment are

doubly important to eradicate any local or systemic disease so related.

Discussion

Dr Harry C Guess, Buffalo, New York—Discussors of papers are used to augment, elucidate, agree, or disagree with the writer. With regard to Dr Sullivan's contribution, there are but few points regarding this "big thing"—described by Hirschman as that "little, big thing in proctology"—and by Mentzer as the "biggest, little thing in proctology"—that the writer has not covered. There is nothing to elucidate and only a slight possibility for augmentation. He has made a careful study of anal ducts and an exhaustive search of the literature regarding the condition described.

It is unwise to disagree with an Irishman, and I must agree with his five points of summary.

I must confess that it has not been my experience to view the openings of the anal ducts macroscopically.

Dr Tucker, a member of the American Proctological Society, has given us a clear description of these structures and has proved that these are not the result of lymphoid tissue retractions as was formerly taught. This contribution has aided materially in the diagnosis and treatment of cryptitis.

If we accept the statement that 85 per cent of all infections, perirectal and perianal, originate in the crypts, then those causes that comprise the remaining 15 per cent would seem to be relatively infrequent. In my experience this ratio is at variance with Dr Pennington's statement, even though that statement has verification by others in the field of proctology.

We must consider the following sources in the remaining 15 per cent: (1) the source of infection from other organs, (2) injury of the rectal wall without perforation, (3) injury and infection with perforation of the rectal wall, (4) injury and infection of the sebaceous and sweat glands of the perianal skin, (5) pilonidal sinus, (6) diverticula of the rectum, (7) stricture of the rectum, found in lymphopathia venerea, (8) as a sequela to carcinoma, (9) accidents following episiotomy, and (10) sequelae of regional leitis.

Regardless of the source of perianal and perirectal infections, this is one of the most important conditions that presents itself for diagnosis and treatment. It behooves all of the profession to diagnose quickly and correctly the source of, and also the type of, infection.

As has been stated, the perianal and perirectal area is more than richly endowed with arterial, nerve, and lymphatic supply. The large amount of lymphatic, arterial, and venous anastomosis has been amply demonstrated by Mr Ernest Miles and Dr J P Nesselrode. Because of this rich endowment, infection finds its way readily to other areas through both portal and splanchnic systems.

There is one type of infection which most generally originates from the crypts that, I believe, is important, this being the only chance left to augment.

Perianal streptococcic infection was described over sixty years ago as erysipelas, later, as perianal cellulitis. In 1934 Dr Herbert T Hayes reported this condition, with the treatment by x-ray, before the American Proctological Society.

My reason for mentioning this condition is the quick cure without sequelae by radiation, as compared with the incision and drainage methods. The history and symptoms of these cases have been practically the same.

There quickly occurs a swelling of the perianal area, well out on the buttock. The area is a dark red color. There is considerable weeping, and many small blebs are present. Upon pressure, there is a doughy sensation similar to that of the abdomen with tuberculous peritonitis. The affected area is hot. The body temperature is elevated—102 to 104 F, and the pulse rate is rapid and thready. The patient is profoundly toxic.

Generally, incisions of varying lengths and depths have been made in the area affected. These wounds are covered with a necrotic, black membrane. Serous material discharges from the wounds. This is probably due to the venous capillary and lymphatic stasis. No appreciable swelling is felt inside the anus or rectum.

X-ray treatment as recommended by Dr Hayes is given. The results might be described as miraculous—to say the least, marvelous and most gratifying. In forty-eight hours the picture is completely changed. The swelling subsides and the necrotic material disappears. The temperature and pulse rate return to normal. No laudable pus is present and no fistulous tract remains.

The dosage recommended by Dr Hayes is as follows: spark gap, 5 inches, milliamperes, 3, distance, 10 inches, and time, 3 minutes.

My results have been so gratifying and satisfactory that I feel indebted to Dr Hayes, and I offer it that it might, in a small measure, aid in the quicker diagnosis and treatment of this type of infection.

As I said in the beginning, Dr Sullivan has covered his subject most completely. He has shown a most enthusiastic investigation of the literature on this subject, and I have enjoyed having had the privilege of discussing his paper.

JUNIOR SPEAKS

"Tommy, your manners are dreadful. You're a regular little pig at the table," said Father. Silence from Tommy, and Father added, "You know what a pig is, don't you?"

"Yes, Dad," answered Tommy meekly, "It's a hog's little boy."

CIGARETTE SMOKING IN PREGNANCY

F J SCHOENECK, M D , Syracuse, New York

CIGARETTE smoking has become such a common practice that the question of its influence on pregnancy should be carefully studied. There is ample evidence in the literature^{1,2} that nicotine poisoning does have a deleterious effect on pregnancy and reproductive efficiency. However, there are few data on the effect of cigarette smoking as actually practiced.

The physician can almost assume from practical observation that moderate cigarette smoking, i.e., three or four cigarettes per day, has no apparent effect on pregnancy. Certainly, there is no evidence in the literature to the contrary. Are we, however, prepared to say that excessive smoking may not have some influence? In order to throw some light on this subject we have undertaken a series of experiments to demonstrate the influence of cigarette smoking on the offspring of rabbits.

We candidly admit that observations carried out on human beings would be of much greater practical value. However, aside from the difficulties involved in gathering trustworthy data, we must face the fact that were we to produce evidence of deleterious effects on the offspring of smoking mothers, the reaction on these mothers from a psychologic point

of view would be tremendous. We have, therefore, resorted to animal experimentation. We have attempted to produce conditions as similar to actual cigarette smoking as possible.

Methods

Normal, healthy rabbits were bred and the litters raised as controls. The offspring were weaned at twelve weeks. After a rest period the same does were subjected to cigarette smoking for a period of four weeks to acclimate them to this procedure. The smoke from one cigarette was blown into the nostril of the animal by means of a small catheter, each day. Our estimations, according to weight, showed that one cigarette a day for the rabbit was roughly equivalent to twenty cigarettes per day in the human. The gross difference was that the rabbits received all the smoke in a single exposure in contrast to the twenty exposures entailed in smoking that number of cigarettes.

After the period of acclimation, the does were bred to the same bucks that sired the control litters. The does were "smoked" daily throughout pregnancy and lactation. The offspring were not subjected to smoking at any time. The offspring were weighed at weekly intervals from birth until maturity, i.e., 30 weeks. The breeding bucks were not

Symposium on Industrial Health

PERIODIC EXAMINATION

McIVER WOODY, M D , New York City

THE periodic examination is the best means yet devised of detecting disease in its incipient state, and yet during the past twenty years its benefits have reached only a fraction of our population. We doctors are partly to blame because we are trained to care for the sick, not to detect illness in the well. The more closely I study periodic examinations, the more certain I become that the examiner should really be called the "disease detector." Diagnosis plays an important part in medicine, but detecting disease in the apparently healthy person is a challenge to the wits and ability of the ablest medical practitioner.

Physical Examination Not New

The physical examination has an interesting though not lengthy history, but up to the present time it has been all too truly a physical examination. And yet many a healthy man is physically unfitted for work by a diseased mind. Here the Sherlock Holmes which is latent in every man, particularly the physician, should be given free rein. I should not dare make such a statement to a lay audience but before colleagues, trained in medicine, surgery, and psychiatry, I feel quite safe, and I believe your patients would be equally so.

In advocating a wider application of the periodic examination I do not attempt to represent it as something new or revolutionary, for it is neither. It is older than either roentgenology or antiseptic surgery, as a matter of fact, it is older than bacteriology itself. Unfortunately, its growth and development have not been so continuous or so vigorous, for though it has borrowed many techniques that are of the utmost value, the central core of the idea has changed not at all. Our fundamental approach to this problem is much the same as it was eighty years ago. But, if we are to do our full duty by ourselves and our patients we must be alive to the teachings of modern neuropsychiatry. Twenty-five years ago shell shock was a mysterious disease

peculiar to foul and loathsome trench warfare. In its place we now have its counterpart in the fearsome war of nerves, which affects all classes, but which is calmly accepted for what it is, simply because its true nature is understood by all.

In venturing to link the modern concepts of psychosomatic medicine to such a materialistic procedure as the periodic examination, I shall not attempt to revise or improve the somewhat standardized blanks that have been put out by various organizations, but rather do I want to direct your attention for a few minutes to certain misconceptions that, to my way of thinking, have hampered its development, and have militated against a wider application of an idea that is of great potential value.

Granting for the moment that my approach to the whole problem is one-sided, let me, by turning to the past, trace the proposition backward to its beginnings, in the hope that I may be able to find something new to suggest, something worthwhile which has been overlooked. There may be a fork in the road where medical pioneers took the wrong turning, leaving the other path unexplored and its possibilities unutilized. If my quest is in any degree successful the remedy will be self-evident, and its application can safely be left to the profession at large.

Present Need

In troubled times such as these, when the nation is once again preparing for war, it behooves each one of us to keep ourselves in good physical condition. Indeed, as members of the medical profession we have a double responsibility here, for one of our first duties in a war such as this, which bids fair to become a struggle for survival between two opposing civilizations, one of which is entirely dependent on science and learning, is to do what we can to protect and maintain the health of all of our citizens.

There was a time when battles were fought and won by roving bands of mercenaries. Within the memory of most of us, campaigns were waged by conscript armies led by profes-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941

sional soldiers But now all this has been changed by total warfare, which has brought the struggle to the home front, to every man, woman, and child in the population No prosperous businessman can hire a substitute to do his fighting for him, no woman can continue to live peacefully in her home, and no child can grow up ignorant of air raids and high explosives Nowadays, no individual can be forgotten, for each must play his part No longer will it be sufficient for us doctors to examine the soldiers, we must maintain the health of the entire community, rich or poor, sick or well

Views and Procedure—1861

Going back eighty years, let me quote from a lecture given in London, at the Infirmary for Diseases of the Chest, on June 19, 1861,¹ which except for its rather high-flown language might quite well have been written yesterday

"I am perfectly convinced, from my own observation and experience in practice, that patients never think of consulting their doctors till these conditions of unpaired general health have advanced far enough to have been developed into some form of disease that thousands and thousands of people, believing themselves to be in health, are nevertheless undergoing these early, occult, and evasive stages of defect in the physiological state, and that such persons may be considered to be in health, not only by themselves, but by any one accustomed to associate with them, even though it be a physician, and that even if they submit to a medical examination, as ordinarily conducted, they may be declared to be in health."

May I point out the clear implication here that the onset of organic disease is always heralded by "early occult and evasive stages of defect in physiological state" This is an extraordinarily acute statement for the times One might wish that this distinction had been developed further, but in all fairness we must realize that the subject of physiology did not exist when this lecture was delivered At that time Claude Bernard was still without a laboratory in which to work, and yet here we have an unequivocal statement that a "medical examination as ordinarily conducted" may fail to reveal certain disturbances of function that foreshadow organic changes The speaker continued as follows

"I wish then, to propose, as the only means by which to reach the evil and to obtain the good, that there should be instituted as a custom, a system of periodical examination, to which all persons should submit themselves, and to which they should submit their children"

For this auspicious beginning, all honor is due Dobell, but before considering where his conception of the periodic examination fell short, I want to tell you something about the man himself² Horace Benge Dobell was born on New Year's Day, 1828, and died on Washington's Birthday in 1917 During the reign of George IV, one of his early recollections as a child must have been the establishing of Greece as an independent kingdom under the protection of Great Britain, France, and Russia, as an old man of ninety, during the reign of George V, he lived to see Germany begin her campaign of unrestricted submarine warfare In the field of science he saw even greater changes, for he was a contemporary of Charles Darwin, Louis Pasteur, and Joseph Lister and, of course, was greatly influenced by their work His father was a prosperous wine merchant of London, and Sidney Dobell, the poet, was a brother At the age of fourteen he was apprenticed to a surgeon, at seventeen he entered St Bartholomew's Hospital, where he took prizes in surgery and legal medicine At twenty-one he became a member of the Royal College of Surgeons, and at twenty-eight a member of the Royal College of Physicians

After that, he practiced as a consultant, and probably as medical director of one of the early life insurance companies, for when twenty-five he had published an article³ on physical examinations for life insurance, with a list of questions for the guidance of local examiners in making their reports to the home office Finally, in 1859 he was elected physician to the Royal Infirmary for Diseases of the Chest It was there, at the age of thirty-three, that he gave a series of six lectures on the "Germs and Vestiges of Disease," and on the "Prevention of the Invasion and Fatality of Disease by Periodical Examinations" The first word in the title may be somewhat misleading to our ears, because Pasteur had not yet disproved the theory of spontaneous generation and Koch's discovery of the tubercle bacillus was not due for another fifteen years With this background in mind, one can better appreciate the genius of this young consultant who, as a result of his familiarity with the scientific thought of the day, his experience with a life insurance company, and his services in the charity wards of a London hospital for pulmonary tuberculosis, invented the periodic examination and had the courage to advocate its universal application But I, for one, feel that his conception had its limitations, and

that he gave the movement the wrong direction, from which it suffers to this very day. For, like many another consultant, he was guilty of an impersonal attitude toward his patients, and had little interest in them as individuals.

Believing as he did that periodic examinations could be put on what we would now call a "production basis," he drew up an elaborate list of questions or a sort of written examination to be taken by the patient with what help he could get from a senior student or junior physician. And again I quote

"With this schedule, so far filled up, the patient should now appear before an examining physician and surgeon. By them, his personal condition would be ascertained and entered on the schedule. During this time, his secretions would have been under examination by a microscopist and chemist who would fill in their report upon the schedule.

"Finally, with the schedule thus filled up, he should appear before a senior physician and surgeon, by whom the document would be examined, and any further questions asked, if necessary. It would be their business to form an opinion as to the physiological state, the damages sustained, etc., and to direct the hygienic and other precautions suitable to the case. In order to save time, and ensure that these directions should not be forgotten, certain forms of directions should be drawn up, suited to all the principal abnormal physiological states, and damaged conditions, which should be kept printed and numbered. The advising physician and surgeon would only have to mark on the schedule the necessary numbers, and these forms of directions might then be distributed by students, who would thus become familiar with the right methods of preventive treatment in particular cases."

It is only fair to explain that Horace Dobell had his hospital patients in mind when he laid out this rather elaborate and wholly impersonal procedure. But the fact remains that he did not feel it was something for the general practitioner to attempt independently. He put it thus

"There is nothing to prevent general practitioners from undertaking such examinations themselves. But the numerous and uncertain calls upon their time would probably stand in the way, and they would rather entrust the task to consulting men, in which case I think the connection between the two classes of practitioners would be of the most agreeable and advantageous kind."

Practice of Examinations Neglected—Doctors Guilty?

Horace Dobell may have been right, the general practitioner may not be particularly interested in the routine examination of ap-

parently healthy persons, but the fact remains that this idea, as ingenious as it may have been, did not take hold, instead, his suggestion was neglected and forgotten, only to be resurrected after our first World War, when the examination of drafted men revealed an appalling prevalence of physical defects that had gone unrecognized and untreated.

Perhaps we doctors are at fault. It is well to recognize that we tend to be fatalists as far as our own health is concerned. We are tolerant toward the medical student who fancies that he has contracted every dread disease he comes across in his textbooks, but when we graduate and become responsible for the welfare of others, we put away childish things and think of ourselves no longer. We close our eyes to the possibility that we ourselves may not be wholly sound. We ignore fleeting discomfort in the left chest and arm, we seldom test our urine for sugar and we seldom take our blood pressure. Until we come to believe in the periodic examination for ourselves we cannot expect to convince our patients that it is worthwhile for them to be examined at regular intervals. Until we ourselves are willing to be examined annually by some colleague in whose wisdom we have faith and confidence, we cannot speak with real conviction on the subject.

Modern Doctor Checks Body and Mind

Not that I would belittle the mechanistic ideals handed down to us by the nineteenth century, but I would go them one better, for along with the careful findings on kidney disease, I would have the physician so alert, so sensitive to the feelings of his patient that the patient would begin to talk about his life, his ambitions, his sorrows, the trouble with his wife, the vagrant pain in his left chest. Rather than a hundred questions on health, which the patient had to answer before being examined, I would have the modern doctor able to pursue and inventory swiftly all the necessary physical findings of the usual physical examination and would have him do more—I would have him try with gentle friendliness to find out if there was any mental distress which could or should be relieved.

Because we know so much more about the nature of infectious disease, because we are improving aseptic surgery every day, we must increase our knowledge and care of the recesses of the human mind if we intend to do our best for our patients. No longer can we say, even in jest, what they once said in

Vienna, "that the ideal patient had a diagnosis made by Skoda, an operation by Billroth and an autopsy by Roktansky"

Perhaps what I am trying to tell you is that we must abandon the impersonal approach to the periodic examination and get back to the friendly relationship between country doctor and patient before we modern medical men can give a truly comprehensive physical. Not that I would go back in years. Far from it, the x-rays, the blood test, the electrocardiograms are all extremely valuable, but before we moderns can search the mind we must know our patients, have their confidence, their respect, and their complete collaboration

Examination Technic

I believe that the family doctor is the ideal physician to conduct such an examination but, except in a small town, the family doctor has given way to specialist and consultant. In his stead has appeared the company doctor—a physician who is usually on duty where the man works and to whom the man can come for anything from a cut finger to a broken leg or an attack of nerves. The plant doctor is able, in most cases, to give the physical examination year after year and get to know the workers personally. He thus becomes, as the years pass, both friend and health director. Because of this personal factor, a strange phenomenon in a mechanical age, the physical examination as done in large plants is rapidly approaching the ideal, as I see it. I speak from experience here. I have given thousands of physical examinations and I feel they have been successful if, when I go back to a plant, after some years, workers greet me and begin at once to tell me about themselves and their families because, though we may have seen each other for only half an hour a year, they still remember me as an interested friend.

I think that quiet, pleasant surroundings and freedom from rush and bustle make the man who is being examined feel more secure and that, as a result, the examination goes faster. I try to have my patients received promptly, shown into a small room where they may undress in privacy. I try to be ready and waiting when they come into the examining room, as if they truly were private patients. I seem to ignore the printed blank as much as possible because this apparent freedom from routine gives my patient the pleasing impression that he is the one and only person to be getting this particular examination. The more examinations I do, the easier it is to watch the patient with a sort

of all-seeing eye, and as the examination proceeds I try to keep part of my mind free from the actual physical findings and observe the patient's reactions to the things I am doing. Because of this I see things I wouldn't ordinarily see, for a patient's physical symptoms can easily blind one to the mental.

By taking the blood pressure first I am able to observe the patient when he is truly interested, for however mistaken his notions, every layman has ideas on blood pressure, and few are averse to airing them. Some even may ask questions. Usually this is such a good get-acquainted measure that I have to divert their attention to get an accurate reading, particularly if it seems better that they be not frightened completely out of their wits by one which is too high or too low. But this is helpful, too, for I learn much from what will divert him. I do try to be frank with him, so that he will not feel that vital information is being withheld, but we all know that there are times when blunt honesty is not the kindest policy.

Of taking the pulse I make a ritual, and then I get my patient on the scales. Though I have seemed acutely interested only in the things I am doing, I need hardly tell you that these minutes have been practically free time in which to evaluate the man and his behavior. After the height and weight comes the visual acuity test on an eye chart across the room, and now I may stare as closely as I please at the man without seeming unduly curious or presumptuous because his eyes are focused on the eye chart. By now the average patient is telling me things, and because I seem willing and interested they often run on and on. Actually, a few pertinent questions will elicit all sorts of intimate information which is usually given freely and in detail. Those patients who refuse to talk at first often start in suddenly once they are stretched out on a comfortable table and have become relaxed. Two things I try always to remember to omit no essential part of the examination and to let my patient know that what I am doing is for his benefit.

I try never to walk out on a patient until I have given him a clear idea of the result of the examination. If I can give him a clean bill of health I try to make him feel that I am proud and happy to do so. If defects have been brought to light I try to recommend a doctor he will know in town, that there may be a tie between him and the new man, even before he goes to him. A letter of introduction or a telephone call does much to speed the part-

ing patient to the specialist. If an operation is indicated, I have the patient sit down and go into detail with him to mitigate the first sense of shock and to convince him as promptly as I can, as friend and adviser, that operation will be truly beneficial to him. Most patients will go ahead and have a physical defect corrected immediately, once they realize that it will be to their advantage.

No doubt one of the best ways to convince a man of the worth of the physical examination is to advise him to have his children examined on their birthdays as a "health" present. I suggest that when this is done several snapshots be taken for the family album and the weight, height, and physical condition written down, along with the contagious diseases, if any, that the child has had during the year. In this way a simple, worthwhile record of the child—his physical and mental health during each year of his life—is assured. Most men immediately perceive the benefit this will be to their children and usually remark, "Gee, I wish I'd had such a record. I never did know what I've had besides measles and whooping cough, and as far as a birth certificate's concerned, I had to get my uncle to swear I was even born."

Because this record is not started at the age of one is no reason not to start. Even if a man is thirty-three, he will realize that with half a lifetime yet to live such a record may prove extremely valuable to him in later years.

Before their first physical examination I often found hard-boiled scoffers and skeptics, but after I have examined a man for two or three years, given him good advice about himself, shown him where his thinking was getting a little off the right track I have found that I could safely stake my reputation on the dependability of my findings.

Psychosomatic Medicine An Adjunct to the Periodic Examination

In closing, I hope I have convinced you that it is the humanness of the man giving the examination that counts as much as his medical skill. If I have also convinced you that it is this humanness that will make it possible for general practitioner or plant physician actually to practice psychosomatic medicine in the physical examination I will have succeeded in leaving with you the germ of what I believe is new in the periodic examination. If I have also convinced you that if a physical examination is good for the patient it is equally good for the doctor—I will be truly surprised!

Discussion

Dr R. C. Kimball, *Brooklyn*—Dr Woody, I think, has stressed periodic physical examinations by citing from past experiences and outlining his approach to this problem. May I emphasize that the purpose of periodic physical examinations is the prevention of illness or disease. There are two phases of this prevention: education of the laity to prevention and the examination for the early detection of disease.

I agree with Dr Woody that we as doctors are partly to blame for not having made greater advances in periodic physical examinations in that we have not succeeded in educating the laity on this problem. There are two reasons why this has not occurred. We have not been able to erase from the mind of the "oldster" the still existing superstition regarding illness. However, among the "youngsters," public schools and colleges have done much. The other reason has been somewhat the fault of the doctor himself in that he fostered this superstition and fear by being uncommunicative and mysterious regarding the patient's illness. After he has made his study—history, physical examination, laboratory tests—and established his diagnosis, he proceeds directly to the point of telling the patient only what to do to rid himself of his disease.

We must go beyond the point that pain and cosmetic reasons cause the laity to seek medical attention. We can do this by suggesting to our patients that a "stitch in time may save nine," and that you would much prefer to see them yearly for the purpose of prevention of illness rather than care for them during an acute illness. You might go so far as to suggest that you will be glad to send yearly reminders, such as the dentists do.

Half of the practice of medicine is salesmanship—establishing a definite confidence in the patient toward you, not so much as to the powers as a doctor, as much as a confidant or advisor. Don't be abrupt, be willing to talk with him, not to him, be willing to listen and share with him his burden, whether it be himself or some member of his family.

I agree with Dr Woody establish some definite routine, a routine that you have found to be impressive. Stick to it, develop it, improve on it, and establish it to such an extent that you are unaware of it but the patient is not—that when the patient is with you, you are giving him your undivided attention and your sole concentration, he commands your one thought. When you have done this, regular periodic physical examinations will become the rule.

The stress placed on the mental aspect was

gratifying Remember the old saying—"that the practice of medicine is 90 per cent from the neck up" Of course, this is not true but it does say that you must sell yourself, that confidence must

be established, that the doctor has to be more than a physician, that he must be a "Tribal Medicine Man,"—a man who not only understands you but knows his medicine

NEW MEDICAL OPPORTUNITIES IN NATIONAL DEFENSE INDUSTRIES

C D SELBY, M D, Detroit

SINCE its organization in December, 1937, the Council on Industrial Health of the American Medical Association has foreseen great opportunities for general medical practitioners in service to industry beyond the care of occupational injuries and diseases and has endeavored to prepare the profession to meet these opportunities in a creditable fashion

Among the early discoveries were these amazing facts

1 Medical service in industry is predominantly in the hands of general medical practitioners.

2 Those who specialize in industrial medicine are relatively few, being employed mostly in large industrial establishments and engaged chiefly in applying measures for the prevention of occupational diseases and the promotion of health

3 Opportunities of like nature can be found in small manufacturing establishments as well as large and are, therefore, available to the general medical practitioners

4 These have, to a considerable degree, failed to see this opportunity, having limited their industrial activities to the treatment of occupational injuries and diseases

Realizing the importance of manufacturing in relation to national defense, the health of the workers in relation to defense manufacturing, and the medical profession in relation to the health of the workers, the Council of National Defense of the Federal Government has taken the following action

With the approval of the President it has designated the Federal Security Administrator as coordinator of all health, medical, welfare, and related defense activities He is authorized, with the approval of the President, to appoint such advisory committees and subcommittees as he may find necessary or desirable to assist him in his coordinating duties

One of such committees thus appointed is known as the Subcommittee on Industrial Health and Medicine and it functions through the Health and Medical Committee—consisting of Dr Irvin Abell, the three surgeons general, and the secretary of the National Research Council—as an adviser to the coordinator in industrial health and medical activities relating to national defense

This Committee is pursuing its work of coordinating with these two objectives in view (a) the integration of all federal, state, and volunteer organizations—such as the Council on Industrial Health, the American Medical Association, the American Association of Industrial Physicians and Surgeons, the American Industrial Hygiene Association, and the Section on Industrial Hygiene of the American Public Health Association—to the end that an organized program in the field of industrial health can be applied to the national defense industries, and (b) the promotion of a demand for more complete health service in the small, as well as large, defense industries

The latter points directly toward the general medical practitioners who serve industries either on a part-time basis or on call

Two means of health protection are essential in the defense industries

1 Control of manufacturing conditions known, and thought to have, adverse effects upon health—this is known as "industrial hygiene engineering"

2 Medical service for the workers in the shape of physical examinations, safe placement, consultations in regard to health, and the care of occupational injuries and diseases all of which are collectively known as "industrial medicine"

"Industrial hygiene" and "industrial medicine" jointly comprise the science of industrial health

It is particularly in relation to industrial medicine that the new medical opportunities are found in the national defense industries Openings for full-time industrial doctors are

Read by invitation at the Annual Meeting of the Medical Society of the State of New York Buffalo, New York, April 30 1941

From the General Motors Corporation Detroit

increasing, and already there appears to be a shortage of qualified men brought on, no doubt, by military activities. The Council on Industrial Health of the A.M.A. proposes to assist in this emergency by registering all physicians who wish to take up industrial medicine as a career, regardless of training or lack of training and experience. The training will have to come later, whether in service or by special arrangements yet to be completed. Those who might be interested are requested to address Dr. C. M. Peterson, secretary of the Council on Industrial Health, at 535 North Dearborn Street, Chicago. The demand for part-time doctors who are usually general medical practitioners is also growing, and it is here that those who serve industry on a call basis are most likely to find their opportunities if they are prepared to do something more than treat occupational injuries and diseases.

This type of industrial service need not interfere greatly with private practice. There is nothing new about it except that in the past it has usually not included physical examinations, safe placement of applicants for work, etc., being limited to the care of compensation cases. As industry is now expecting more than this and as the Subcommittee on Industrial Health and Medicine is urging more upon industry, the Council on Industrial Health recommends that county and state medical societies prepare themselves to give local post-graduate instruction to those physicians who are interested, especially those who are already doing part-time work on a limited scale. An outline of such a course can be obtained by application to the secretary of the Council on Industrial Health, and no doubt there are enough able industrial physicians to put it on in an attractive and interesting manner.

A course of this nature will prepare to a considerable extent the general medical practitioners to render a service in industry which compares favorably with that of the full-time service of large establishments.

In order that there may be an adequate conception of medical service in industry, the following are offered as principles governing practice of that character:

1. Prevention of disease or injury in industry by establishing proper medical supervision over industrial materials, processes, environments, and workers.
2. Health conservation of workers through physical supervision and education.
3. Medical and surgical care to restore health and earning capacity as promptly as

possible following industrial accident or disease.

The duties of the physician in industry are sketched as follows:

Prevention—The physician should acquaint himself by regular inspection with all materials and processes used in the working environment over which he has supervision to the end that he may recommend appropriate protection of employees from conditions actually or potentially harmful.

Industrial Physical Examination—Pre-employment physical examinations should be complete. They should be used only for the purpose of assisting the employer to provide safe and healthful employment for the prospective workman.

Periodic physical examinations should be complete enough to provide positive health protection for the workmen and to safeguard the public welfare. The frequency of such physical examinations must be determined by the physician in accordance with specific requirements.

In the interest of completeness and uniformity, physical examination forms are recommended. Personal records of this character are confidential and should always be kept in the custody of the medical department. Access to these records should be granted only upon request or consent of the examinee.

The examining physician should acquaint the examinee with the results of all examinations and take steps to refer all conditions requiring correction to the physician of the worker's choice.

Health Education—The plant physician should take advantage of all opportunities for beneficial instruction of the workmen in hygienic living both in and out of the industrial environment.

Medical and Surgical Care (1) *Treatment of compensable injuries and diseases*—The disabled worker should be free to choose his physician from all those competent to supply the required services. Competence should be determined by professional standards only.

(2) *Treatment of noncompensable injuries and diseases*—The treatment of injuries or diseases not industrially induced is a function of private medical practice from which the industrial physician should abstain except in the case of

(A) *Minor ailments*—The physician in industry may treat minor physical disorders which temporarily interfere with an em-

ployee's comfort or ability to complete a shift, and for the relief of which he may need immediate medical attention

(B) *First aid for urgent sickness*—The physician in industry should employ such measures as the emergency dictates in all cases of urgent sickness occurring during working hours upon the working premises until such time as prompt notification of the family physician relieves him of further responsibility

(C) *Rehabilitation after sickness and injury*—The physician in industry can properly assume responsibility for those phases of rehabilitation after disability, industrially induced or otherwise, which progress best under controlled working conditions

The general relationships of the physician in industry are as follows

With the Employer—Adequate industrial medical supervision requires full- or part-time service of physicians depending upon size of plant, location, prevalence of dangerous health exposures, and other considerations. In every case a physician's relation to industry is improved if he does not solicit the appointment. Written contracts between a physician and an employer are usually unnecessary. If a contract seems desirable a copy should be filed with the local county medical society.

With the Employee—Adequate industrial health conservation depends upon cooperation from workmen. They must, therefore, receive the same courtesy and professional honesty as do private patients.

Industrial physicians should not treat employees for noncompensable disability or assume any obligation contractual or otherwise for the diagnosis and treatment of dependents of employees or members of plant administrative or advisory staffs except in the absence of conveniently accessible independent private facilities.

With Industrial Nurses and Nonprofessional Assistants—Industrial physicians should be responsible for the proper instruction and subsequent activities of nurses and other assistants. Their functions should be described in clear and comprehensive written orders posted in the medical department. There should be no delegation of services requiring expert medical attention.

With Consultants—Assistance should be asked of consultants in industrial medicine, surgery, hygiene, or in the clinical specialties whenever the interests of the workmen demand it.

In the control of working environments the

same consulting arrangements should be entered into with industrial hygienists and safety engineers.

With Official Health Agencies—The physician in industry should consider himself as a deputy health officer in practice if not in fact. Assistance from bureaus of industrial hygiene in state and city governments to control healthful working conditions is available. In return, the industrial physician should cooperate by accumulating and reporting compilations of dependable data on the relation of occupation to morbidity and mortality.

The foregoing outline of medical service in industry is conceived in the sole purpose of giving the employed population the best possible health protection consistent with (1) the purpose of industry, which is manufacturing, (2) the employer's responsibilities as fixed by law, which are the prevention and care of, and compensation for, occupational injuries and diseases, (3) the duties and objectives of official and nonofficial health agencies, which are distinctively in the field of preventive medicine, and (4) the employee's rights as to free choice of physician in the care of sickness and injuries not legally related to occupation.

This conception offers a broader scope to industrial medicine than is generally understood and appreciated by physicians in private practice, yet it recognizes their rights as private physicians as well as those of other parties concerned in the general problem of protecting the health of the working people.

Discussion

Dr R. C. Kimball, *Brooklyn*—Extensive discussion of Dr Selby's paper is unnecessary since he has given a clear, concise statement of existing facts. These are (1) what steps the Federal Government has taken to intergrade the present medical and hygienic agencies into a working unit to oversee or supervise the health of the defense worker, (2) that there is room in this defense industrial medical setup for more and more physicians, with instruction for those inexperienced in industrial medicine, and (3) the part the physician should and will play in defense industry.

I wish to emphasize another fact not discussed here—that is, both the Army and Navy are cognizant of the need of coordination and cooperation on their part with this program. They must depend upon adequate war material being delivered in a steady flow to them by these defense industries in order to build our defense efficiently as well as rapidly. They realize as much as we the need for safe speed, that this war is being operated on a time schedule and, therefore, early delivery depends upon safe and

healthful working conditions and, above all, the continued good health of every worker

There is yet another fact that I think should be called to our attention—that is, once this system comes into full operation it will have such momentum that it will carry over to the near defense industries and, finally, into all industry, particularly so if this war lasts a number

of years. This is brought up not to cloud the present issue but to clarify it, since we must at the same time carry on long-term thinking about our medical problems as well as short term present-need thinking. In other words, are we and will we be prepared from a medical standpoint to meet this demand with a concrete positive answer for the benefit of both medicine and society?

INDUSTRIAL HEALTH AND THE GENERAL PRACTITIONER

LEVERETT D BRISTOL, M D, Dr P H, New York City

IN NO field of medicine, public health, or allied sciences have more rapid or significant developments recently taken place than in that of industrial health. The terminology and objectives of today are different from those of yesterday. A short time ago one spoke only of occupational diseases and accidents. Now one speaks of industrial health, including the prevention and control of syphilis as well as of silicosis, of tuberculosis as well as of traumatic neurosis, of pneumonia as well as of plumbism, of the common cold as well as of carbon-monoxide poisoning, of heart disease as well as of heat exhaustion, and of off-duty accidents as well as of industrial injuries. Industrial health implies not only that health should be promoted in industry but that industry should take a leading part in community health conservation.

The vast majority of workers are employed by smaller plants and business concerns, most of which have little or no facilities for adequate programs of industrial health. For smaller business concerns much of the health service and medical work ultimately must be made available either (a) by groups of these smaller concerns working together as units through some joint plan of centralization—as, for example, those in one building or trade group or in a restricted locality—on the basis of pooling of costs for medical, nursing, and other assistance required, or (b) by local community agencies such as official health or labor departments, voluntary health agencies, university institutes of industrial hygiene, or organized local medical societies or groups of physicians. In this latter connection the general practitioners of medicine would have important functions to perform.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

Health director American Telephone and Telegraph Company

The science and art of industrial health like the worker whose mental and physical fitness it serves to protect and promote, have evolved through periods of infancy, childhood, and adolescence into vigorous adult life. It may be of interest to emphasize the changing characteristics of organized industrial health promotion through these four periods and to note the relationship of the practitioner of medicine to this development.

I Development Periods of Industrial Health

(1) *Infancy—Traumatic Surgery*—A little over twenty-five years ago, interest in the health of workers in various industries of the United States was aroused, particularly by the need for surgical care or treatment of industrial accidental injuries and in the newer compensation cases associated therewith. Traumatic surgery rapidly developed as a specialty, and the company surgeon became the first central figure in the field of early industrial medicine.

(2) *Childhood—Accident Prevention*—The next stage in the development of industrial health as we know it today was that of accident prevention. To the credit of numerous lay representatives of industry and such organizations as national, state, and local safety councils, excellent results followed the inauguration of industrial safety programs and practices. The key person of this period has been the safety engineer or supervisor. However, there are important medical aspects of accident control, and the practicing physician working in the industrial field has much he may contribute to the solution of this problem of accident prevention and safety. The physician's chief function during this period has been in the teaching and practice of first aid, which is one of the most important adjuncts of safety work.

(3) *Adolescence—Occupational Disease Control*—The third stage in our well-rounded development of industrial health in this country has been associated with many significant discoveries in relation to occupational diseases and in the establishment of procedures for their control. The general practitioner of medicine has long had knowledge of the diagnosis and treatment of these conditions, but he has had to depend to a considerable extent on the chemist, the toxicologist, the laboratory expert, the engineer, or the so-called industrial hygienist for much of the recent progress in prevention and the hygiene of the industrial working environment.

(4) *Adult Life—Positive Health Promotion and Sickness Prevention*—While these four periods in the development of organized industrial health work are not mutually exclusive—inasmuch as each period partakes somewhat, and makes use of, the techniques of the period that has gone before—the present stage of industrial health activities involves positive health promotion and education and sickness and accident prevention on a broad scale. Attention must be given not only to occupational injuries and diseases but also to the prevention and control of all nonoccupational sickness and accidents, with special reference to the common diseases of the upper part of the respiratory tract, tuberculosis, syphilis, heart disease, diabetes, appendicitis, and arthritis, as well as so-called off-duty accidents in the home and on the public highway. In this complete development of the modern industrial health program the general practitioner will have an increasingly important part to play.

Gradually weaving her way into the very warp and woof of industrial health, the industrial nurse, particularly in this present period, has come to occupy an important place in what might be called the industrial professional triumvirate along with the physician and the hygienist.

II. The Physician in Industry

Industrial physicians may be classified into three groups based on the amount of time given to work, viz (a) those on full time, (b) those on part time, and (c) those on call for special emergency services.

The full-time industrial physician usually is a member of the company medical department staff on a salaried basis, with special training and experience in industrial medicine. He must assume duties not only as a consult-

ing physician or surgeon but also more or less as the health officer of the company, applying all of the known principles of preventive medicine and industrial hygiene to the employee group. In some of the larger companies various of these functions may be separated under several physicians.

Part-time physicians give shorter or longer periods of time to services in one or more company plants. They usually are paid a stated sum per week, month, or year by the company in question according to the amount of time given. In general, their activities are associated with physical examinations, case work, and special problems having to do with compensation and other medicolegal matters.

Physicians on call serve only on special request. They and the part-time plant physicians are the usual community practitioners and specialists without any particular training or experience in the medical or health problems of industry. Up to the present time most of the smaller industrial plants are served by these general practitioners, and industry is slowly making more and more use of such medical knowledge and service.

In no sense should the so-called industrial physician be a competitor of the general practitioner in the community. All members of the medical profession, including the general practitioners, the full-time and part-time industrial physicians, and the public health officers, should work together for the benefit of all concerned and for the better promotion of industrial health.

(1) *The General Practitioner and His Functions*—Without attempting to go into detail as to the functions or duties of the general practitioner in relation to industrial health, it may be stated that his chief obligations and opportunities are as follows:

(a) To promote industrial health as an important function in the larger field of public health.

(b) To maintain joint responsibilities to employers, employees, and official governmental agencies concerned with industrial health.

(c) To recognize and report occupational diseases and all other diseases required by law to be reported.

(d) To encourage management and labor to see the value of industrial health conservation.

(e) To educate and advise employed persons regarding their health.

(f) To make pre-employment or preplacement and other physical examinations that

may be required and to assist in the follow-up of cases needing correction of impairments

(g) To guide employed individuals to adequate medical, surgical, or specialized treatment facilities where necessary

(h) To assist in matters pertaining to general sanitation of the plant and to have knowledge of the potentially toxic materials or disease-producing processes used in any organization that he may serve

(i) To have a general knowledge of employee and industrial relations and of personnel practices and facilities

(j) To be versed in the handling of traumatic surgical emergencies and in workmen's compensation laws

(k) To work in harmonious and ethical relations with fellow practitioners and industrial physicians

(*ℓ*). *The General Practitioner and His Leadership*—The most essential requirement for the ultimate success of industrial health administration is a sympathetic cooperation between the private practitioners of medicine and surgery and the industrial authorities, including lay and medical leaders of private industry and governmental agencies. It may be stated without much fear of contradiction that the general practitioner of medicine, whether he is giving a small amount of time directly to industrial work or serving industry indirectly as the private physician to employed persons, is potentially the most important unit in industrial health work. On him, at present, largely rests the success or failure of such work, particularly for the smaller industries. While much may be said in favor of the thesis that industrial health service is not a medical monopoly, it must be admitted that it would be more difficult to carry on successful industrial health work without the physician than without the other specialists who make up the so-called industrial health profession.

Special studies of the causes of industrial absenteeism indicate an average of a little less than one-half day lost time per person per year from industrial accidents, a little over one-half day per person per year from non-industrial accidents, and over eight days per person per year from the ordinary run of sickness. Only 10 per cent of the lost time of employees is due, in general, to accidents and occupational diseases that are compensable. These facts emphasize the problems for immediate attack and also suggest the large part that the general practitioner of medicine

should have in their solution in cooperation with industrial management and workers.

(*§*) *The General Practitioner and National Defense*—Industrial health work should be a strong arm in national defense, particularly in the preservation of expert workers and assisting in the development of additional skilled workers. Reducing lost time due to occupational and nonoccupational illness and accidents and cutting down excessive exposure to injurious materials are parts of the industrial health program which will be conducive to maximum national effectiveness and production. It is particularly necessary that studies be made to determine unfavorable environmental factors in the production of war equipment and munitions. As a matter of fact, the needs of national defense require a strengthening and broadening of the entire industrial health program all along the line, from private industry to local, state, and federal jurisdictions. In this significant period of rearmament during which our chief defense will be our industrial skill, let us be sure that we place first on our list the health and safety conservation of our industrial workers. In this connection the general practitioners of medicine will be called upon for an ever increasing leadership.

Man power is the greatest need both of industrial production and national defense. Adequate man power is dependent upon the highest type of mental and physical fitness. The speed-up of production and manufacture, the development of new materials and methods, the increased employment of new workers unused to the hazards of industry will require new industrial health routines and regulations, more intensive study and research in the field of occupational diseases and industrial poisons, and the extension and improvement of all health and safety education. To speed the work but to spare the worker should be our aim.

Industrial health preparedness in the United States is only one phase of a general health preparedness program, although from the standpoint of national defense industrial health undoubtedly should command first attention since it involves our adult civilian population of productive workers and the enlisted land, sea, and air forces of the country, upon all of which successful national defense in times of emergency must depend. Industrial medicine, even in a national defense program, must be preventive and educational, as well as reparative, reconstructive, and curative. General practitioners will have impor-

tant parts to play in the national defense program both from the standpoints of (a) the physical and mental fitness of civilian workers and enlisted forces, and (b) the safety and healthfulness of working and training environments

According to recent data obtained by the American Medical Association, while upward of 10,000 carry on some industrial activity, there are probably less than 5,000 out of a total of over 175,000 physicians canvassed in the United States who can qualify as competent in the field of industrial medicine. Only about 1,300 could be listed as actual specialists or experts. This emphasizes one of the chief unmet needs in connection with the national defense emergency and calls not only for more and better graduate and postgraduate instruction on industrial health in our medical schools but also for the immediate organization of short industrial health courses in strategic training centers throughout the United States, as well as "on-the-job" refresher courses by local medical societies.

III Industrial Health and the Medical Society

The Medical Society of the State of New York for some years has had a Section on Industrial Medicine and Surgery, active, particularly, in connection with the annual meeting of the Society. In addition, there is a standing Committee on Industrial Dermatozoses and one on Workmen's Compensation. In conformity with the recent trend in many states, it is respectfully suggested that the Society create a standing Committee on Industrial Health and plan the scope of its activities in cooperation with the Council on Industrial Health of the American Medical Association and other state committees of like nature. Moreover, in those counties made up of large industrial populations, it would be desirable to encourage the establishment of Committees on Industrial Health in county medical societies where this has not already been done. It is here that most of the important industrial health problems and services must be worked out in cooperation with local community agencies, public and private.

The Council on Industrial Health of the American Medical Association has developed a guide to committees on industrial health in state medical societies, and it includes the following suggested objectives

- 1 To train industry and labor to the value of industrial health conservation

- 2 To develop a clear understanding of the proper scope and functions of industrial medicine and to clarify relationships between private and industrial practice

- 3 To keep the medical profession informed about all accepted methods for reducing the frequency and severity of industrially induced disability

- 4 To elevate medical relations under workmen's compensation

- 5 To scrutinize all legislation affecting the health of industrial workers

- 6 To improve relationships between medicine and insurance

- 7 To establish working relationships with all agencies in the state interested in industrial health

- 8 To arrange for the adoption of similar activities through cooperating committees in the medical societies of the industrial counties

To accomplish these objectives it has been recommended by the Council that the personnel of the state committees include representation from

- 1 Private practice
- 2 Industrial medical practice
- 3 Medical representation, if such exists, from each of the following
 - (a) State bureau of industrial hygiene.
 - (b) State workmen's compensation agency
 - (c) The medical faculties in the state.
 - (d) Industrial insurance company

A bulletin has been developed by the Council on Industrial Health to permit interchange of ideas between committees of the state societies and as a means of estimating progress.

It is my privilege, as a member both of this Society and of the Industrial Health Council of the American Medical Association, to offer on behalf of the Council every possible assistance in furthering the interests of the Medical Society of the State of New York and the general medical practitioners of this state as they relate to the increasingly important subject of industrial health.

Discussion

Dr R. C. Kimball, Brooklyn—Dr Bristol has expressed in a most enlightening way the relationship between the worker and his family doctor. Today, every family doctor is, in reality, an industrial physician, whether employed by industry or employed by the worker. This is true because most of the larger industries have medical de-

partments that control the sickness benefits that the worker receives and, as such, are in constant contact with the general practitioner. This is an indirect relationship but it is becoming more direct each year. The industrial physician is actually "looked up to" by the workers because he has shown them to what extent he may benefit them, and he is in reality a "go-between" between his company and the workers. He takes up the varying problems that confront the industry—the working conditions—partially guides the safety programs, even extends his helping hand into the home of the worker through advice and through programs of illness preventions, and may even plan with employers on health problems.

We speak of industrial health not because it is apart from the general health but because as industrial physicians we have the worker under our control for at least eight hours a day. This amount of time gives us the opportunity to work with him and for him not only because of accidents but all the other illnesses that may overtake him. Industrial Health is only a portion of the general health program, and due to the changing social order we are able to do today what we could not do forty years ago. Medicine, as it should, must follow in the wake of all social changes or reforms. It must, however, keep up with these changes, and the industrial physician can guide and aid medicine in these changing times. Dr Bristol's suggestion of creating a standing committee on industrial health should be acted upon without hesitation. Dr Bristol has listed eight definite reasons why this committee should be formed, and with the defense program going into high gear we, as industrial physicians, should be ready to answer the call that is becoming more insistent each day.

Discussion of Symposium

Dr Irving Gray, *Brooklyn*—The appeal issued by Dr Woody for the periodic health examination is a reiteration of what the leaders in medicine have long been advocating.

From the standpoint of the laity, and from the point of view of the physician the periodic health examination is highly desirable. The profession has long recognized that diseases such as hypertension and associated cardiovascular phenomena, diabetes, and nephritis may exist for months and years before symptoms or complications arise which bring the patient to the doctor. Many of the complications of these "silent diseases" are irreversible and medical science can accomplish little when the disease is treated at a late date. The reduction of the mortality rate from carcinoma depends primarily upon early diagnosis.

The periodic health examination is essential if early diagnosis is to be made. It is not uncommon among those interested in industrial medicine to see individuals with active pulmonary tuberculosis engaged in arduous physical activi-

ties. These individuals have no symptoms and continue in their work until some accident occurs and the question of compensation arises. The underlying disease is then revealed.

Experience has shown that there is no parallelism between pathologic findings and clinical symptoms. The autopsy frequently discloses findings entirely unexpected and unrelated to the cause of death and unassociated with any clinical symptoms. The corollary is, of course, correct. There are patients with many complaints who have no organic disease.

The logical answer to the entire question is the periodic health examination. This can only be achieved by intensive education of the public.

Dr Selby has drawn attention to the new medical opportunities offered in National Defense Industries. The presentation by Dr Bristol on "Industrial Health and the General Practitioner" has amplified and correlated the position of the general practitioner and his relationship to the entire problem of Industrial Health in National Defense.

In the Kings County Medical Society there has been organized a Committee on Industrial Health. We have recognized, as Dr Selby has pointed out, that the Medical Service in Industry is predominantly in the hands of the general medical practitioners. As a committee we are familiar with the fact that comparatively few industries have physicians in their employ either full time or part time. It therefore becomes essential for organized medicine to assume the responsibility of forcefully bringing home to the general practitioner the important part that is his in this entire program of Industrial Health. We have received the fullest cooperation from the Council on Industrial Health of the American Medical Association, especially through their printed bulletins.

I agree with Dr Bristol that it would be advisable for the State Society to create a standing committee on Industrial Health. Similar committees in the component county medical societies should be organized. Although the basic problems and principles are the same in all county societies, special problems may arise in certain communities, as occur with a sudden shift of a large population to a given area.

Such problems require the complete cooperation of the committee on industrial health, the general practitioner, and the public health officers. Likewise, in certain localities, the use of special chemicals or metals may require the education of the practitioners in the given locale in the early recognition of occupational disease. The problems that arise can be promptly and competently met, if proper organization exists and all forces intergrade.

The conception of medical service in industry, as outlined by Dr Selby, needs little comment. Prevention of disease or injury has always been recognized as the first step in any program.

Progress in the control of occupational disease

continues The physician in industry makes his contribution in the field of Preventive Medicine The value of the service by the physicians in industry should not be estimated by the number of patients referred to the family physician for treatment upon discovery of such diseases as tuberculosis, syphilis, etc., as a result of an industrial physical examination but rather from the larger, namely, the public health, point of view

The physician in industry is adequately discharging his responsibilities to his patients and to the medical profession. Dr Bristol has ably discussed the position of the general practitioner in his relationship to this entire question of Industrial Health in National Defense

There can be no difference of opinion as to the importance of an adequate health examination for all individuals If periodic health examinations could be made obligatory among all individuals we would have an index of the health of the Nation which would be of immense value The position of the family physician in relation to the

periodic health examination has been ably reviewed by Dr Woody It does seem essential from the industrial point of view, however, that a complete physical examination should include an x-ray examination of the chest, an examination of the eyes, ears, etc., in order that the health of the worker, as well as the interest of the public, is adequately protected This physical examination by teams of specialists under the supervision of the county medical societies may be desirable The result of such examinations and recommendations for treatment can be forwarded to the family physician

The term "vocational examination" rather than the term pre-employment or employment examination would seem more fitting The term "vocational examination" more accurately describes the purpose of the health examination The education of the physician and more especially the education of the public is most essential in this program of Industrial Health and Vocational Health Examinations

AN EXAMINATION COMING UP? PREPARE AT THE RACES, CORNER MOVIE

The "midnight oil" burns no more, for cramming avaleth naught according to high-school teachers who recently took an examination in New York City They called the questions "silly" and "assumed" but the Board of Examiners had no apologies to make Here are some samples

- 1—The planet that in November, 1940, crossed the face of the sun thirty seconds later than the astronomers had predicted was (a) Venus, (b) Mars, (c) the moon, (d) Saturn, (e) Mercury
- 2—Much publicity has been given to experiments by scientists who claim to predetermine the sex of cats, dogs, etc., by the use of (a) adrenalin, (b) sulfanilamide, (c) hormones, (d) vinegar, (e) baking soda
- 3—The race horse which became the world's greatest money winner in 1940 was (a) Man o' War, (b) Seabiscuit, (c) Level Best, (d) Kayak II, (e) Eight-thirty
- 4—In February, 1940, Joe Louis fought with Arturo Godoy The fight lasted (a) two,

(b) seven, (c) eleven, (d) fifteen, (e) twenty rounds

- 5—The star of the French film "The Baker's Wife" was (a) Jean Gabin, (b) Maurice Chevalier, (c) Will Fyffe, (d) Conrad Veidt, (e) Ramu
- 6—A recent collection of verse by Ogden Nash is entitled (a) "No Stone Unturned," (b) "Behind the Lines," (c) "All Gaul Is Divided," (d) "The Face Is Familiar," (e) "Spring Will Not Fail"
- 7—"Foreign Correspondent" was directed by (a) Frank Capra, (b) Cecil B DeMille, (c) John Ford, (d) Alexander Korda, (e) Alfred Hitchcock
- 8—The polo player who retired in 1940, after being the top player for ten years, was (a) Stewart Iglehart, (b) Cecil Smith, (c) Robert L. Gerry, Jr., (d) Thomas Hitchcock, Jr., (e) Alan L. Corey, Jr
- 9—The best way to stop a nosebleed is to use (a) baking soda, (b) salt pork (c) cotton, (d) beef liver, (e) silk

[Answers on page 2051]

ARE YOU WEARING A P C G N Y BUTTON?

Every contributor to the Physicians' Committee of Greater New York—the Medical Aid Department of the British War Relief Society—receives a button upon making a donation It is very attractive with the emblem of Aesculapius shown in white on a green Geneva Cross which is encircled in royal blue If you haven't yours, mail in your contribution to Dr Adolph G. DeSanctis, chairman of the Physicians' Committee of Greater New York, The New York Academy of Medicine, 2 East 103rd Street, New York City There is no need to tell you what your help will do

The committee was organized last April by Mrs W. Coda Martin and Dr Alfred Hellman, president of the New York County Medical Society

The other officers are Dr B. Wallace Hamilton, secretary, Dr Kirby Dwight, treasurer, Dr Chas. Gordon Heyd, Manhattan vice-chairman, Dr John E. Jennings, Brooklyn vice-chairman, Dr Nathan B. Van Etten, Bronx vice-chairman, Dr H. P. Mencken, Queens County vice-chairman, and Dr Herbert A. Cochrane, Staten Island vice-chairman

CLINICAL STUDIES IN ELECTROCARDIOGRAPHY

IV The Value of the Electrocardiogram in Coronary Thrombosis, with Special Reference to Localization of Infarct

ABRAHAM LIEBERSON, M D , JULIUS CHASNOFF, M D , and A ALLEN GOLDBLOOM, Major, Medical Corps, Army, U S A , New York City

EVER since the studies of Smith,¹ Herrick,² Pardee,³ and others who described the characteristic electrocardiographic changes after acute coronary occlusion, the exact correlation between this condition and its electrocardiographic representation has been of great clinical interest. The importance of the role played by the electrocardiogram in the diagnosis and prognosis of coronary occlusion has been appreciably increased by the work of Parkinson and Bedford⁴ (and independently by Barnes and Whitten⁵) who differentiated, in 1928, the prominent electrocardiographic changes in lead I caused by anterior infarct (T_1 type) from that seen in posterior infarction where similar changes are found in lead III (T_3 type). Wilson and his coworkers⁶ further differentiated the prominent Q and QRS changes in the first lead in anterior infarction (Q_1 type) from the QRS changes in lead III in posterior infarction (Q_3 type). This electrocardiographic localization of the infarct is believed to be not purely of academic but of prognostic importance by many observers. Wood and his coworkers⁷ feel that posterior infarction (right coronary) is more favorable than anterior infarction (left coronary).

In 1932 the accuracy of the electrocardiographic detection and localization of coronary infarction was further increased by the use of chest leads, introduced by Wolferth and Wood⁸ after the experimental work of Wilson.⁹ The 4-lead electrocardiogram was found to be especially revealing when repeated often so that the serial changes could be followed, particularly in lead IV.¹⁰ In 1938 a standardization of the various chest leads in use was effected following our original suggestion,¹¹ so that we are now beginning to exploit fully the electrocardiogram as a help in the diagnosis of coronary occlusion. A similar refinement has occurred in the pathologic study of postmortem material in coronary occlusion. The coronary vessels are now all traced to their minutest branches, and the

scars and aneurysmal bulging of old infarcts are noted as well as the myomalacia of more recent ones. In short, we are beginning to be in a position to determine how accurate the electrocardiogram is in the diagnosis and localization of cardiac infarction by use of serial 4-lead electrocardiograms and refined pathologic technique. We expect to obtain enough material in the next four or five years to report upon it at the end of that time.

There is, however, a definite clinical need at present to pause and review our past findings in the light of our present knowledge of this disease, for only rarely in our private practice are we able to follow a case with numerous 4-lead electrocardiograms and conclude the study with a thorough postmortem examination, especially since the patient often reaches exitus before electrocardiograms can be taken. The most common situation as we find it in practice is still one where we are asked to determine from a single 3- or 4-lead electrocardiogram and the clinical examination of the patient whether coronary occlusion has taken place. We therefore feel it worthwhile to review the 34 patients with coronary thrombosis proved by autopsy at Beth Israel Hospital, New York City, in the past ten years, who had one or more electrocardiograms taken before death. Usually a single 3-lead electrocardiogram was obtained. Aside from some clinical correlation that we shall speak of later, our main interest was to compare the accuracy of clinical as against electrocardiographic diagnosis in coronary occlusion and the accuracy of electrocardiographic localization of the infarct.

The 34 cases were classified clinically as shown in Table 1. The electrocardiographic findings in these cases (see Table 2) fall conveniently into three groups. A—characteristically infarct, either anterior or posterior in type, B—block, and C—nonspecific myocardial damage. The criteria for anterior and posterior infarction are those advocated by Barnes and by Wilson (raised RS-T interval in lead I, inverted T_1 , deep Q_1 with small slurred QRS in lead I in anterior infarction, and raised RS- T_3 , inverted T_3 , and deep Q_3 in posterior infarction). All cases of complete

From the medical service of Dr. I. W. Held and the Pathology Department of Beth Israel Hospital.

Approved for publication by The Surgeon General, U S Army, August 11 1941

TABLE 1—CLINICAL MATERIAL STUDIED

	Men	Per- cent- age	Women	Per- cent- age	Total
Number of cases	24	71	10	29	34
Youngest—oldest	35–72		46–76		
Average age at death	57		57		57
Coronary infarct with angina	9	37	0	0	9
Coronary infarct with hypertension	7	29	5	50	12
Coronary infarct with diabetes	5	21	5	50	10

heart block, bundle branch block, or intraventricular block were classified under group *B*. Low voltage or marked slurring of QRS or low-voltage T-waves were classified under group *C*. Tables 2 and 3 show the actual condition found at autopsy corresponding to the various electrocardiographic groupings.

Reference to Table 1 shows that of the 34 patients with fatal coronary thrombosis 10 were women (29 per cent). The average age for the women was the same as for the men—57 years. The coronary thrombosis was associated with diabetes in 5 of the 24 men (21 per cent) and in 5 of the 10 women (50 per cent). The high incidence of complicating diabetes in these women with fatal coronary thrombosis is more than coincidental and appears of definite prognostic import, especially when the incidence of diabetes in these fatal cases (10) is compared with a similar group of nonfatal coronary occlusion cases (3) (see Table 4).

There was a history of previous hypertension in 7 men and 5 women of the 34 autopsied cases. A history of previous angina pectoris was obtained in 9 men but in not a single woman. It is indeed an interesting clinical situation—five women with definite histories of antecedent hypertension dying of coronary occlusion and not a single one with previous angina—demonstrating strikingly the clinical fact that angina is essentially a disease of the male.

We also considered it worthwhile to study the question of glycosuria in these cases of coronary thrombosis, since many observers report the frequent association clinically of glycosuria with acute coronary occlusion in nondiabetics.¹² A review of our 34 cases showed that glycosuria occurred in 9 cases but only in 2 that were not definitely chronic diabetic patients. In 1 nondiabetic case a slight trace of sugar was found in the urine, but the blood sugar was only 100 mg. In the second case a slight trace of sugar was found on only one occasion, but it was negative at all other

TABLE 2—SHOWING ELECTROCARDIOGRAPHIC AND PATHOLOGIC CLASSIFICATION OF CASES

Electrocardiographic	Type— Number of cases	Autopsy		
		Ante- rior	Poste- rior	Anterior and posterior
(A)				
Anterior infarct	8	8		
Posterior infarct	8		7	1
(B)				
Bundle branch (left)	4	1	1	2
Intraventricular block	5	4		1
Complete heart block with ventricular tachycardia	1	1		
Heart block with left bundle branch block	1			1
(C)				
Nonspecific myocardial damage	7	2	1	4
Total	34	16	9	9

times. Our experience, therefore, is that there is no clinical association of glycosuria with acute coronary thrombosis.

Little more than this cursory review of some interesting clinical correlations that we found in our cases is needed when we consider the fine clinical monographs on this subject, such as Levine's¹³ and Levy's.¹⁴ We come then to our main task—the evaluation of the role played by the electrocardiogram in the diagnosis of coronary thrombosis. It is important here to compare the accuracy of the older method of diagnosing coronary occlusion—the clinical—with the newer method alone—the electrocardiographic—and consider, finally, how one method supplements the other. Table 3 is a convenient charting of the clinical diagnosis in each case before the electrocardiogram was taken as compared to the actual autopsy findings. This is contrasted with the electrocardiographic findings per se as compared with autopsy findings. Table 3 shows that of these 34 proved cases of coronary thrombosis 26 were correctly diagnosed on clinical grounds alone while only 16 were diagnosed electrocardiographically as coronary thrombosis. In 12 cases both the electrocardiogram and the clinical diagnosis were correct. In 14 cases the clinical diagnosis was correct while the electrocardiogram was not of specific value. In only 2 cases did the electrocardiogram definitely point to the correct diagnosis of coronary thrombosis in the absence of any clinical evidence, and in 2 more cases the electrocardiogram was mildly suggestive of an acute coronary process in the absence of a positive clinical diagnosis. When clinical impressions were combined with electrocardiographic findings, 31 of the 34 cases were correctly diagnosed, indicating the complementary nature of the clinical and electro-

TABLE 3—SHOWING CORRELATION OF CLINICAL AND ELECTROCARDIOGRAPHIC DIAGNOSES WITH AUTOPSY FINDINGS

No	Clinical Diagnosis Before Electrocardiogram	Correlation with Autopsy	Electrocardiographic Diagnosis	Correlation with Autopsy	Autopsy

30	Hypertensive cardiac in failure	—	Nonspec. myocard. damage	—	Ant. and post.
31	Coronary sclerosis with ac. coronary thrombosis	+	Bundle branch block left	—	Ant. and post.
32	Coronary sclerosis and thrombosis	+	Nonspec. myocard. damage	—	Ant. and post.
33	Nephritis—hypertension with coronary thrombosis	—	Posterior infarct	+	Ant. and post.
34	Coronary sclerosis	—	Bundle branch block left	—	Ant. and post.

cardiographic findings in coronary occlusion

Reviewing the electrocardiographic findings in these cases (Tables 2 and 3), one notes immediately that there was no case of coronary thrombosis in this series in which the electrocardiogram was entirely normal. In more than half of the cases, however, only some nonspecific form of myocardial damage could be diagnosed, and no definite indication of coronary thrombosis was present. Thus, in fully 11 cases left bundle branch block and intraventricular block were present, covering up in all probability the electrocardiographic changes produced by coronary occlusion. In 6 more cases the electrocardiogram showed myocardial damage but not specifically of coronary configuration. We did not come across any case in which the electrocardiogram was typically that of anterior infarction that pathologically showed posterior infarction or vice versa. In our cases whenever the electrocardiogram was characteristically anterior or posterior infarct in type, the autopsy confirmed the localization. This is in agreement with the report of Barnes¹⁵ and the more recent report of Sprague and Orgain¹⁶ and disagrees with Gilchrist and Ritchie¹⁷ and Smith,

Goodrich, and Needles¹⁸ who have found in several cases inconsistencies in the electrocardiographic localization. We believe that although there is little doubt of the localizing powers of the electrocardiogram when it is of the characteristic acute coronary pattern there is unfortunately little justification for the concept that there is any appreciable difference prognostically between anterior and posterior infarct. We have come to this conclusion by comparing the frequency of anterior and posterior infarcts in the 34 fatal cases here reported with 34 nonfatal cases gleaned from the Beth Israel Hospital files of the same 1929-1939 period (see Table 4). This shows that the group that survived the coronary occlusion was similar to the fatal group with respect to age, sex, previous history of hypertension, and angina. Diabetes was much commoner in the fatal group. Electrocardiographically, however, although the incidence of anterior and posterior infarction is about the same for both groups, the fatal cases much more often showed a low voltage (14 fatal to 5 nonfatal cases), bundle branch or intraventricular block (11 fatal to 1 nonfatal case), and also nonspecific myocardial damage

ELECTROCARDIOGRAPHY

TABLE 4.—CLINICAL AND ELECTROCARDIOGRAPHIC COMPARISON OF 34 AUTOPSED CASES WITH 34 CORONARY OCCLUSION CASES WHICH SURVIVED

Number of cases	Died	Survived
Men	34	34
Women	24	26
Average age	10	9
With angina	57	57
Hypertension	8	9
Diabetes	13	10
Low voltage (less than 5 mm.)	10	3
Rel low voltage (less than 7 mm.)	14	5
Anterior (T ₁) type electrocardiogram	6	4
Posterior (T ₂) type electrocardiogram	8	16
Combined T ₁ and T ₂ type electrocardiogram	8	12
Block type of electrocardiogram	11	1
Nonspecific myocardial damage type of electrocardiogram	7	1
Insufficient electrocardiographic changes to diagnose myocardial damage	0	3
		1

(7 fatal to 3 nonfatal cases) This is probably explained by the fact that the electrocardiogram is more characteristic with a single fresh infarct and, prognostically, this is more favorable than the noncharacteristic electrocardiogram seen in chronic cases with multiple infarcts. This similarity in the prognostic significance of anterior and posterior infarction was also found in the recent report of Smith, Goodrich, and Needles.¹³ The distinct advantage that the electrocardiogram has over clinical examination in coronary thrombosis—the localization to the front or the back of the heart—to the left or the right coronary is thus seen to be largely of academic, rather than practical, prognostic importance.

Table 3 clearly demonstrates the most important single fact to be gleaned from this study—that more than half of the cases of coronary thrombosis in this series failed to show definite electrocardiographic signs of this condition. If the electrocardiogram alone were considered, the diagnosis would have been missed more than half of the time. On combined clinical and electrocardiographic evidence, on the other hand, the diagnosis was made in 91 per cent of the cases. This sounds a clear-cut warning against overemphasis on the electrocardiogram to the exclusion of clinical consideration in the diagnosis and prognosis of coronary thrombosis.

It is important at this point to make some accounting for the low percentage of correct electrocardiographic diagnoses in this series.

The most important difficulty is the frequent accompaniment of intraventricular, arrhythmia, or bundle branch block (32 per cent of our cases), which dominates the electrocardiographic picture and suppresses the evidence of coronary thrombosis. Another difficulty is the fact that the classic electrocardiographic tracing of coronary thrombosis is present mainly in the first or second infarction when the heart muscle, aside from the fresh infarct, is relatively normal. After repeated infarctions an indefinite electrocardiographic expression occurs. The same considerations hold in large infarcts involving both the anterior and posterior walls of the ventricle. The electrocardiographic changes produced by the anterior portion of the infarct are largely neutralized by the reciprocal changes produced by the posterior portion of the infarct, resulting in a noncharacteristic picture. With the larger infarcts, too, the septum is often involved, and the resulting intraventricular or bundle branch block covers up the electrocardiographic characteristics of coronary throm-

bosis. It is thus seen (Table 2) that of the 25 cases that had single infarcts at postmortem 15 showed the electrocardiographic diagnostics of coronary occlusion, while of the 9 cases with combined anterior and posterior infarcts only 1 gave a typical electrocardiogram [see Case 32, Table 3, which showed posterior (T₂) type electrocardiogram]. In contrast to this, Table 3 shows that in these 9 cases with multiple infarcts the correct diagnosis was made clinically in 6. There appears to be little doubt that a single fresh primary infarct is likely to give the characteristic electrocardiographic picture and also the characteristic clinical picture. With secondary infarcts in chronic coronary sufferers and in long-standing cases, fresh infarction is most often overlooked if only electrocardiographic evidence is sought but will be correctly diagnosed in the majority of cases by clinical evidence alone if the possibility of a new infarction in old coronary sufferers is constantly kept in mind. Translated into practical language this means that if a patient with an old infarction or with coronary sclerosis appears clinically to have had a fresh coronary occlusion and the electrocardiogram shows nothing characteristic of an acute coronary closure the greatest likelihood is that a coronary thrombosis has occurred, and the patient should be treated accordingly.

It may be said in criticism of the above statement that if chest leads as well as the conventional leads were taken the percentage of correct electrocardiographic diagnoses increased¹⁴ and that, occasionally, serial studies indicate the possible presence of an acute process in the heart which may not be apparent in a single electrocardiogram. It is the uncom-

TABLE 3—SHOWING CORRELATION OF CLINICAL AND ELECTROCARDIOGRAPHIC DIAGNOSES WITH AUTOPSY FINDINGS

No	Clinical Diagnosis Before Electrocardiogram	Correlation with Autopsy	Electrocardiographic Diagnosis	Correlation with Autopsy	Autopsy

34	Coronary sclerosis	—	Bundle branch block, left	—	Ant. and post.

cardiographic findings in coronary occlusion.

Reviewing the electrocardiographic findings in these cases (Tables 2 and 3), one notes immediately that there was no case of coronary thrombosis in this series in which the electrocardiogram was entirely normal. In more than half of the cases, however, only some nonspecific form of myocardial damage could be diagnosed, and no definite indication of coronary thrombosis was present. Thus, in fully 11 cases left bundle branch block and intraventricular block were present, covering up in all probability the electrocardiographic changes produced by coronary occlusion. In 6 more cases the electrocardiogram showed myocardial damage but not specifically of coronary configuration. We did not come across any case in which the electrocardiogram was typically that of anterior infarction that pathologically showed posterior infarction or vice versa. In our cases whenever the electrocardiogram was characteristically anterior or posterior infarct in type, the autopsy confirmed the localization. This is in agreement with the report of Barnes¹⁵ and the more recent report of Sprague and Organ¹⁶ and disagrees with Gilchrist and Ritchie¹⁷ and Smith,

Goodrich, and Needles¹⁸ who have found in several cases inconsistencies in the electrocardiographic localization. We believe that although there is little doubt of the localizing powers of the electrocardiogram when it is of the characteristic acute coronary pattern there is unfortunately little justification for the concept that there is any appreciable difference prognostically between anterior and posterior infarct. We have come to this conclusion by comparing the frequency of anterior and posterior infarcts in the 34 fatal cases here reported with 34 nonfatal cases gleaned from the Beth Israel Hospital files of the same 1929-1939 period (see Table 4). This shows that the group that survived the coronary occlusion was similar to the fatal group with respect to age, sex, previous history of hypertension, and angina. Diabetes was much commoner in the fatal group. Electrocardiographically, however, although the incidence of anterior and posterior infarction is about the same for both groups, the fatal cases much more often showed a low voltage (14 fatal to 5 nonfatal cases), bundle branch or intraventricular block (11 fatal to 1 nonfatal case), and also nonspecific myocardial damage

THE INCIDENCE OF HEART DISEASE IN THE UNIVERSITY STUDENT AGE GROUP

MURIEL CUYKENDALL, M D , Ithaca, New York

THE university student age group is unique in the study of heart disease. At this age, the rheumatic state has already produced recognizable lesions in practically all susceptible hearts, the severe congenital heart diseases have either terminated or the patients are not ambulatory. On the other hand, the types of heart disease resulting from syphilitic and degenerative changes have not yet developed.

No survey to date has published results on the incidence of heart disease in this age group. Figures are available on many surveys conducted in grade and high-school groups, and the incidence in the adult population has been estimated, but the university age group has been surprisingly neglected.

The cardiac program of the Student Health Service at Cornell University was instituted seven years ago and was extended three years ago to include the men students. The present survey is limited, however, to the 6,489 men and women students in residence during the academic year 1938 to 1939. All the cardiac examinations were made by one physician, myself, and thus the diagnoses and criteria for classification are self-consistent.

Sources of Material

Cardiac examinations were given to the following: (1) Students with a cardiac abnormality discovered on the entering physical examination. This routine entrance examination, about forty-five minutes in duration, with the student stripped, was conducted by some one of the eleven staff members of the Department of Hygiene and Preventive Medicine. As a part of the examination, the heart was tested for its size, for the character and position of the apex beat, and for the presence of a thrill and murmur. The blood pressure was recorded. The rhythm of the pulse was noted, and a cardiac function test was made by having the student perform a standard exercise. Upon the slightest suspicion of heart abnormality the student was referred to me for further cardiac examination. (2) A chest roentgenogram was available at the option of each student for a nominal fee, and in case the cardiac shadow

in this picture was abnormal, the student was given the cardiac examination. (3) Students who consulted the Student Health Service complaining of signs or symptoms referable to the heart were examined for cardiac diagnosis.

The Cardiac Examination

The cardiac examination consisted of palpation, percussion, auscultation, and fluoroscopic examination. A chest roentgenogram in the posterior position was usually made, and supplemental roentgenograms were occasionally made with the student in several oblique positions. An electrocardiogram was usually made. Other laboratory procedures—urinalysis, renal function test, blood counts, sedimentation rate, and basal metabolism—were made when deemed necessary or helpful.

Diagnostic Criteria

Much of the variation in the reported incidence of heart disease is due to a lack of uniform application of a definition of heart disease. Some surveys define organic heart disease as being synonymous with anatomic heart disease. Other surveys include one or more of the subheadings of etiologic or physiologic diagnosis.¹ In particular, incidence variations occur with the inclusion or exclusion of hypertension, psychoneurosis, thyroid diseases, extrasystoles or tachycardia. Other confusions arise from difficulties in the differential diagnosis of borderline organic and functional systolic murmurs.

In this survey the incidence of heart disease is based on the anatomic diagnosis only. The definitions of types of organic heart disease are essentially those established by the American Heart Association. Clarification of certain of the diagnoses was made by rating the intensity of the murmur. Thus, a diagnosis of mitral insufficiency was not made when the intensity of the murmur was less than Grade 2², and a functional murmur was usually less than Grade 2 intensity. The changes in cardiac contour or dynamics characteristic of an organic lesion were always sought by fluoroscopic examination. A diagnosis of lesion was not made unless these accompanying characteristics were observed.

Abnormal processes occurring in the body

¹Assistant professor of hygiene and attending physician, Cornell University.

mon case, however, that shows characteristic signs of acute coronary occlusion in lead IV and no signs of this in the conventional leads, the average of reports indicating that this situation occurs in only 3 or 4 per cent of the cases. The second situation, where serial changes point to a coronary thrombosis not suspected by single electrocardiogram, is also rare, occurring in only 2 or 3 per cent of the cases. It may be also said in criticism of our published results that many of the electrocardiograms were agonal—terminal—and, thus, are less likely to be diagnostic. A careful review of our cases showed, however, that of the 9 cases in which the electrocardiogram was taken one day or less before death 3 showed electrocardiograms characteristic of coronary occlusion while 6 showed block or nonspecific myocardial damage—about the same average of electrocardiographic diagnostic accuracy in the agonal cases as in those where the electrocardiograms were taken days or weeks before death. Finally, it must not be forgotten that lead IV can be of no added assistance with the two main problems in electrocardiographic diagnosis of coronary thrombosis—the presence of block and nonspecific changes. Although our figures for the frequency of incidence of characteristic electrocardiographic changes in acute coronary thrombosis appear lower than those usually reported, it is not due to the lack of lead IV but to the fact that the cases represent not only primary infarction but secondary and multiple infarctions in old coronary sufferers.

Conclusions and Summary

Review of 34 patients who showed myocardial infarction at autopsy (24 men and 10 women) and who had at least one electrocardiogram taken before death emphasizes several interesting clinical correlations. Hypertension and diabetes were commoner in the women than in the men, while a history of angina was obtained in 9 men and in not a single woman. Glycosuria is only a rare accompaniment of acute coronary occlusion.

The autopsy material included 16 cases of anterior infarcts (left coronary), 9 cases of posterior infarcts (right coronary), and 9 cases of combined anterior and posterior infarcts.

Eight cases of the anterior infarcts, 7 cases of the posterior infarcts, and only 1 case of the combined infarcts were detected electrocardiographically. Thus, only 16 of the 34 cases (47 per cent) were diagnosed by the electrocardiogram alone. The other 18 cases showed left bundle branch block or intraventricular block (11 cases) and nonspecific myocardial damage.

In contrast, the *clinical diagnosis* before the electrocardiogram was taken was correct in 26 of the 34 cases (76 per cent). Using both the clinical and electrocardiographic evidence, the correct diagnosis of coronary infarct was made in 31 of the 34 cases (91 per cent). This emphasizes the prime importance of the history and clinical examination in the diagnosis of this condition, particularly in patients who are sufferers of old coronary thrombosis or sclerosis and who are not likely to have a characteristic electrocardiogram with the repeated infarctions.

The authors are deeply indebted to Dr. Isidore W. Held for his invaluable aid in the clinical study of these patients and to Dr. Alfred Plaut for the pathologic study.

ASSOCIATION OF MILITARY SURGEONS

The Association of Military Surgeons of the United States will meet at the Hotel Brown, Louisville, Kentucky, from October 29 to November 1. All members of the medical

profession are cordially invited to attend. The session will conclude with a mass review of military medicine and inspection of Fort Knox.

TABLE 1—CARDIAC DIAGNOSES AMONG STUDENTS, 1939 to 1940

* Aortic insufficiency

† Mitral insufficiency

0.5 per cent in grade-school to 0.9 per cent in high-school children. The incidence in men of military age is 3.0 per cent.¹⁰ In the present university age group, most of whom are between the ages of 17 and 22 years, the incidence is 1.2 per cent. This agrees well with the scattered figures of other surveys.

Sex—A greater incidence of rheumatic heart disease obtains in women than in men. The ratio as reported in other surveys¹¹ has never been more than 4:3. The ratio of 3.2:1 in this survey is therefore striking. Arguments to rationalize the high rheumatic sex ratio in terms of the specialized university group are not satisfying. The increase in the rheumatic state which occurs in girls during adolescence is not sufficient to account for the high ratio.

There are 3.3 times as many men as women students in residence at Cornell University. Men acquire rheumatic heart disease less frequently than women. Thus, the incidence of heart disease in this particular group is lessened because of its sex distribution.

Economic Environment—The incidence of rheumatic heart disease is relatively high in people in a low economic bracket. Raugh¹² classified the incidence of acquired heart disease in school children according to the economic status of the parents. He found the incidence of heart disease to range from 0.32 per cent in the children in the lowest quartile to 0.063 per cent in the children in the highest quartile income bracket.

Wide variation exists in the economic background of the students attending Cornell University. The average level is undoubtedly higher than that of the population as a whole.

Climate—Rheumatic heart disease is more common among people living in a cold climate than among those living in a warm climate. The climate variation was measured by Paul¹³ who made a survey of two groups of North American Indian children, one group living in Wyoming and the other in Arizona.

We assume that Indian hearts are similar to hearts of the white race. In the two Indian groups the factors which affect the rheumatic state were present to a remarkably similar degree except for the climate which in Wyoming was the colder. The children who lived in Wyoming had ten times as much rheumatic heart disease as did those who lived in Arizona.

Race—Rheumatic heart disease occurs less frequently in the negro than in the white race.¹⁴ Less than 25 of the 6,489 students were of the negro race and none of these had heart disease. The number of negro students in this survey is too small to be of statistical value. No effort was made to estimate the incidence in other races.

Comment

The findings of this survey suggest comparison with surveys on other groups of the same age, particularly with students in residence at other universities, and with corresponding ages in other groups in the northern part of the United States. No reports on such surveys are available. However, one may generalize on the expected incidence of heart disease in such groups relative to the incidence at Cornell University.

Of the five known factors which influence the incidence of rheumatic heart disease, possibly two are common to the students of most universities, i.e., the age group and the economic background. The factors which cause the incidence to vary in another university are its location, the proportion of men to women students, and the race distribution. Since these factors cause appreciable variation, a wide range in incidence in university student groups may be expected.

Considering the average economic status, the proportion of men to women, and the proportion of the Negroes to the whites, we conclude further that the incidence of heart disease in the same age group of the general population in the northern part of the United

in regions other than the heart may give rise to signs and symptoms which are referred to the heart. These processes are not considered to be heart disease in this survey. They are noted here for reference purposes.

Hypertension—Hypertension is present when the student's systolic blood pressure is above 140 or the diastolic pressure is above 90 mm Hg. Effort was made to put the student at ease during the examination, and the lowest blood pressure reading of repeated visits was used. Sampson in his study of 16- to 18-year-olds found 10 per cent with hypertension, 64 per cent of whom were boys.² Among the university students of the present study, hypertension was present in only 4.5 per cent of the men and 0.45 per cent of the women students. Comparison of the results of these two surveys proves the need for a standard procedure and technic in making blood pressure readings.

Psychoneurosis—A psychoneurotic basis for symptoms of heart disease was found in 0.2 per cent of the university students, no sex difference was present. The complaints made by the students to the Health Service Office were precordial pain, palpitation, dizziness, fainting, tachycardia, and extrasystoles. Precordial pain occurred frequently in students who feared disease, a fear often caused by a recent cardiac death in the family.

Thyroid Disease—Mild but insignificant changes in the heart due to hyperthyroid or hypothyroid conditions were observed in several students.

Extrasystoles—Premature beats are of common occurrence. They have no effect on the student other than to arouse slight apprehension concerning the heart.

Possible Heart Disease—The diagnosis of possible heart disease was not used in this survey. A definite diagnosis either of heart disease or of no heart disease was made in every case. Borderline cases and suspected cases with evidence inadequate for classification as heart disease were considered to have no heart disease. Such arbitrary diagnosis of heart disease, although not permissible in medical practice, was necessary in a statistical survey. The opinion of the physician was accepted as statistical fact.

Potential Rheumatic Heart Disease—Two surveys were recently published dealing with cases of potential rheumatic heart disease on which observations had been taken during a ten-year period. One of these surveys reported on patients whose onset of potential rheumatic heart disease occurred at about 8 years of age.⁴ Of this group 25 per cent developed a permanent valvular deformity by the age of 18 years. The other survey reported on patients whose age of onset was approximately 14 years of age.⁵ Less than 5 per cent of this group had developed such a deformity at the age of 24 years. Both surveys noted that

the transition to active involvement occurred predominantly during the years closely following the onset of the potential disease. A comparison of these surveys reveals a progressive decrease with age in resultant valvular deformity following the rheumatic state.

The final ages of the groups observed in the two surveys mentioned in the previous paragraph agree well with the age group of university students. Thus, it is logical to assume that the probability of a potential rheumatic heart disease becoming a manifest lesion during the university age or after is very small. Therefore, to include potential rheumatic heart disease as an organic type of heart disease at the university age is to swell unduly the total organic heart disease incidence.

Functional Systolic Murmur—The functional systolic murmur merits special attention because of its close similarity to slight mitral involvement. The prevalence of confusion in these two diagnoses is evident from the fact that the mortality for life insurance entrants with a functional systolic murmur is higher than the mortality for standard lives.⁶

This pseudo disease, most difficult to diagnose, is common and was found in 3.1 per cent of the men and 9.3 per cent of the women students.

Results

The diagnosis of organic heart disease in this survey was limited to the anatomic diagnosis of changes in heart structure. This diagnosis was made in 1.5 per cent of the Cornell students: 1.1 per cent of the men and 3.0 per cent of the women. The distribution among the types of disease is indicated in Table 1. The rheumatic type comprised 82 per cent of the organic heart disease and was present in 1.2 per cent of the students. The mitral valve was involved in 90 per cent of the rheumatic hearts. Rheumatic heart disease was present in 2.6 per cent of the women and 0.8 per cent of the men, a ratio of 3.2 to 1.

Discussion

The incidence of rheumatic heart disease, the most common type of heart disease among the students, is affected by age, sex, economic environment, prevalence of the rheumatic state in the family or environment, and race. A qualitative analysis of these factors in relation to this university group is in order.

Age—The incidence of rheumatic heart disease increases with age. In school children in New York State this incidence is 0.5 per cent,⁷ and in Boston school children, 0.52%. Cahan⁸ found the incidence to increase from

THE MEDICAL DIAGNOSIS OF MENTAL DEFECT

EDWARD J. HUMPHREYS, M D , Thiclls, New York

THE diagnosis of mental defect may be made on the basis of one or a combination of three factors of identification—namely, the existence and nature of the retardation in intellectual growth, the description of the syndrome presented, and the analysis of the causal or etiologic agents responsible for the production of organismic defect. In the early history of the diagnosis of mental defect, identification of defect was made by the physician. During the more recent periods of diagnosis, the physician's diagnosis has been supplemented to increasing degree by contributions from the educator and the psychologist. These contributions are especially valuable in the study of high-grade and borderline types of defectives in relation to the problems of commitment, re-education, and general socialization. Among the contributions of the psychologist the intelligence test results have received special emphasis, but there is growing unanimity of opinion that the diagnosis of mental defect is to be determined by more than an I Q rating alone. This "more than an I Q" is included by diagnosticians under the term "composite classification," which considers the physical and behavioral elements of the patient's experience, as well as the summarized results of the measurements of partial factors of intelligence. In order to make the "composite classification" clinically significant, it is still the physician who is called to make the general diagnosis of mental defect, upon the basis mentioned above, and he can do so with much more detailed assistance than was available to him during the earlier days of diagnosis.

The consideration of the composite or general classification requires the review of biologic and sociologic factors involved in any given case. Many of us believe that the condition of so-called "true mental defect" arises fundamentally from distortion in the vast understructure of organic and psychobiologic organization of the individual regardless of either circumscribed or extensive effects of the environmental forces. The question may be asked "If it were possible to remove the es-

entially subnormal germ plasm from the general population, how much mental defect would remain?" Many would reply that with the removal of the hereditary taints, a large percentage of the so-called "true mental defect" would disappear. This would no doubt also obtain, to an unknown extent, for other conditions of arrest in mental development—as, for example, certain cases of the "temperamental deficiencies" mentioned by Burt and others. Instances of mental defect not included under the hereditary types and in which organic factors are basic would represent individuals who have become defective because of agents that have destroyed or damaged living tissue (the so-called secondary types). Still other types of defect are represented by those who suffer from disabilities that may or may not be due to definite alterations in physiologic activities. Emphasis upon the basic importance of the organic groundsetting of mental defect does not mean for one moment that environmental forces may not strongly contribute to the intensifying of defects in the growth of the organism. Furthermore, in reference to certain persons of borderline intelligence, environmental adversities may throw the person under the technical classification of mental defect. This question still remains, however "Why is it that the person originally was to be found in the 'borderline' or 'dull normal' state of intelligence?" In short, we might conceive of the diagnostic problems of mental defect in a somewhat allegoric manner by saying that mental defect represents a vast storm of social problems whirling upon a deep ocean of organic crosscurrents.

The physician can readily identify certain conditions associated with mental defect such as those of mongolism, cretinism, or phenylpyruvic oligophrenia. For this purpose he has at his disposal the beginning of a helpful classification system—namely, that as found in the *Standard Classified Nomenclature of Disease*. This classification has gone a long way in organizing a more adequate system for the medical identification of mental defectives. It needs further revision, however, as both descriptive and etiologic factors are used somewhat interchangeably. For example, the diagnosis of "000-071 mongolism" is purely descriptive in nature, the etiologic diagnosis

Read at the Northeastern Section Meeting of the American Association on Mental Deficiency held at Mansfield State Training School, Mansfield Depot, Connecticut September 28, 1940

Director of research State of New York Department of Mental Hygiene, Letchworth Village

States will be greater than that of the university students

Summary

In the university student age group the rheumatic state has already produced anatomic change in practically all hearts susceptible to this change but the syphilitic and degenerative heart diseases of middle life have not yet occurred. A survey of the incidence of heart disease was conducted among the 6,489 students in attendance at Cornell University during the academic year 1938 to 1939.

In previous surveys wide variations in the incidence of heart disease result from lack of uniformity in the compilation of material. Some surveys include one or more of the various subheadings of etiologic or physiologic diagnosis. Further variation in the reported incidence is due to confusion in the differential diagnosis of borderline organic and functional systolic murmur. In the present survey the anatomic diagnosis is considered to be the only diagnosis of organic disease. However, certain of the etiologic and physiologic diagnoses with their incidence among Cornell University students are briefly noted so as to make possible a comparison with those surveys which include these additional conditions.

Organic heart disease was diagnosed in 15 per cent of the Cornell students, i.e., 10 per cent of the men and 30 per cent of the women. The rheumatic type of heart disease comprised 82 per cent of the organic heart disease in this group and was present

in 12 per cent of the students. The mitral valve was involved in 90 per cent of the rheumatic hearts. Rheumatic heart disease was present in 26 per cent of the women and 0.8 per cent of the men students, a sex incidence ratio of 3:1.

Rheumatic heart disease is the most common type of heart disease present among the Cornell University students. Factors that are known to influence rheumatic heart disease—namely, age, sex, economic environment, prevalence of the rheumatic state in the community, and race—are found in general to exert the expected influence. An exception, however, is the influence of sex: the ratio of three times as much rheumatic heart disease among the women students as among the men is much greater than in any previously reported survey.

HELPMEET

"I'm sorry, but the doctor's out,
From what you've told me, there's no doubt
Your boy has measles—you must keep
Him in the dark, and let him sleep
Where it is warm—perhaps a spoon
Of oil—the doctor will come soon."
Now was she right? Would he take pride
In such a helpful little bride?
She welcomed him with beaming face,
And cried, "Sweetheart, another case
Were my suggestions all correct?
Has Johnny got what I suspect?"
The doctor's face was long and sad
"Your diagnosis was not bad,
The treatment's recommended, too—
But what is left for me to do?"

T.B. PATIENTS UNDER POLICE GUARD

Under police guard, 26 men and 10 women are being treated for tuberculosis in a wing of the Philadelphia Hospital for Contagious Diseases. There is a policeman standing at the door day and night to see that they do not run away from the city's beneficence, reported *The NT 1 Bulletin*, March, 1941.

These patients are being subjected to compulsory hospitalization under a 30-year-old state law, which for the first time is being invoked in the city's war on tuberculosis.

They were "sentenced" to treatment at the hospital by Judge Charles L. Brown of the Municipal Court. The complainant was the division of tuberculosis of the city department of health.

In each case an agent of the division testified that the defendant repeatedly disobeyed orders to place himself under medical supervision and observe certain hygienic safeguards.

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

The patient was a 53-year-old colored man, admitted on May 15, 1941, complaining of severe precordial pain, dyspnea, orthopnea, and swelling of the ankles. Until three years ago the patient had apparently been in good health. At that time he noted ankle swelling that prevented him from working. Since then he had had occasional episodes of paroxysmal nocturnal dyspnea and ankle edema. One year ago the patient noted the onset of exertional dyspnea and consulted an L. M. D. (local physician) who told him that he had a weak heart. Three weeks prior to admission while climbing the fifth of five flights of stairs, he experienced a sudden severe precordial pain described as "a heavy pressure over the breast bone," the pain lasting for twenty-four hours until relieved by a hypodermic injection. Vomiting occurred shortly after the onset of pain. With the disappearance of the pain he became dyspneic and slightly orthopneic and felt weak. During this three-week interval the patient was apparently digitalized, was given intravenous injections for instituting diuresis, but was not given complete bed rest. Three days prior to admission the patient had a return of the substernal pressure, which continued until the time of admission. The past history revealed that the patient had drunk 1 pint of whiskey per day for the past ten years until three months ago.

The patient was a middle-aged, well-nourished, well-developed colored man, dyspneic, and slightly orthopneic and appeared moderately acutely ill. The temperature on admission was 99.4 F, pulse, 120, respirations, 30, and blood pressure, 130/110. An examination of the head and scalp was negative. The pupils were equal and reacted to light and accommodation, the extraocular movements were normal. There was a small perforation of the nasal septum. The tongue was coated and had smooth edges, and the oropharyngeal mucous membranes were normal. There was no distention or pulsation of the neck vessels. The trachea was in the midline, no tug, the thyroid was not enlarged. The lungs were moderately dull at both bases

with moist rales and diminished breath sounds. The heart was enlarged to the left. The point of maximal impulse was in the sixth interspace in the anterior axillary line. The sounds were weak and rapid, with occasional extrasystoles. The second pulmonic sound was equal to the second aortic. The abdomen was slightly distended and nontender, and the liver edge was soft and three finger breadths below the costal margin. There were no other organs or masses palpable and no ascites. The genitalia were normal male. The reflexes were physiologic, the extremities showed 4 plus ankle edema to 1 plus at the knees.

The blood pressure on admission was 146/110, it gradually fell to 104/84 during the third week and continued at about this level until the time of death. The patient's temperature remained about 101 F during the first week, at the end of which time the erythrocyte sedimentation rate was 52 mm per hour, the blood nonprotein nitrogen was 34, and the blood sugar was 78. The urine showed a concentration to specific gravity of 1.024 with 2 plus albumin, which cleared in four days, with an occasional granular cast, red blood cell and 5 to 7 white blood cells. During the second week the patient's temperature was never above 100.2 F. For the next seven weeks the patient ran a daily spiking temperature ranging between 99.6 and 103 F, rising rapidly at the time of death—the tenth week. The pulse corresponded to the fluctuation in temperature ranging between 70 and 120 per minute. The physical findings were essentially as on admission. It was noted that there was gallop rhythm, poor and feeble heart sounds with a systolic at the apex, and enlargement at the apex moderately to the left. The congestive signs disappeared by the eighth week when the liver was no longer palpable and there was no peripheral edema. Repeated blood counts showed the white cells never to be above 10,900, the polymorphonuclears were never above 76 per cent. The red cells ranged between 4,260,000 and 5,400,000. On June 30 the patient was put on a course of sulfapyri-

being unknown at the present. In another instance, the diagnosis "000-077 with developmental cranial anomalies" indicates only that the mental deficiency may be found to be concomitant with hydrocephalus but not necessarily that the deficiency may be directly due to the hydrocephalus. In still another instance, the diagnosis of "000-077 with endocrine disorder" means that the mental deficiency may be found concomitantly with the endocrine disorder but does not indicate whether the mental deficiency may be directly due to the endocrinopathy or whether the mental defect may represent an expression of a more generalized deficiency of which both the mental and endocrine defects are part-manifestations. Despite the fact that this classification system needs further differentiation, physicians in state or private medical practice are urged to employ this system, at least experimentally, so that out of increasing diagnostic experience in the field of mental deficiency a more adequately descriptive and a more analytic-etologic system may emerge.

The medical diagnosis of mental defect also includes the analysis of so-called "social deficiencies." The physician has a right to include such considerations in his final diagnosis of mental defect primarily through psychiatry, which is an extension of medicine into the field of social science. The word "mental" throughout centuries and throughout the works of present-day investigators into the phenomena of mind has connoted not only elementary physiologic expressions of action

but also those of thinking, will, feeling, emotion, temperament, and character. It is becoming increasingly clear that individuals may exhibit arrests not only in the development of intellectual processes but also in the growth of other integrations of mind. Social deficiencies may thus arise from defects in the ability not only to conceptualize in the terms of name and form but also to evaluate in the terms of social relationships. Ability to do the latter is constantly influenced not only by cognitive forces but by all of the integrations of mental functioning, including the conative and emotional.

It may thus be seen that the medical diagnosis of mental defect depends upon factors both within and adjacent to the field of medicine, that the medical interpretation of mental defect is determined by the clinical training and experience of the physician, and that a physician in diagnosing, and even in treating, mental defect needs the assistance of properly qualified professional workers from specialties within medicine itself and from fields such as psychology and education. If the physician is to improve his diagnostic work in mental deficiency, he must establish more adequately his evaluations of arrest in development, whether in reference to physical, conative, emotional, or characterual qualities of mental organization. The medical diagnosis of mental defect, therefore, is not a simple matter but includes a general recognition of basic underlying organic defects upon which innumerable social influences may act to confuse and arrest the efforts of the organism to mature.

SYPHILIS AMONG SELECTEES

The Division of Venereal Diseases of the United States Public Health Service announced on June 12 that unpublished analyses of serologic and clinical examinations of 1,070,000 selectees and volunteers, as of April 15, 1941, indicate a total of about 48,500 cases of syphilis. For white selectees and volunteers for whom reports were submitted the rate was 18.5 per thousand, for Negroes, 241.2 per thousand. —J.A.M.A.

NO TWO ALIKE

Were all men built to a stock pattern so that they responded to physical agents or bacterial infections in regular fashion according to their peculiar constitution, the practice of medicine would be a simple business. All men, however, are like contrary women of whom the comedian sang "You never see two alike any one time and never see one alike twice."

—Quincy Med Bulletin

PREVENTION OF MENTAL ILLNESS

Many personality difficulties begin as rather simple reactions to ordinary life situations that should be recognized by any physician. If these were recognized they could be corrected in a great number of instances, provided the physician and surgeon treated the patient as a total personality rather than as the mere host to innumerable organs and functions. The real pre-

vention of mental ill health lies in the hands of the family physician, internist, and surgeon to whom the patient first goes for help, not in the hands of the psychiatrist specialist.

—Edward G. Billings, M.D., of the Psych. Liaison Dept. of the Univ. of Colorado School of Med., in an address before the Wisconsin State Medical Society

CLINICOPATHOLOGICAL CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

The patient was a 53-year-old colored man, admitted on May 15, 1941, complaining of severe precordial pain, dyspnea, orthopnea, and swelling of the ankles. Until three years ago the patient had apparently been in good health. At that time he noted ankle swelling that prevented him from working. Since then he had had occasional episodes of paroxysmal nocturnal dyspnea and ankle edema. One year ago the patient noted the onset of exertional dyspnea and consulted an L M D (local physician) who told him that he had a weak heart. Three weeks prior to admission while climbing the fifth of five flights of stairs, he experienced a sudden severe precordial pain described as "a heavy pressure over the breast bone," the pain lasting for twenty-four hours until relieved by a hypodermic injection. Vomiting occurred shortly after the onset of pain. With the disappearance of the pain he became dyspneic and slightly orthopneic and felt weak. During this three-week interval the patient was apparently digitalized, was given intravenous injections for instituting diuresis, but was not given complete bed rest. Three days prior to admission the patient had a return of the substernal pressure, which continued until the time of admission. The past history revealed that the patient had drunk 1 pint of whiskey per day for the past ten years until three months ago.

The patient was a middle-aged, well-nourished, well-developed colored man, dyspneic, and slightly orthopneic and appeared moderately acutely ill. The temperature on admission was 99.4 F, pulse, 120, respirations, 30, and blood pressure, 130/110. An examination of the head and scalp was negative. The pupils were equal and reacted to light and accommodation, the extraocular movements were normal. There was a small perforation of the nasal septum. The tongue was coated and had smooth edges, and the oropharyngeal mucous membranes were normal. There was no distention or pulsation of the neck vessels. The trachea was in the midline, no tug, the thyroid was not enlarged. The lungs were moderately dull at both bases

with moist rales and diminished breath sounds. The heart was enlarged to the left. The point of maximal impulse was in the sixth interspace in the anterior axillary line. The sounds were weak and rapid, with occasional extrasystoles. The second pulmonic sound was equal to the second aortic. The abdomen was slightly distended and nontender, and the liver edge was soft and three finger breadths below the costal margin. There were no other organs or masses palpable and no ascites. The genitalia were normal male. The reflexes were physiologic, the extremities showed 4 plus ankle edema to 1 plus at the knees.

The blood pressure on admission was 146/110, it gradually fell to 104/84 during the third week and continued at about this level until the time of death. The patient's temperature remained about 101 F during the first week, at the end of which time the erythrocyte sedimentation rate was 52 mm per hour, the blood nonprotein nitrogen was 34, and the blood sugar was 78. The urine showed a concentration to specific gravity of 1.024 with 2 plus albumin, which cleared in four days, with an occasional granular cast, red blood cell and 5 to 7 white blood cells. During the second week the patient's temperature was never above 100.2 F. For the next seven weeks the patient ran a daily spiking temperature ranging between 99.6 and 103 F, rising rapidly at the time of death—the tenth week. The pulse corresponded to the fluctuation in temperature ranging between 70 and 120 per minute. The physical findings were essentially as on admission. It was noted that there was gallop rhythm, poor and feeble heart sounds with a systolic at the apex, and enlargement at the apex moderately to the left. The congestive signs disappeared by the eighth week when the liver was no longer palpable and there was no peripheral edema. Repeated blood counts showed the white cells never to be above 10,900, the polymorphonuclears were never above 76 per cent. The red cells ranged between 4,260,000 and 5,400,000. On June 30 the patient was put on a course of sulfapyri-

dine with a slight diminution in the febrile state, receiving then a total of 15 Gm Sulfapyridine was again started eight days before death, then being given in $\frac{1}{2}$ -Gm doses. During the last two weeks the patient became progressively weaker and more dyspneic, and episodes of paroxysmal tachycardia were noted. In the last five days the patient's temperature gradually rose to 107 F at the time of death, with a heart rate of 150. During the last week the urine again showed 2 to 3 plus albumin concentrating to specific gravity of 1.025. The blood sulfapyridine levels were 6.7 and 9.4, respectively. The icteric index on July 2 was 9, a blood culture taken on this day was negative. Agglutination tests for the typhoid group were all negative. A roentgenogram of the chest taken on July 17 showed the heart to be markedly enlarged in the transverse and longitudinal diameters, with accentuation of the left ventricular curve due to considerable left ventricular hypertrophy. There was present hypervascularization throughout both lungs. The electrocardiogram on admission showed inverted T₁, T₄ with depressed R-T segment in lead IV, with a sinus tachycardia and left axis deviation. Subsequent serial electrocardiograms showed inverted T of the seagull type in leads I and IV with return to the base line of the S-T segment in lead IV and again became depressed during the fourth week to return to the base line after three more weeks, at which time the T₄ became upright. A left bundle branch block and occasional premature contractions of nodal origin were noted during the seventh week. The patient received, in addition to symptomatic treatment, mercupurin.

Discussion

DR. MAX TRUBEK: It was logical to assume that this patient had a pre-existing hypertension and that the preceding symptoms of congestive failure were on the basis of myocardial insufficiency due to hypertrophy. The left ventricle showed considerable enlargement and, in the absence of valvular disease or of a preceding story to suggest the presence of widespread coronary sclerosis, hypertension was left as the most logical etiologic factor. It is a common finding in the Negro race. The initial episode of the present illness, characterized by prolonged precordial pain with accentuation of the manifestations of cardiac failure, certainly point to coronary insufficiency and, as subsequent events showed, to myocardial

infarction. There was not, however, the expected restitution of cardiac function or a drop in temperature such as would be expected after a usual episode of myocardial infarction. There was a persistence of the tachycardia with apical gallop rhythm, progressive decline in blood pressure and pulse pressure, maintained elevation of the erythrocyte sedimentation rate, and continued elevation of the temperature over a period of five weeks. An attempt was made to correlate these findings by surmising the presence of a large mural thrombus associated with the necrotic myocardium. Previous experience suggested this possibility as a cause particularly for the maintained fever that was otherwise not explainable. There was a terminal abrupt rise in temperature which was considered due to pulmonary hypostasis in a patient already moribund. No examination of the fundi oculi was recorded which might have confirmed our impression of a long standing hypertension, although the elevated diastolic pressure present at first was adequate confirmation. The question of a syphilitic aortitis and stenosis of the coronary ostia was ruled out as a clinical possibility in the differential diagnosis.

DR. CHARLES H. NAMMACK: Historically, clinically, and electrocardiographically this case was one of failure of the cardiovascular dynamics. We have frequently seen cases of perforation of the nasal septum which were not confirmed by positive serology as being syphilitic.

DR. TRUBEK: We have seen several cases on this service in which there have been electrocardiographic changes, indicating coronary occlusion with myocardial infarction, which ran a prolonged febrile state and subsequently at autopsy showed mural thrombus without embolization. In myocardial infarction with healing, the temperature remains persistently high for the first to second week and then gradually returns to normal with a later corresponding decrease in the erythrocyte sedimentation rate. However, I feel that the diagnosis of mural thrombus following extensive myocardial necrosis was the best possible diagnosis in this case, in spite of the fact that the patient continued a daily spiking temperature with little or no response to sulfapyridine.

DR. ARNOLD KOFFLER: It is possible that this patient had an infarction in the posterior wall of the left ventricle with involvement of the septal portion with production of bundle branch block. This patient may have had

multiple small acute occlusions that at autopsy might not have been evident except as demonstrated by the injection method of Blumgart and Schlessinger. The temperature, which was atypical of infarction *per se*, may be explained on the basis of necrosis of the infarct or, failing this, it may have been from some cause that has not yet been demonstrated in this case.

DR. HENRY C. FLEMING One might have suspected the possibility of syphilis as the etiologic factor in this case. There was no evidence for either coronary ostial stenosis or aortic regurgitation. I believe that this was a case of myocardial infarction rather than that of mere occlusion. The fact that the erythrocyte sedimentation rate remained elevated and that the electrocardiogram showed only the changes characteristic of an initial insult to the myocardium led us to believe that there were no subsequent infarctions of the myocardium. The temperature typifying coronary occlusion falls with healing, and this process usually occurs within a few weeks. Patient showed no response to chemotherapy. Because of the septic state in this patient one might think that there was a thrombophlebitis of some part of the body. Thrombophlebitis is sometimes missed at autopsy. The white blood count does not tell us anything about an infectious process, the erythrocyte sedimentation rate does tell us much more.

DR. ARTHUR L. WASHBURN There was no evidence of syphilitic involvement of the cardiovascular system. However, syphilis could be present in spite of a negative blood Wassermann. A large group of syphilis patients in the tertiary state show negative blood Wassermann reactions.

DR. MENNASCHE KALKSTEIN Another possibility to be entertained is a mural thrombus attached to the interventricular septum and extending into the right, as well as the left, ventricle, giving rise to repeated small emboli to the lungs.

DR. TRUBEK Right ventricular thrombus is a rare condition.

DR. WASHBURN Emboli should show in the x-ray.

DR. KALKSTEIN Minute emboli are frequently overlooked.

DR. HARRY A. SOLOMON The outstanding point in this case was the toxic, progressively failing heart. It would have been possible for this patient to have had an aneurysm of the left ventricle or some other intrinsic heart lesion. However, I feel that this patient had a myocardial infarction leading to myocardial

necrosis and cardiac failure. I think, clinically, that there was no other cause for the toxic, remittent state than absorption from a necrotic myocardium. By administering sulfapyridine, we attempted to take the load off the heart by reducing the fever. This case began as one of left failure subsequently going into right failure followed by prolonged fever. This is not the first time that we have seen such cases.

Presentation of Pathology

DR. MAX-WILHELM JOHANNSEN At necropsy the interesting findings were confined to the heart, which weighed 540 Gm. The pericardium was thin and smooth, and its cavity contained about 75 cc of dark fluid. The endocardium of the right auricle and ventricle and that of the left auricle was thin, smooth, and glistening. The myocardium of these chambers was of normal thickness and light brown in color. The tricuspid, pulmonary, mitral, and aortic valves were thin and delicate and appeared functionally competent. On examining the left ventricle it was seen to be greatly hypertrophied and dilated. On the posterior external aspect was a pale yellow area covering nearly the entire inferior half of the ventricular wall. On examining the interior of the left ventricle, a large mural thrombus was found on the posterior wall, bulging into the lumen of the chamber. In places, this thrombus was deep red, in other places, pale. It was fibrinous throughout and could be separated only with difficulty. On section of the myocardium it could be seen that there was extensive infarction and necrosis and fibrosis of the posterior wall of the ventricle, this process extended down to include the apex. The coronary ostia were patent, careful examination of all the coronary arteries revealed no stenosis or occlusion adequate to explain the infarction, but the vessels were of an extremely fine caliber and were barely traceable after the midportion of the heart. The remainder of the organs showed, except for chronic passive congestion, no noteworthy changes.

Clinically, as far as I can see, there was no doubt that the patient had a myocardial infarction. The point of primary interest rests in the cause for the prolonged spiking temperature. You have heard in the description of the necropsy findings that the myocardial infarction was found but that there was no evidence of coronary occlusion. The patient had a poorly developed coronary circulation, the major branches being barely traceable in

the lower half of the heart. When this patient developed myocardial hypertrophy, the coronary circulation became inadequate. The major physical exertion of climbing five flights of stairs could very well have produced acute coronary insufficiency with myocardial ischemia and subsequent necrosis.

As to the second point of interest, the clinicians tried to explain the prolonged temperature on progressive myocardial infarction. True enough, myocardial infarction may give rise to a fever, but this fever rarely lasts more than seven days. Progressive infarction could naturally prolong the elevated temperature curve. But the important differentiation between this patient's temperature and the one seen in myocardial infarction is the fact that the spiking temperature exhibited in this case was evidence of a bacterial infection, whereas myocardial infarctions have a sustained elevated temperature. Furthermore, progressive myocardial infarction would exhibit progressive electrocardiographic changes, which, if I am correct, were not present in this case. I believe we have demonstrated that myocardial infarction could not very well have been the cause for the spiking temperature and that we have deducted a bacterial infection to be the underlying factor. This bacterial infection was found at microscopic examination to be an acute hematogenous tuberculosis involving the lungs, liver, and spleen.

During the last three years I had occasion to observe 3 cases in which old people—1, 87 years of age, the others, 71 and 69 years, respectively—at necropsy showed acute hematogenous tuberculosis involving many of the parenchymal organs. The first case at necropsy presented easily recognizable miliary tubercles throughout the parenchymal organs. It took us three hours to demonstrate the source of dissemination. The only, and I stress the only, caseous necrotic focus was one lymph node surrounding the thoracic duct at the level of the first lumbar vertebra. This lymph node had perforated into the thoracic

duct, and this caused the acute lymphohematogenous dissemination. The second case suffered for five years from pain in the lower part of the back which was diagnosed repeatedly as hypertrophic osteoarthritis of the lower spine. In this case at necropsy, the only demonstrable caseous necrotic area was found to be the second lumbar vertebra, which served as focus for an acute hematogenous dissemination. In the third case, a caseous necrotic prostatitis was the course from which the tubercle bacilli found their way into the blood stream. Clinically, in the first 2 cases the diagnosis of miliary tuberculosis was missed completely, whereas in the third case a tuberculous meningitis revealed the true character of the underlying pathology—but, even here, the focus of dissemination was not determined until necropsy. In our case we were unable to demonstrate a caseous necrotic focus that could have given rise to the hematogenous dissemination, but no doubt it existed. We just missed it.

In concluding, I should like to say that it is naturally difficult to make the diagnosis of miliary tuberculosis in the absence of obvious pulmonary tuberculosis but that its occurrence is by no means rare in the old-age group.

Anatomic Diagnosis

- | | |
|------------------|--|
| <i>Primary</i> | Myocardial infarction due to coronary insufficiency
Acute hematogenous tuberculosis involving lungs, liver, and spleen, primary focus unknown |
| <i>Secondary</i> | |
| <i>Heart</i> | Left ventricular hypertrophy and dilatation, moderate coronary atherosclerosis, moderate pericardial effusion, mural thrombus, left ventricle |
| <i>Lungs</i> | Pulmonary edema and congestion, acute bronchitis, right, fibrous pleural adhesions, right |
| <i>Aorta</i> | Moderate atherosclerosis |

For the most part, American doctors are determinedly opposed to this drive for socialized medicine, and I must say I am with them all the way. State medicine, in my opinion, bears disaster for doctor and patient alike. You cannot pipe out medicine to the community as you do with steam heat.—*Dr. A. J. Cronin, English Author of "The Citadel"*

According to *Science Service*, the U. S. Navy is shipping to Cuba a new 500-bed mobile hospital that will be rushed to any outpost in the Western Hemisphere where American fighting forces may need hospital care. The staff will include thirty medical officers and 300 enlisted men of the Navy.

The Pathology of the Premature Infant

The pathology of the prematurely born infant constitutes but one chapter in human pathology. Except for certain disease states conditioned by the immaturity of the organism and by the factors peculiar to intrauterine existence and the act of delivery, pathologic changes in the prematurely born baby are much the same as those in the full-term neonate and in the older individual. No satisfactory statement can be made concerning the cause of death unless a complete gross and microscopic postmortem examination supplemented by indicated bacteriologic and even chemical studies is carried out, no matter what the size of the infant. Prematurity is not an acceptable cause of death. Anatomic immaturity of organs and tissues—such as may be demonstrated, for example, in the lungs, central nervous system, the pancreas, and the kidneys—may be correlated with recent physiologic studies and should indicate the direction for further important research.

Pathologic changes may be divided into those that characterize the neonatal and the postnatal periods. For the purposes of this discussion a lantern-slide demonstration is made of gross and microscopic alterations in the prematurely born infant with particular reference to (1) atelectasis, the cause of which must be demonstrated in every case, (2) aspiration of contents of the amniotic sac, (3) hemorrhage, gross or petechial in character, occurring mainly in the central nervous sys-

tem, lungs, gastrointestinal tract, and skin,

(4) acute infections, such as pneumonia, occurring secondary to aspiration of infected amniotic sac contents, omphalitis, and skin infections or after exposure to infections of the upper part of the respiratory tract after birth, and (5) congenital anomalies. Attention is paid to several special questions. Chronic inflammatory process may be present at birth as a mark of intrauterine infection. Kernicterus occurs more frequently, erythroblastosis fetalis less so, in the premature than in the full-term infant. Pulmonary edema is an important cause of death of both the premature neonate and the older premature infant.

A few general suggestions appear to be pertinent to this discussion. The pathology of the premature infant should be regarded not as a task to be relegated to a young clinician marking time while waiting for a clinical appointment or to the most inexperienced member of the department of pathology but as one of the important and intriguing divisions of human pathology. Postmortem examination, pathologic interpretation, and research in this field are among the many responsibilities of the trained pathologist. Advances can be made only on the basis of knowledge concerning the anatomic and physiologic peculiarities of the prematurely born infant and familiarity with the obstetric and pediatric problems involved.

The Chicago Plan for the Reduction of Infant Mortality Dr Edith L Potter (*by invitation*), Chicago

For the past several years the members of the medical profession and the Health Department in the City of Chicago have carried

on an active program designed to lower the infant mortality rate. Early in the program, an extensive autopsy study of infants less

than 1 year of age was instituted in order that accurate information concerning the relative importance of various factors causing death might be available for a basis on which to plan a course of procedure. This study is still in progress and is a valuable educational portion of the program. Prematurity, birth trauma, and infections are the three major fields into which effort has been directed.

Approximately two-thirds of the infants in Chicago who succumb under 2 weeks of age and over one-third of all of those who die under 1 year of age are premature at birth. The care of premature infants has been improved, and for several years all have been housed in adequately equipped and conducted nurseries until normal birth weight has been attained and until they have demonstrated their ability to maintain an independent existence in a world devoid of incubators, oxygen, and other special appliances.

The second most common cause of death is birth trauma and, in an attempt to cope with this problem, measures designed to modify in some degree the practice of obstetrics have been instituted. The most important was the establishment by the hospitals of definite obstetric staffs and the provision for consultation for doctors who are

not specialists in obstetrics. An attempt has been made to improve the general level of obstetric practice through various educational channels.

Infections are an important cause of stillbirths and maternal deaths as well as of infant deaths. Measures directed toward limiting the possibility of infection of the mother during or after delivery and of the infant after birth consist in the required isolation from the rest of the hospital of obstetric and newborn units and the maintenance in each of a strictly aseptic technic.

All procedures that have been put into effect have been recommended by the Joint Maternal Welfare Committee of Cook County, which is composed of members from all of the societies in Chicago concerned with the care of obstetric or pediatric patients or with hospital management.

The infant death rate (under 1 year) in Chicago has decreased from 124 per 1,000 live births in 1916 to 28.8 in 1940, under 1 month, from 26.1 in 1925 to 20.3 in 1940, and under 1 day, from 13.9 in 1916 to 10.4 in 1940. The mortality rate for premature infants was 37 per cent in 1935, the first entire year in which all premature births were reported, and had dropped to 19 per cent in 1940.

Discussion of Papers by Drs Farber and Potter

DR RUSTIN MCINTOSH: It is a great privilege to bear these two contributions by such distinguished workers. I do not suppose that we can claim that the entire interest in the pathology of premature and newborn infants in the United States is focused here, but I do know that the leading lights and the most incandescent enthusiasts in this country in that field are present.

No clinician can be satisfied with the morphologic approach alone and, while I agree with Dr Farber when he tells us that we must not be content to assign prematurity as a cause of death without pressing our inquiry further, nevertheless it seems to me that the chief function—the function most important to the pediatrician—of the careful anatomic studies now being made under the leadership of such able demonstrators as Dr Farber and Dr Potter is to furnish us signposts, direction finders, that will point the way back to the underlying disturbances of physiologic mechanisms. Anatomic end results often represent the final and irremediable product of disturbances which, if taken in

hand at an earlier stage, might have been brought under therapeutic or even prophylactic control. It is through a proper choice of such measures and through their application during the stage of functional derangement that one may hope to effect a reduction of premature and neonatal mortality.

Dr Potter points out that the chief lines of attack on neonatal mortality rates lie in the prevention of premature delivery, of trauma, and of infections. The whole question of nutrition has also, it seems to me, become much more important than it ever seemed before and has taken on new aspects. It is no longer a question merely of the provision of an adequate supply of food energy as calories. Under the influence of Dr Samuel Levine and his collaborators we have learned new facts about the water requirements of premature infants. Closely related is the problem of how a young infant, taking a mixed diet of electrolytes, can select what he needs for proper growth and metabolism and deal adequately with the excretion of the remainder. The whole vitamin

question has also been thrown into prominence. One reference has been made, from morphologic evidence, to the possibility of scurvy arising in the premature infant, we know that serum analyses during life have shown that premature infants are apt to suffer a quick lowering of their blood level of ascorbic acid, and, again, Dr Levine has demonstrated that their inability to prevent the excretion of a certain aromatic compound can be controlled by the administration of vitamin C. Vitamin K is also of outstanding importance, many of the workers with a good deal of experience in this field and who speak with considerable authority take a different point of view from that of Dr Farber with regard to the relationship of intracranial hemorrhage in the premature infant to vitamin K deficiency. These are only a few examples. The number of problems is vast, and their scope can only be hinted at. The important thing is the angle of approach, which justifies the hope that gratifying results will come through appropriate study.

It is obvious that Chicago has made great progress in lowering the incidence of premature and neonatal deaths. Here in New York we have a great deal to learn. We are organizing, and I hope that discussion will be forthcoming here from those who represent the Committee on Prematurity. It has been extremely interesting to hear the papers, and I wish to voice my thanks to both the speakers.

DR BERYL H. PAIGE. It is rare indeed for members of the New York Pathological Society to hear a survey of such a large group of cases as these two papers represent. In this vicinity, autopsies on newly born infants are done in some hospitals in the department of general pathology, and in other hospitals they are done by the department of obstetrics and gynecology. Consequently among the audience there are those to whom this age group is of special interest. These pathologists are, I am sure, especially appreciative of the interesting presentations and the excellent demonstrations that have been shown. To the pathologists whose services are limited to older age groups it is evident that newly born infants and the pathologic lesions found in them represent a more or less specialized study.

As has been stressed, a thorough autopsy is extremely important, and it has been indicated that the methods used must be somewhat modified from those used in older patients. This I think is an important point. For instance, failure to employ proper methods

in examining the cranial cavity may give rise to such damage to the tentorium, the dural sinuses, and the brain itself that it may not be possible to evaluate the true pathologic conditions so that the autopsy may be worthless and useless for statistical studies. The emphasis that Dr Farber has placed on the lung indicates that no autopsy can be considered complete until a microscopic examination of the lung has been done. The lesions described bring to the minds of many of us the papers that Dr Johnson, pathologist to the Sloane Hospital, presented at the meetings of the pathologic and obstetric societies years ago. Some of you here may remember that he first presented a series of 4 premature infants with lesions in the lungs similar to those found in influenza, especially in the presence of a hyaline membrane. Within the year he realized it was due to the aspiration of amniotic contents. In his second paper he analyzed cases of congenital pneumonia and drew conclusions regarding the obstetric complications that result in fetal asphyxia and in the aspiration of large amounts of amniotic fluid into the lungs and the relationship of infection of the amniotic contents to antenatal pneumonia. These papers did much to stimulate interest in the lungs of newborn infants in New York and vicinity. After hearing Dr Farber's discussion on immaturity, atelectasis, and lesions resulting from aspiration of amniotic contents, I think that Dr Johnson can no longer say, as he did in 1924, that the newborn lung requires much additional study.

The recognition of a low concentration of prothrombin in the blood of the newly born is interesting in connection with this group where hemorrhages are so extensive but, as the previous speakers have said, we still have to wait to see what the results will be.

Dr Farber has covered the other significant pathologic findings in the newly born. I should like to add a comment on one condition in antenatal and postnatal life which has been of interest to us—that is a condition that Dr Potter mentioned—toxoplasmosis. Most of you recall the recent paper by Drs Pinkerton and Henderson in the *Journal of the American Medical Association* on "Adult Toxoplasmosis," a disease resembling Rocky Mountain spotted fever in some of its clinical manifestations. In the same journal Dr Sabin reported instances of atypical encephalitis in children, 6 and 8 years old, due to the organism, *Toxoplasma*. Up to the present time this organism has been found most fre-

than 1 year of age was instituted in order that accurate information concerning the relative importance of various factors causing death might be available for a basis on which to plan a course of procedure. This study is still in progress and is a valuable educational portion of the program. Prematurity, birth trauma, and infections are the three major factors into which effort has been directed.

Approximately two-thirds of the infants in Chicago who succumb under 2 weeks of age and over one-third of all of those who die under 1 year of age are premature at birth. The care of premature infants has been improved, and for several years all have been housed in adequately equipped and conducted nurseries until normal birth weight has been attained and until they have demonstrated their ability to maintain an independent existence in a world devoid of incubators, oxygen, and other special appliances.

The second most common cause of death is birth trauma and, in an attempt to cope with this problem, measures designed to modify in some degree the practice of obstetrics have been instituted. The most important was the establishment by the hospitals of definite obstetric staffs and the provision for consultation for doctors who are

not specialists in obstetrics. An attempt has been made to improve the general level of obstetric practice through various educational channels.

Infections are an important cause of stillbirths and maternal deaths as well as of infant deaths. Measures directed toward limiting the possibility of infection of the mother during or after delivery and of the infant after birth consist in the required isolation from the rest of the hospital of obstetric and newborn units and the maintenance in each of a strictly aseptic technic.

All procedures that have been put into effect have been recommended by the Joint Maternal Welfare Committee of Cook County, which is composed of members from all of the societies in Chicago concerned with the care of obstetric or pediatric patients or with hospital management.

The mortality rate for premature infants was 37 per cent in 1935, the first entire year in which all premature births were reported, and had dropped to 19 per cent in 1940.

Discussion of Papers by Drs Farber and Potter

DR RUSTIN MCINTOSH. It is a great privilege to hear these two contributions by such distinguished workers. I do not suppose that we can claim that the entire interest in the pathology of premature and newborn infants in the United States is focused here, but I do know that the leading lights and the most incandescent enthusiasts in this country in that field are present.

No clinician can be satisfied with the morphologic approach alone and, while I agree with Dr Farber when he tells us that we must not be content to assign prematurity as a cause of death without pressing our inquiry further, nevertheless it seems to me that the chief function—the function most important to the pediatrician—of the careful anatomic studies now being made under the leadership of such able demonstrators as Dr Farber and Dr Potter is to furnish us signposts, direction finders, that will point the way back to the underlying disturbances of physiologic mechanisms. Anatomic end results often represent the final and irremediable product of disturbances which, if taken in

hand at an earlier stage, might have been brought under therapeutic or even prophylactic control. It is through a proper choice of such measures and through their application during the stage of functional derangement that one may hope to effect a reduction of premature and neonatal mortality.

Dr Potter points out that the chief lines of attack on neonatal mortality rates lie in the prevention of premature delivery, of trauma, and of infections. The whole question of nutrition has also, it seems to me, become much more important than it ever seemed before and has taken on new aspects. It is no longer a question merely of the provision of an adequate supply of food energy as calories. Under the influence of Dr Samuel Levine and his collaborators we have learned new facts about the water requirements of premature infants. Closely related is the problem of how a young infant, taking a mixed diet of electrolytes, can select what he needs for proper growth and metabolism and deal adequately with the excretion of the remainder. The whole vitamin

I was greatly interested in Dr Farber's paper, and particularly interested in two of the points that he brought out one, the question of hemorrhage in the premature I find that most premature autopsies are marked by hemorrhage in some degree and very often by hemorrhage in the brain, subarachnoid membrane, and subventricular areas It seems almost certain that the premature vascular system is not able to withstand the forces with which it is brought in contact during labor and that, as a result of the poorly developed vascular system, we find these hemorrhages developing It is for this reason that I believe it is of extreme importance that we should shorten premature labor and avoid any compression of the premature fetus in the second stage with due regard to the safety of the mother I also have no means of proving this yet, but I feel in definite agreement with Dr Farber that it is quite unlikely that vitamin K will prove of much value in preventing this type of premature hemorrhage I do not believe such hemorrhage has much to do with the ability of the blood to clot but is rather due to a definite weakness of the vessel wall

Second, I was interested in some of the specimens Dr Farber showed of the premature lungs, particularly one which he termed aspiration of vernix caseosa It showed a quite definite thick layer of material lining the alveolar ducts and plugging the alveolar spaces This is the type of lesion that the late Dr Johnson, whose name we have heard many times here, termed "hyaline membrane of the lung," and I wonder if Dr Farber has any explanation as to why this material looks so different from the usual material that is aspirated into the fetal lung during labor

Finally, I should like to express my complete agreement with Dr Farber that the presence of any large amount of amniotic residue in the lung is almost certain evidence that the baby has suffered some degree of asphyxia

Dr SIDNEY FARBER Dr McIntosh raised a question concerning the importance of vitamin K in preventing hemorrhages in the premature infant My own experience is not great enough to permit a definite answer at this time I do not believe, however, that vitamin K will prevent the initial large hem-

orrhage caused by the rupture of a dilated, bridging cerebral vein Vitamin K might be expected to have an important effect in preventing a continued oozing or bleeding after rupture of small vessels Until the accumulation of sufficient data permits an answer to this question, I would prefer to answer as I did because of the danger that vitamin K administration to the mother and to the infant may be regarded as a substitute for the special obstetric and pediatric measures required for the successful care and prevention of hemorrhage in the prematurely born baby

In thanking you again for this opportunity to speak on the pathology of the premature infant, I wish to say one last word concerning this problem. It appears clear that if the conclusions that Dr Potter and those of you who have been trying to reduce the mortality of the prematurely born infant have reached are put into practice by all who have the responsibility for the delivery and care of premature babies an immediate and important reduction in premature mortality would be achieved I do not have to be a prophet to predict that when that day comes a large number of problems of great interest and importance in the physiology and pathology of the premature baby will be encountered Once again, the results of carefully performed postmortem examinations closely allied with clinical and physiologic observations will be needed to point the way for further research Here we have an illustration of what Dr Wolbach might have had in mind when, to a clinical friend who remarked "morphology is dead—all the morphologic problems have been solved," he replied in characteristic fashion "Yes—all the simple problems have been solved"

Dr EDITH POTTER I wish to thank you for permitting me to address this society A program that is a success in one community may need to be considerably modified to meet with equal success in another location, and no one plan can be universally applied The principal condition required to decrease morbidity and mortality among mothers and infants is an awareness that problems exist which in a large measure are capable of solution New York is doing an admirable piece of work, and I wish you continued success

"If people knew how hard I have had to work to gain my mastery, it wouldn't seem wonderful at all."

The answers to questions [page 2031] were, 1—e, 2—e, 3—b, 4—d, 5—e, 6—d, 7—e, 8—d, and 9—c

quently in young infants, in whom it gives rise to extensive encephalomyelitis and chorioretinitis. The onset of symptoms and signs in some of these patients during the first 2 or 3 days of life has led to the diagnoses of birth injury, congenital hydrocephalus, or convulsions of undetermined etiology. In other infants hydrocephalus has developed gradually to reach a moderate degree at the end of the first month. Lesions in the fundi have presented difficulty in identification and have been looked on variously as atypical retinoblastomas or unusual forms of chorioretinitis. A diagnostic feature of some importance in the disease is due to the fact that calcium is deposited early in the necrotizing and inflammatory lesions in the brain and is demonstrable by roentgenologic examination. In 1 patient, intracranial calcification was so demonstrated during the second week of life and, in another, heavy deposits of calcium were found at the end of the first month when the first roentgenograms were taken.

Until recently, we have been of the opinion that the disease terminated fatally, usually in early infancy, but identification of 2 cases in older children, still alive, shows that the eventual course in some patients is still unknown.

The early onset of symptoms and the demonstration of calcification of lesions so soon after birth suggested that the parasitic infection was active during intrauterine life, and this was proved to be true by a case that Dr Watson has kindly allowed us to include in our study. Roentgenograms of the mother, taken late in pregnancy, suggested hydrocephalus in the fetus, and eventually craniotomy was required for delivery. In this still-born, hydrocephalic fetus, encephalitis was advanced and in some sites had undergone calcification. There were also characteristic myelitis and chorioretinitis. Parasites were numerous in the lesions and also in the heart, adrenals, and striated muscles. Numerous sections from the placenta failed to show organisms, and none could be recovered from the mother. She and the mothers of the other infected infants knew of no unusual diseases during their lives.

From what source and by what route Toxoplasma reaches the fetal brain remains to be determined, and some pathologist interested in the pathology of the premature infant will in the future contribute much to the knowledge of the infantile disease by identifying the disease in its incipient stage.

DR WILLIAM E. STUDDIFORD Dr Potter

has presented to us an admirable plan for the study of stillbirths, neonatal deaths, and deaths in infants under 1 year taking place in a large community. This plan has been carried out in Chicago for the past several years so that the vast amount of material available in such a community has been almost fully utilized. She has emphasized not only the importance of the autopsy but the correlation of the findings at autopsy with the clinical background. Such a correlation is of particular importance to the obstetrician in the group of cases consisting of stillbirths and neonatal deaths and to the pediatrician in the group of infants up to 1 year of age. It has been pointed out that comparatively little improvement has been brought about in the latter group.

Many institutions in New York are doing fine work along these lines, but such efforts are isolated. We do not as yet have any special system of coordination such as has been described in Chicago. I am sure that the various committees working in this field are making serious efforts to bring such a plan about and to equal the results we have seen here.

In reviewing a much smaller quantity of material than has been reported by Dr Potter—namely, the autopsies seen at Bellevue Hospital—we can fully agree on the causes of death in these three groups. I think Dr Potter has been quite kind to the obstetrician in discussing the methods of attack on the main causes of death: prematurity, intracranial injury, and infection. She devoted most of her time to the care of the premature infant after it was born, but prematurity, certainly to some extent, is the problem of the obstetrician. It is probable that a certain amount of prematurity can be prevented by proper antepartum care. Although some are inevitable, a certain number of premature births initiated by premature rupture of the membranes can be postponed. Once labor has commenced it has been fairly well shown that the use of sedation of any kind works greatly against the interests of the fetus. Finally, we should deliver these babies with the least possible trauma. If the obstetrician will work along these lines he will hand the premature baby over to the pediatricians in the best possible condition.

I do not believe there can be any discussion of Dr Potter's remarks on the methods to reduce the incidence of intracranial injury nor of her remarks on the efforts to reduce the possibility of infection.

L. A. Chambers* of the University of Pennsylvania on curd digestion in an artificial digestion apparatus. In these studies they give the approximate range of curd size expressed in total surface for various kinds of milks used in infant feeding. Dr Wolman¹⁰ has used, with most satisfactory results in the feeding of infants at the Children's Hospital of Philadelphia, a low curd tension milk prepared by the sonic wave process.[†]

In view of the activity in the milk industry today in pushing the preparation of soft curd milk by various methods, including pressure homogenization, as well as the increasing interest on the part of the medical profession in processed milks of various types, particularly evaporated milk, there has arisen a challenge that Certified Milk could not overlook.

By reason of the increasing prominence and general acceptance of the teachings of Dr Brennemann and his associates, the work of Drs Wolman and Chambers, and others, the matter seemed deserving of the most careful attention and consideration on the part of the Milk Commission.

Certified Milk seemed the best source for a soft curd milk. It was felt that a processed milk produced from Certified would go a long way in meeting this ideal of a milk for infant feeding in that (1) it would be a milk of low curd tension produced from the highest grade of milk in the dairy industry, (2) it would be processed after milking at the point of production and immediately bottled, (3) it would be a processed milk that the profession would know was subject to the same methods and standards under which Certified Milk is produced, (4) the milk used in its preparation would be the cleanest, freshest, most nutritious, as well as the lowest bacteria count milk available in the dairy industry—a milk obtained from cows in an optimal state of

health and hygiene and freedom from tuberculosis.

Therefore, using Certified Milk as a basis and employing a process for inducing a soft curd milk which would add nothing to the milk and take nothing away from it, we should theoretically have a rather ideal milk for infant feeding—a milk in which no preliminary preparation would be necessary—a milk that the physician might use as the base for the feeding formula with such dilution or addition as might be prescribed.

Because of the curd tension of Certified Milk in its natural state, preliminary boiling is desirable to render it more easily digested by the average infant stomach, especially for the very young and more particularly for prematures. This preliminary boiling in making the formula in the home quite readily prepares the milk for use in routine infant feeding, and, as the article¹¹ in the *Journal of the American Medical Association* of June 19, 1937,* states, there is meager evidence that any soft curd milks are better digested or more completely digested than ordinary boiled milk. Despite the simplicity of this procedure for preparation of milk formulas, the practitioner may have trouble using milk in feeding babies under his care because of lack of sufficiently long boiling or no boiling at all.

There is not one processed milk available in the market for infant feeding in which proof has been submitted that the milk used in its preparation meets the same high standards for purity, nutrition, and cleanliness, and safeguards as to production and freshness as does Certified Milk.

It appeared clear that if a milk could be prepared by a process that would maintain and safeguard the excellent qualities of Certified Milk and yet provide a more readily digestible curd a real contribution might be made to the practitioner's feeding problems.

On this basis preliminary investigation of the possibility of the production of a low curd tension milk from Certified was undertaken. After consideration of the pressure homogenization procedure and the sonic oscillation process, it was decided that the latter method would comply with the requirement for Certified Milk in that nothing would be added to or taken away from the milk as produced by the cow, because in the sonic oscillation process reduction of curd tension is accomplished without any other known change in the milk.[†]

The preliminary steps and investigations made were currently reported upon at Milk Commission meetings. The apparatus manufactured by the Submarine Signal Company of Boston for the production of a soft curd milk was installed on experimental production at Loudon Hill Farm, South Montrose, Pennsylvania, with the approval of the Department of Health. An experimental study period of a clinical type was decided on. The Milk Commission appointed a committee to conduct the study of the product. A plan was prepared, forms were mimeographed,

* In Dr Wolman's work the curds of raw processed and modified milks were measured after carefully controlled digestion of these milks in an artificial digestion apparatus using a synthetic gastric juice. The coagulated material then was passed through a series of graded wire sieves of meshes ranging from 1/4 to 1/64 inch. Filter paper collected the finest particles. After weighing it is possible to make an estimate of the total surface.

† More recently in a report on a comparative study of soft curd homogenized milks produced by various methods Dr Wolman gives data concerning the curd tension of different milks. The high-pressure homogenized milk gave readings of 5 to 20 Gm. the low-pressure homogenized milk and the sonized milk a range between 10 and 30 Gm. the former giving higher readings. The raw milk unboiled tested 40 to 60 Gm. and if boiled five minutes 5 to 10 Gm. He considers that pasteurized homogenized milks are as good or better as a food than pasteurized milk boiled five minutes in the home and that the process possesses the advantage of making less any danger of household contamination of the food. In a table giving the number of loose bowel movements with each of these for varieties of milk, the following episodes of loose bowel movements with or without vomiting occurred: pasteurized milk boiled five minutes at home 77; sonized milk 28; low-pressure homogenized milk, 76; high-pressure homogenized milk 44 (reference: Soft Curd Homogenized Milk in Infant Feeding, Preliminary Report by Dr Irving J. Wolman in the *Weekly Roster and Medical Digest* the Philadelphia Medical Society April 6 1940, p. 1000).

The Committee wishes to draw attention in this connection to the low curd tension readings noted in the present study of Sonized Certified Milk which average 10.5 Gm. and which appear lower than those reported by Dr Wolman. The almost complete absence of loose bowel movements in our series except when associated with respiratory infection is in accord with the lower incidence with this milk as reported by Dr Wolman.

* The article on "The Nutritional Significance of the Curd Tension on Milk" appeared as an authorized publication of the Council of Foods.¹¹ This article is most informative and was freely drawn on by the Committee both during its work and in formulating the report.

† It appears from our present knowledge that no changes occur in the process of sonic oscillation other than those that may be incidental to the pasteurization that precedes the processing.

A STUDY OF SONIZED SOFT CURD MILK PREPARED FROM CERTIFIED MILK*

Part 1—The Theoretic and Clinical Basis for the Study and Use of a Low Curd Tension Milk Prepared from Certified Milk

For the fundamental reasons that have given the present prominence and importance to the use of homogenized milk in the feeding of infants, reference is necessary to the publications of Dr. Joseph Brennemann,¹ of Chicago. In this work particular attention is drawn to the difference in the character of the curd which raw and treated cow's milk forms in the infant's stomach.

In subsequent publications and again most recently in his *Practice of Pediatrics* in the chapter on "Artificial Feeding of Infants," Dr. Brennemann² in comparing bovine and human milk has called attention to certain differences between the protein and fat of these two milks. These it would seem may be correlated to explain the relative digestibility of the milks and the differences in the character of the curd which they form in the infant's stomach.

It is recognized that the fat of cow's milk is not as readily and fully utilized as that of breast milk. This is apparently dependent on factors other than the fat, in particular the physicochemical characteristics of the medium in which it is contained. Thus, there are certain striking differences between the two milks relative to their protein content and its distribution in the respective forms of lactalbumin and casein. Thus, while in human milk the casein content averages 0.5 per cent and the lactalbumin 0.75 per cent, in cow's milk the casein is 3.0 per cent and the lactalbumin is 0.5 per cent. Hence, in digestion, owing in large part no doubt to the much smaller amount of casein and the fact that lactalbumin does not coagulate in the stomach, human milk remains nearly a liquid, forming fine soft curds

in the infant's stomach, while cow's milk, owing to its sixfold greater casein content, coagulates to form one or more large clots.

This type of curd offers considerable hindrance to access of the digestive juices of the stomach and, therefore, leaves the stomach much more slowly. While this is mainly due to the large casein curds that are formed, it may also possibly be attributed in part to the character of the fat. Therefore, a most important consideration in the feeding of cow's milk formula is its adequate preparation by some means that will insure a finer, softer, more readily digested curd. In fact, "such a process of attenuation of the curd of cow's milk has been intentionally or unintentionally a major factor in the preparation of every infant's food that has ever been devised."³

The effect of dilution, boiling, acidification, and alkalization, the removal of calcium, and the addition of cereal water have all resulted in the production of a finer, softer curd more nearly approaching that of human milk. Most all processed milks for infant feeding have intentionally or unintentionally a finer, softer curd. In explanation of whatever values are claimed for these various milks in infant feeding, the factor of lowered curd tension is a consideration that should not be lost sight of.

There is no question that the popularity that certain processed milks have with a large group of the medical profession is concerned in practical application with the simplicity and ease with which milk of this kind may usually be fed to the average infant without exciting digestive troubles. Here again one must not be forgetful of the fact that this ease of digestibility relates especially to the changes that the process used has induced, thus lowering the curd tension of the milk. It is doubtful whether the profession as a whole has as yet a correct appreciation of this fundamental fact. As a matter of fact, since the early experiments of Brennemann demonstrating the different curd qualities of raw and treated milks, the character of the curd which the milk forms in the infant's stomach has been generally recognized as an important factor in its digestibility.

There has recently been introduced into the preparation of milk, particularly for infant feeding, a process termed homogenization^{4,5,6} in which, by means of mechanical subdivision of the fat particles to smaller, more uniform size, there results a milk in which there occurs a curd tension lowering proportional to the reduction in size of the fat globules. A second process for producing a milk of low curd tension is known as the sonic process. In this method the milk is passed slowly at no pressure over a magnetically driven plate vibrating intensely with the frequency of sound waves. Effective curd tension lowering results.

In this connection, there are also the interesting studies^{7,8} of Dr. Irving J. Wolman and Dr.

* This report was made for the Milk Commission of the Medical Society of the County of Kings by a Special Committee (see below). It was submitted to the Department of Health, New York City on February 1, 1940, following an experimental study of the milk from April 1, 1939 to January 15, 1940.

As presented now for publication, this paper is almost a facsimile of that sent to the Health Department with the exception that the bibliography has been revised certain footnotes have been included, and the laboratory analyses of individual milk samples have been placed in summary forms in appropriate tables. In the planning and execution of this study, the Committee expresses its indebtedness for the constant guidance and invaluable advice given by Dr. Alec N. Thomson, secretary of the Milk Commission.

The following physicians have cooperated by registering cases with the Committee: Drs. Harold L. Barnes, Manning Field, Charles F. Fisher, Clarence Friedman, William Z. Fradkin, Thurman B. Givan, Lewis A. Koch, Abraham Litvak, Philip Lombard, Emil Smith, and Benjamin Stollhoff.

For assistance with the technical laboratory examinations we express appreciation to Mrs. Evelyn Crabb for her valuable cooperation and for assistance with records and reports our acknowledgment is due to Miss Nabel T. Fisher.

Respectfully submitted, Harry S. Bikoff, M.D.
Samuel S. Brown, M.D. Edward W. Zukauskas, M.D.
Joseph C. Regan, M.D. Chairman

Infants' Percentile Weight Chart

FIG 1 This is known as a Percentile Weight Chart and may be used to advantage in following the growth and nutrition of normal infants throughout the first year. It is recommended that the baby be weighed regularly once each week at bath time and that the weight be recorded on this chart. When the points represented by these weights are joined together, a weight curve for the infant will be formed, and the nature of this curve will give valuable information as to health and nutrition.

A normal infant receiving a satisfactory diet will be expected to follow quite closely in weight one or another of the curves shown in the chart. Failure to keep up with the line previously followed or rapid gain beyond it suggests the need for change in diet and should be brought to the attention of your physician.

Normal infants of the same age differ in body build and hence in weight. The weight of 80 per cent of normal infants will fall between the 90 and 10 per cent lines on the Percentile Chart (shaded area). If a baby's weight falls below the 10 per cent line or rises above the 90 per cent line, progress is unusual and requires attention. Regular progress within the shaded area suggests that the infant is well nourished and making satisfactory progress.

The measurements upon which this chart is based were obtained on a small series of normal full-term babies born at the Boston Lyng-in Hospital and carefully followed throughout the first year. Small prematurely born or otherwise exceptional babies should not be expected to conform to the pattern of this chart.

TABLE 3—AVERAGE WEIGHT GAINS PER WEEK ACCORDING TO AGE GROUPS

Age	Number of Infants	Average Gain per Week, Ounces	Low, Ounces	High, Ounces
Under 6 mo.	16	5.6	3.1	10.0
6 mo.-1 yr *	3	2.7	2.6	2.9
1 yr -1 1/2 yr *	2	5.3	2.3	3.3
1 1/2 yr -2 yr	0			
Over 2 yr	1	4.0		

* The number of infants between 6 months and 1 year, and 1 year and 18 months included in the series is too small to consider the average gain per week as given in this table as an index of what would actually be the case with a larger series of cases.

time to give a clear-cut pattern of what effect the milk may have on weight increment.

We have attempted to analyze the weights recorded in several ways: (1) according to the Infants' Percentile Weight Chart of Cambridge Hospital, Cambridge, Massachusetts (Fig. 1), (2) in accordance with the ounces gained per

in a third group designated as Group C. The patients were not formally registered in the Commission office with any history forms. The results from the cooperating physicians as expressed in telephone or written reports will, therefore, be briefly mentioned.

It is rather difficult to determine in such a small series the significance of weight increment that occurred in the cases on this milk. The infants in the group under 1 year were too few in number and some were on the milk too short a

* The clinical study of these cases as evidenced in the statistical summary clearly indicates that in nearly all instances where infants with signs of curd indigestion were placed on this milk there was rapid improvement and disappearance of the symptoms of colic, abdominal distention, regurgitation, vomiting, crying, restlessness, etc. It may safely be said that sonized Certified Milk is an easily digested milk.

and a laboratory study as to curd tension, bacterial counts, fat content, as well as clinical results of the use of this milk in private practice, was begun in April, 1939.

The results so far as laboratory reports of the examination of this milk at the Milk Commission's laboratory, bacterial counts, butterfat content, and curd tension readings are concerned have exceeded our expectations and are available in the accompanying reports. As to the clinical results, the reports filed by the cooperating physicians who have made observations of infants fed with this milk are herein presented, as well as the impressions arrived at as to the value of this milk.

The practitioner should be made aware of the fact that a soft curd milk produced by the sonic oscillation process from Certified, with a wonderfully good taste, a low curd tension, remarkably

TABLE 2—WEIGHT GAINS BEFORE AND AFTER USING SONIZED CERTIFIED MILK

32		

* It is apparent that while the case numbers range from 1 to 32 there are only 22 patients listed. This discrepancy is not real however but is explainable in the fact that in 3 patients originally registered with a case number no follow-up examinations were made by the cooperating physician and, therefore, they are included in Group B. In 7 other patients, although they were registered and received their proper numerical designation, no history or physical examination forms were filed with the Commission and therefore, they necessarily had to be excluded from Group A.

low bacterial count, and normal butterfat content, is available for infant feeding. The milk deserves a high place in the physician's dietetic armamentarium.

Part 2—Clinical Study of Sonized Certified Milk as Used in Private Practice

After the plan of study had been drawn up, the forms for physical examination of the infant were prepared, and the Loudon Hill Farm at South Montrose, Pennsylvania, was inspected by a visit of representatives from the Commission. The operation of the sonic oscillator was critically observed, and samples of the milk in various parts of the process from the pasteurizer to the cooler were examined on many occasions. On the basis of the excellent results found in the laboratory tests for curd tension, bacterial counts, fat content, etc., the clinical study was begun. The cases for study were registered in the Milk Commission office through the secretary-stenographer of the Subcommittee.

From April 8, 1939, when the first case was registered, until January 15, 1940, when the study period was ended, a total of 25 cases was registered. In 22 of these the history, physical examination, and follow-up forms were made out and the findings could, therefore, be tabulated. This group is the main one on which the tabulated study of results could be made and is designated as Group A (Table 1). The remaining cases without sufficient follow-up examination data are designated as Group B. In these 3 cases the cooperating physicians expressed their opinion as to the results obtained with sonized Certified Milk.

Sonized Certified Milk was supplied and used

amination follow-up forms, all 18 infants who could be studied by virtue of their ages according to this method were well nourished and made satisfactory progress except 1. Of the remaining 6 infants as judged by their weight gains, progress was satisfactory in all. In 3 of the 6, detailed follow-up was carried out. In the remaining 3 there was insufficient data but the physicians summarized their opinions as satisfactory.

The stools of all infants placed on this milk were satisfactory. Constipation, if any was present before, appeared to diminish or disappear after this milk was used. In 3 cases curds and mucus were mentioned as being present in the stools prior to the use of sonized milk, and these disappeared after its use. In no instance did loose stools develop while on sonized Certified Milk in the absence of an acute infection of the upper part of the respiratory tract. In a few instances when an acute infection of the upper part of the respiratory tract occurred, some loose stools were present. These, however, disappeared quickly. It was found during the study that it was unnecessary to stop sonized Certified Milk in the presence of infections of the respiratory tract.

In recognizing the difficulty of drawing conclusions from comparison of weights, the Subcommittee using Fig 1 was interested to see whether the cases registered (16) could be considered normal and whether the cases reported by Dr Wolman of Philadelphia (10) remained within the grouping of the percentile lines. Arbitrarily and for the purposes of tabulation, the 10 to 25 per cent line was called Group 1 and the others Groups 2, 3, and 4. Tables 4 and 5 are presented as an interesting procedure of comparison without conclusions.

Group B—Because of the lack of sufficient follow-up examination data the 3 cases in this group could not be studied fully. However, there was evidenced a marked improvement in the general condition and comfort of these infants, and all showed a satisfactory weight gain after they were placed on sonized Certified Milk.

Group C—Of the infants not registered and not included in the analysis of cases, telephone reports on the results of the use of the milk were received from 9 physicians concerning 12 infants. The results are as follows: satisfactory in 6, unsatisfactory in 1, and not followed up in 5. In 3 of the latter cases almost immediate discontinuance of the milk was ordered by the mother because no cream line was visible. It was impossible by reason of lack of data on all these cases for the physician to arrive at any definite clinical impressions.

Summary

It is evident from the tabulation of the condition of the infants before and after the use of sonized Certified Milk that with regard to the condition of comfort of the baby and the associated symptoms of crying, regurgitation, vomiting, abdominal distention, colic and hicough

CHART 3—SONIZED CERTIFIED MILK CURD TENSIONS*

Tension in Grams	Before Pasta- urization from Vat	After Pasta- urization from Vat	From Vent at Somo Oscillator Before Sonized	From Cooler After Bottling— After Sonized
10 and under	0	0	0	145
11-15	0	1	0	91
16-20	0	0	0	14
21-25	0	1	0	1
26-30	0	3	8	0
31-35	13	21	17	0
36-40	15	22	18	0
41-45	13	4	9	0
46 and over	13	3	3	0

* These curd tension readings were those obtained by use of the Curd Tension Meter of the Submarine Signal Company in which the operation is entirely automatic and the accuracy of the measurements is not subject to human errors as with the use of the spring balance method.

there was a marked difference in these symptoms after sonized Certified Milk was started. The findings most characteristic throughout the study are the improvement and the rapid disappearance of the above symptoms so often associated with cow's milk, especially in the young infant during the first few months of life. The rapid improvement generally noticed in the infant's comfort was one of the most prominent features of sonized milk made from Certified

0 count	0	0	10	38	12	35	37	174

CHART 2—SONIZED CERTIFIED MILK STANDARD PLATE COUNTS
After Being Sonized—Samples from Cooler and Bottler Comparative Counts Specified as Cubic Centimeter—Different Periods in Process

Date	Number of Standard Plate Counts		Average Counts		Zero Counts		Percentage Zero Counts	
	1/10	1/100	1/10	1/100	1/10	1/100	1/10	1/100
March 24-May 31, 1939 (process just started)	50	50	65	126	3	18	6	32
June 1-July 14	51	51	31	66	2	29	4	57
July 14-August 31	61	60	30	40	4	41	6	68
August 31-October 16	41	39	44	38	11	37	27	70
October 16-December 1	43	44	20	47	2	26	4 7	50
December 1-January 16, 1940 (process well established for some months)	38	38	11	8	18	35	42	92

Note. During an observation period of a little more than two weeks, April 19, 1939 to May 5, 1939, just after the study was begun, there were a number of standard plate counts which were higher than at any time in the study. These excessive counts were considered due to thermophilic organisms and evidently were in part due to some defect in processing. They are as follows

	1/10 Dilution Average	1/100 Dilution Average
Raw Certified, 4 counts	3,842	5,675
From pasteurizer, 4 counts	927	1,350
From vent on Sonic Oscillator, 4 counts	1,207	1,525
After being sonized from cooler, 17 counts	1,747	2,512

At no subsequent time in the study were counts like the above encountered

Note. The butterfat content of sonized Certified Milk has conformed with the Certified requirements of 4 per cent with the variations permitted by the Methods and Standards for the Production of Certified Milk. The average fat content of 288 samples was 3.98 per cent.

week before and after the use of sonized Certified Milk, and (3) according to the average weight gains with high and low figures in age groups. The results according to these methods are shown in Tables 2, 3, 4, and 5. These tables are not so illuminating, however, in showing the trend of the weight curve as the Infants' Percentile Weight Chart because of the number of premature and immature babies in the series. Even the latter cannot be completely adapted to this purpose but it does give a much clearer picture.

According to the Infants' Percentile Weight Chart of Cambridge Hospital, the following results were revealed in an analysis of 16 of the babies studied in whom this chart could be utilized (as the babies remained under 1 year of age during the time of the study): (1) In 3 infants the weight curve ended in a lower zone than that in which the infant's weight fell when placed on sonized milk, (2) in 7 cases the weight curve ended in the same zone as that in which the

infant's weight fell when placed on sonized milk, (3) in 3 cases the weight curve ended in a higher zone than that in which the infant's weight curve fell when placed on sonized milk, (4) in 2 cases the weight curve ended in a much higher zone than that in which the infant's weight curve fell when placed on sonized milk, and (5) in only 1 infant did the weight curve on sonized milk fall below the lower limit of the 10 per cent weight curve as shown in Fig. 1.

It is to be noted that these weight curves refer to normal, full-term babies. "Small prematurely born or otherwise exceptional babies should not be expected to conform to the pattern of this chart." In the series of 16 infants here studied, 6 were premature and 4 were immatures. The development of these infants appeared normal on this milk so far as one could judge by the clinical impressions given by the physicians.

According to the Cambridge Percentile Weight Chart and in accordance with the physical ex-

amination follow-up forms, all 16 infants who could be studied by virtue of their ages according to this method were well nourished and made satisfactory progress except 1. Of the remaining 6 infants as judged by their weight gains, progress was satisfactory in all. In 3 of the 6, detailed follow-up was carried out. In the remaining 3 there was insufficient data but the physicians summarized their opinions as satisfactory.

The stools of all infants placed on this milk were satisfactory. Constipation, if any was present before, appeared to diminish or disappear after this milk was used. In 3 cases curds and mucus were mentioned as being present in the stools prior to the use of sonized milk, and these disappeared after its use. In no instance did loose stools develop while on sonized Certified Milk in the absence of an acute infection of the upper part of the respiratory tract. In a few instances when an acute infection of the upper part of the respiratory tract occurred, some loose stools were present. These, however, disappeared quickly. It was found during the study that it was unnecessary to stop sonized Certified Milk in the presence of infections of the respiratory tract.

In recognizing the difficulty of drawing conclusions from comparison of weights, the Subcommittee using Fig. 1 was interested to see whether the cases registered (16) could be considered normal and whether the cases reported by Dr. Wolman of Philadelphia (10) remained within the grouping of the percentile lines. Arbitrarily and for the purposes of tabulation, the 10 to 25 per cent line was called Group 1 and the others Groups 2, 3, and 4. Tables 4 and 5 are presented as an interesting procedure of comparison without conclusions.

Group B—Because of the lack of sufficient follow-up examination data the 3 cases in this group could not be studied fully. However, there was evidenced a marked improvement in the general condition and comfort of these infants, and all showed a satisfactory weight gain after they were placed on sonized Certified Milk.

Group C—Of the infants not registered and not included in the analysis of cases, telephone reports on the results of the use of the milk were received from 9 physicians concerning 12 infants. The results are as follows: satisfactory in 6, unsatisfactory in 1, and not followed up in 5. In 3 of the latter cases almost immediate discontinuance of the milk was ordered by the mother because no cream line was visible. It was impossible by reason of lack of data on all these cases for the physician to arrive at any definite clinical impressions.

Summary

It is evident from the tabulation of the condition of the infants before and after the use of sonized Certified Milk that with regard to the condition of comfort of the baby and the associated symptoms of crying, regurgitation, vomiting, abdominal distention, colic and hiccough

WORKMEN'S COMPENSATION

September 18, 1941

Owing to an unfortunate experience in Philadelphia, where a laborer employed on one of the Construction Division Projects died suddenly after an injection of tetanus antitoxin (sensitivity tests allegedly not having been done) the War Department, Office of the Quartermaster General, Washington, D C, issued an order instructing all contractors and their insurance carriers and all civilian physicians to whom any contractor employees might be sent for treatment for injury sustained while at work, that tetanus antitoxin should not be administered without first making the usual tests to determine the patient's reaction to the serum. *In this order it was also recommended that all sensitive cases requiring antitoxin be hospitalized.*

It was pointed out to the War Department that among other things this recommendation might involve unnecessary hospitalization, loss of time and money, and that safety could be assured without hospitalization in every case. Under date of September 6, 1941, this order was rescinded and a new order known as Construction Division Letter No 443 was issued. It follows

"SUBJECT Instructions Concerning the Use of Tetanus Antitoxin, etc
"TO All Zone Constructing Quartermasters
All Constructing Quartermasters.

"1 This letter rescinds Construction Division Letter No 334. Effective this date you are instructed to direct all contractors and/or their insurance carriers, and through either or both of them, all civilian physicians to whom any of the contractors' employees may be sent for treatment of injuries sustained while at work, that tetanus antitoxin will not be administered to any such injured employee without first making the usual skin test to determine the patient's reaction to the serum

"2 In the event that a highly positive reaction develops and antitoxin is still necessary, the patient shall be desensitized in accordance with the circumstances indicated.

"3 The procedure in paragraphs 1 and 2 shall also be followed by all Constructing Quartermasters on Purchase and Hire Projects

"For the Quartermaster General

BRERON SOMERVELL,
Brigadier General, U S A., Assistant"

Physicians treating claimants employed on Government projects and entitled to medical care under the Workmen's Compensation Law of this state are urged to carry out the spirit and letter of this recommendation.

A careful history should be taken in every case before tetanus antitoxin is administered to determine if the patient had previously received tetanus antitoxin or horse serum injections or is otherwise allergic. Sensitivity tests should be carried out in every case by the usual and accepted procedures, which are ordinarily outlined by the manufacturers of serum in the package containing the tetanus antitoxin. Great caution should be used in desensitizing and injecting a patient found to be sensitive or suffering from allergic conditions and requiring tetanus antitoxin. Hospitalization may be provided where in the judgment of the attending physician the degree of sensitivity warrants desensitization and subsequent injection of tetanus antitoxin under hospital conditions

DAVID J KALISKI, M D, Director

THE LOUIS LIVINGSTON SEAMAN FUND

The New York Academy of Medicine announces the availability of the Louis Livingston Seaman Fund for the furtherance of research in bacteriology and sanitary science. Two thousand dollars is available for assignment in 1941. This fund has been made possible by the terms of the will of the late Dr Louis Livingston Seaman and is administered by a committee of the Academy under the following regulations

1 The committee will receive applications either from institutions or individuals up to

November 1, 1941. Communications should be addressed to Dr Wilson G Smillie, chairman of the Louis Livingston Seaman Fund, 1300 York Avenue, New York City

2 The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology or sanitary science. The expenditures may be made for (a) securing of technical help, (b) aid in publishing original work, and (c) the purchase of necessary books or apparatus

Thirty-Fifth Annual Meeting

of the

Second District Branch

PROGRAM

Thursday, October 30, 1941
Garden City Hotel, Garden City, New York

President. Burdge P. MacLean, M.D
Secretary-Treasurer Charles F. McCarty, M.D

1st Vice-President. Francis G. Riley, M.D
2nd Vice-President. John B. D. Albora, M.D

Exhibits—10 00 A.M.—5 00 P.M.

A unified County Cancer Program—Nassau County Cancer Committee, Meadowbrook Hospital, New York Memorial Hospital.

Industrial Accidents and Industrial Diseases—New York State Department of Labor

Morning Session—10 00 A.M.—12 30 P.M.

Symposium Industrial Medicine

"Pre-employment Examination"

Cassius H. Watson, M.D., medical director, American Telephone and Telegraph Company, New York City

"Occupational Diseases"

Irving Gray, M.D., chairman, Committee on Industrial Health, Medical Society of the County of Kings

"The Prevention of Infection in Injury"

S. Potter Bartley, M.D., chief, Traumatic Clinic, Long Island College Hospital, Brooklyn

"Placement of the Handicapped"

Murray Nathan, New York State Employment Service, Albany

"Rehabilitation"

Henry H. Kessler, M.D., medical di-

rector, New Jersey State Rehabilitation Clinic, Newark, New Jersey A sound film will be shown.

Afternoon Session—2 30—5 00 P.M.

"Diseases of the Thyroid Gland"

Frank H. Lahey, M.D., director, Lahey Clinic, Boston, president, American Medical Association Slide demonstration.

Woman's Auxiliary

The woman's auxiliaries of the four county medical societies on Long Island will attend the Luncheon and will hold a meeting at the Garden City Hotel in connection with the meeting of the Second District Branch. (Notice of this meeting will be mailed to the members of each of these auxiliaries.) Bridge will follow.

Luncheon—1 00—2 30 P.M.

Dr. Samuel J. Kopetzky, president of the Medical Society of the State of New York, will briefly address those present—the rest of the luncheon period will be entirely a social one. Tickets will be \$2.00 per plate.

AMERICAN CONFERENCE ON INDUSTRIAL HEALTH

The second annual meeting of the American Conference on Industrial Health will be held on November 5 and 6 at the Chicago Towers in Chicago. The conference will be attended by industrial physicians and manufacturers from all over the country. It is sponsored by the American Association of Industrial Physicians and Surgeons, which maintains a public forum for all who are interested in the prevention of disease, injury, and disability in industry and in the active supervision and promotion of health in industrial groups.

The opening session, which will be held in the morning, will consist of a symposium on the technical problems of industrial health, this will be conducted from the standpoint of the

adjustment of the working environment to the employees and vice versa. The afternoon session will consider the economics of industrial health, including the organization and cost of a health service and the value of an industrial health service to employer and employee.

The morning of the second day will be devoted to a symposium on the social implications of industrial health, including such topics as the extent of an industrial health service, the practical relation of hospital and medical care to industrial health, the part played by legislation, the evaluation of labor turnover, the lack of trained men, the experiences of management, and the interests of insurance carriers in the medical and social problems presented.

MEDICAL PROBLEMS IN THE DEFENSE PROGRAM

SAMUEL J. KOPETZKY, M D , F A C S , New York City

YOU may recall that the philosopher, Bertrand Russell, stated "Thinking is not one of the necessary activities of man. It is the product of disease, like high temperature in illness. The disease in the body politic causes certain men to think important thoughts which develop into the science of political economy."

The first fruits of these thoughts are the development of a reasonable defense mechanism for our safety. I may say, without contradiction, that in my long service within the ranks of organized medicine I have never known the medical profession more united, more cooperative, and more ready to accept the tasks so obviously ours to do as part of the program to defend our country and save our body politic from the contagious infection ravaging Europe. We are doing our part now to save the "American way of life," and we shall win that fight.

We have a potent organization and the program before us is clear. Only the superficial observer seems confused. He senses chaos and confusion because there are all sorts of plans proposed which involve medical service.

Like the circulating blood whose free flow is necessary that the body may continue to live and its parts to function properly, so in all the plans and proposals, concerned as they are with the public welfare, the medical profession is the essential factor. To a great extent the success or failure of these plans is dependent upon how well our profession will function in each one of them. To function at its best, the medical profession must see the human need involved. It must be content to work in the organized setup and it must see that the goal sought is attainable. In each of the proposals and plans, economic sacrifices on the part of the profession are essentially involved. The profession must be convinced that the goal attainable warrants this sacrificial contribution on its part. Consequently and logically, it should have a hand both in the planning and in the medical administration of each to smooth the machinery and keep its medical side functioning adequately.

We desire to cooperate enthusiastically, we desire above all to employ our every useful "yardstick" to each proposal. The quality of medical care and service delivered should never be lowered from that caliber we are wont to deliver, which has won for the American people the finest health level achieved anywhere in the world. In all the plans and proposals and in all the mechanisms of serving the public with medical care, we must maintain this level or better it.

We are organized, the organized profession has stood like a rock against the emotional critics

and embittered partisan assaults aimed at its destruction because it stood for definite principles based on considered judgments instead of on the expediencies that the given moment prompted. Let us remember that our organization does not exist for its own sake but to promote special ends and one of the principles of these is the public welfare. For this reason we survive and shall continue not only to survive but also to serve.

I have been engaged during the current year with the medical side of the Selective Service Law's administration in the New York City area. My study of the health of the age group concerned—from 21 to 35 years of age—has brought to my attention many interesting facts. I have had an actual insight into the statistics of the health of this section of our population. The average health of the group seemed to be good. The figures, based on the examination of 119,242 registrants showed that 42 per cent were inducted into the Army. Thirty per cent were qualified for limited military service, and 26 per cent were disqualified for any military service whatsoever.

No false impression should be assumed from these figures. The Army accepts only the "cream of the crop"—the healthy and the vigorous of the male population. To do otherwise would be folly. Nevertheless, from our standpoint as civilian physicians we must not be led astray by the figures themselves. To be unfit for full military service does not necessarily imply that the individual is therefore unfit to carry on a gainful civilian occupation or that he is unable to be a useful member of civilian society. A small minority are actually disabled. However, the enunciation of this latter postulate must not detract us from striving to attain a program that would result in making future generations present increasingly larger numbers of men fit for the severe exigencies of military service, using the physical standards of this type of service as the measuring rod to gauge individual health.

Realizing that although nothing could be done for many who had congenital lesions nor for others who had lesions whose pathology was known but, for the disease which this pathology signified, medical science still stood helpless and futile as far as curative therapy is concerned, nevertheless, there has been a definite effort to study the possibilities of rehabilitation among those men who, on the other hand, presented remediable conditions. Under my own direction this study of the response on the part of the public to this effort is now proceeding. Without going into detail, the results thus far seem to be promising.

This rehabilitation program has connotations far beyond the scope of the rehabilitation of those embraced within the limits of the Selective Service Law. The idea of rehabilitation is, of course, the by-product resulting from the study

President's address, meeting of the Fourth District Branch of the Medical Society of the State of New York, at the Lake Placid Club, September 26, 1941.

President, the Medical Society of the State of New York.

of statistics accumulated by the medical examination of the selectees. The percentages of disqualifications increase with each successively older age group.

With advancing age the handicap due to physical defects increases, and this has a bearing upon gainful occupation. The physically handicapped man tends eventually to become an unemployable. The group of unemployables are an ever present problem in our communities.

With these factors in mind, the Medical Society of the State of New York, should give thought to the subject. The topic divides itself into two categories: first, what to do to settle the instant problem presented by handicapped manhood so that it may be a better and healthier group? This means integrating existing facilities, hospital clinics, private practitioners of medicine and dentistry, and the existing eleemosynary lay associations organized to help the public welfare.

It must be realized that remedial therapy is but a stopgap. It puts individuals on their individual road to health. The plans to assure this are being developed without disturbing private practice and with the basic idea of bringing the ailing man into the care of his own doctor. When the case is completed, it closes an individual record. It constitutes strictly an individualized service by doctors to individuals. Of course, in the aggregate, it supplies an intense need but leaves untouched the repetition of its own features in other individuals. Therefore, the problem has deeper factors, which require our careful consideration.

If the prevention of conditions now found among our population is to be enhanced, something more than mere curative therapy must be called into action.

This implies a long-range program whose goal is a definite change in the health level of our people. This program needs much study, requires development of measures aimed at the problem as a whole, so that the statistics revealed by the physical examinations under the Selective Service Law will not become an ever recurring factor in our community life.

In a casual perusal of the factors at issue in this long-range program, there is implied a changed conception of the duties and functions of the school physician, the enlargement of his duties, and the assembly of an adequate staff of special assistants to handle special departments such as physical training, behavior problems, body growth development, tooth preservation, and health standards obtainable by comprehending the essentials of nutrition.

The long-range program has begun to evolve. Noncomprehension of its essentials, however, is not only evident in the profession itself but among the legislators and higher governmental officials concerned with public health.

In each county society I hope to see groups of physicians begin to study one or another aspect of this long-range program. I believe in the maintenance of a strong central organization because such is necessary to make essential and prompt decisions to reach a given goal. Locally, however, each program needs modification according to local needs.

In the official transactions of our Council and the various reports of our standing committees, diverse aspects of this program are beginning to

take form. Our organization exists to clarify medical situations of interest to the public, and whatever actually is good for the public we serve is good for us, too. If one reads the activities of the various programs on the national scale, what I have designated as representing fundamentals on a state scale become no different except that they are magnified by the width and breadth of our country. The wisdom of the American Medical Association in advocating a secretary of health in the cabinet is substantiated by the need of a guiding hand in the development of these programs for the public welfare. I do not mean a health officer in the sense that we have a commissioner of health in our state government. Such an officer is trained and habituated to look at the public welfare mostly from the health officer's standpoint, to better sanitation, to extend preventive measures for communities by making available proved palliatives and prophylactics within the realm of public health medicine, *per se*. Meanwhile, eleemosynary associations of private organizations like the Cancer Control Committee, the Heart Association, the Tuberculosis and Health Association, the League for the Hard of Hearing are all trying to lessen the incidence, prevalence, and recurrence of the diseases in which they are specially interested, and all this comes within the domain of nonpublic health medicine. Does it not seem that the time is ripe for our state to take the lead by establishing, as part of the state government, an officer concerned with these wider aspects of the problems of the health of the people, which task primarily should be the development of that long-range program and the coordination and integration into its very structure of all the available experience of these privately financed organizations? I would see such an officer concerned more with planning and study than with executive direction. He should also coordinate all the health activities of the state.

If the right man is chosen, it will serve as a pilot test for the questions at issue in the programs on a national scale. Sooner or later this will become a necessity, and our state government will come to it. It is germane in these times to know that we are aware of the general need. Many of our people have heretofore concerned themselves with an earnest endeavor to bring more medical care to our people. They seemed hardly concerned with the quality of medical service that they would attempt to deliver. Had they accomplished their goal, any step in real progress that might have reached the roots of the factors at issue in bettering the health of ensuing generations would have been lost for decades, because nothing would have been changed in the fundamental setup of the health control of following generations. Only the cheapest price would have been paid for individually procured medical care. The discoveries of the medical research laboratories might or might not gradually have become available to this cheapened medicine. Medical aid to the afflicted would still have been limited to the care of diseases for which cures are available. The problem of how to prevent the repetition of medical deficiencies in succeeding generations of our population would not even receive consideration because it would be outside of what is normally considered the field of public health

Under my own direction this study of the response on the part of the public to this effort is now proceeding. Without going into detail, the results thus far seem to be promising.

This rehabilitation program has connotations far beyond the scope of the rehabilitation of those embraced within the limits of the Selective Service Law. The idea of rehabilitation is, of course, the by-product resulting from the study

President's address meeting of the Fourth District Branch the Medical Society of the State of New York at the Lake Placid Club, September 26, 1941.

President the Medical Society of the State of New York.

Counties represented were Cayuga, Livingston, Monroe, Seneca, Ontario, Steuben, Wayne, and Yates.

New York County

New York City participants in the program of the Medical Society of the State of Pennsylvania, holding its ninety-first annual meeting, October 8 to 9, at Pittsburgh, included Drs. Chas. Gordon Heyd, speaking on "Common Errors in Selection of Patients for Surgery", Meredith F. Campbell, on "Urinary Obstruction in Infants and Children", and Maximilian A. Goldzieher, on "Diagnosis and Treatment of Pituitary Disorders."

The annual dinner of the New York Society for Clinical Ophthalmology was held at the Park Royal Hotel on September 15. Dr. Iago Galdston, executive secretary, Medical Information Bureau, The New York Academy of Medicine, was the guest speaker.

For the past several years the Health Department of New York City has put more emphasis upon its policy of promoting private physician examinations of children entering elementary school. Since this principle has been pursued with vigor, the percentage of those children in the new admission group examined by private physicians has increased from 14 in 1936 to 25 in 1939 and 27 for the school term, September, 1940-February, 1941.

Among the reasons for encouraging private physician's examinations are: It makes the parents appreciate the value of individualized medical attention which the family physician can best give. The family physician can make a more thorough examination and is in a position to know the child better, as well as carry out treatment. It enables school physicians to give more time to other children needing special attention.

Ontario County

Moving pictures on coramine, provided by a drug firm, were presented by Dr. Malcolm R. Blakelee as the program for the first fall meeting of the Canandaigua Medical Society on September 11. Dr. James F. Maltman, vice-president, conducted the meeting and was host for dinner at Wenna Kenna, East Lake Shore. There were 14 members present.

Pictures showed experimental and clinical results with the drug used in respiratory and cardiac conditions.

At the meeting on Oct. 9, Dr. F. C. McClellan was host, and Dr. A. W. Armstrong read a paper on "Home and Health."

Otsego County

An address by Dr. Samuel J. Kopetzky, president of the State Medical Society, was the principal feature of the thirty-fifth annual meeting of the Sixth District Branch of the state group held at the Mary Imogene Bassett Hospital in Coopers-town on September 18.

There were six speakers in addition to Dr. Kopetzky. Dr. Gilbert Dalldorf, of Pleasantville, New York, director of the division of laboratories at Grasslands Hospital, East View, New York, spoke on "The Medical Examiner and the Coroner—Is New Legislation Needed?"

Dr. Walter M. Boothby, of Rochester,

Minnesota, a professor of experimental metabolism at the Mayo Foundation and director of the laboratory for research in aviation medicine, spoke on "The Physiology of High Altitude Flying," with motion pictures.

Other speakers were Dr. Hugh Auchincloss, of New York City, Dr. Edward A. Strecker, of Philadelphia, Dr. Robert L. Levy, of New York City, and Dr. Norman H. Jolliffe, of New York City.

Putnam County

The county society, through Dr. F. C. Genovese, Committee on Public Relations, has issued the following warning, published in the county newspapers:

"With the advent of newer and almost miraculous results in the field of chemotherapy resulting from the use of such drugs as sulfanilamide and sulfathiazole in the treatment of septic or streptococcal sore throat, blood poisoning, meningitis, pneumonia, gonorrhea, and other diseases, we are apt to lose sight of the fact that in spite of their magic results on curing disease their use is not without danger.

"Because some of these toxic manifestations result fatally when improperly used, the medical profession warns the public against the use of these drugs in treating themselves. Because of ignorance the cure may be worse than the disease."

Queens County

The county society met on September 23 with the Queensboro Tuberculosis and Health Association and listened to the following program: "Recent Aspects in the Evaluation and Treatment of Pulmonary Tuberculosis," by Dr. Edgar Mayer, assistant physician at New York and Bellevue hospitals, consultant physician at Broad Street Hospital. "Surgical Therapy in Pulmonary Tuberculosis and Its Evaluation," by Dr. Louis R. Davidson, thoracic surgeon, Post-Graduate Hospital, surgeon, Queens General Hospital, director of thoracic surgery, Sea View Hospital. Scientific Exhibit—Kodachrome illustrations of the pathology of tuberculosis—8:15 P.M. Film—"Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis"—8:30 P.M.

The Friday afternoon talk on October 17 at 4:30 P.M. will be "Anemias of Childhood," by Dr. Frederick Wilke, pediatrician at St. Luke's, Babies' and Woman's hospitals.

Dr. H. V. Z. Hyde, officer-in-charge of medical work in the Second Regional Defense Area, which includes New York City, will address the open forum on defense activities which is to be held by the Queens County Medical Society Auxiliary in the Medical Society Building on Queens Boulevard, Forest Hills, October 22.

Dr. Luvia Willard, of Jamaica, chairman of the American Women's Reserve Corps, Queens Branch, will speak on allied matters.

Rensselaer County

Troy's new Medical Division of Civilian Defense met on September 12 at the Health Center to draw up plans of action in event of a bombing or other war catastrophe.

Dr. James H. Flynn, commissioner of health,

medicine—that of bringing medical care to the general population.

We should still see muscular development and muscular strength confused with inherent good health. We should still see exercise taken vicariously by thousands watching football, baseball, or hockey games instead of entering into these healthy sports themselves for their own improvement. We should still be content to see attempts on the part of government to appropriate millions to develop "little Sandows" whose eyesight and whose teeth were poor, who might have chronic discharging ears or an inherited tendency to deafness which would make them unable to hear when they reached middle age, but who could lift weights and swing dumbbells!

While great events are taking place, let us not forget our training. Each day that we serve the sick we also profit and learn something helpful for use in subsequent days. So, too, do we gain

when organized. Our particular organization has gained wisdom in handling community medical problems, it is the collective knowledge translated and tested by experience covering many years of study. We must guide our people with idealism to a brighter and better future.

Idealism has been held the offspring of suffering and hope. It reaches its maximum when a period of misfortune is nearing its visible end. At the end of a period of great economic depression among us and at the height of the suppression of freedom in Europe, with its enslavement of labor and the concomitant degradation of personal human dignity, perhaps the environmental circumstances are such that our own idealism is enhanced, and we may follow with assurance those who lead the way to a better future and healthier succeeding generations upon the American scene while we continue to live our lives in the "American way."

County News

Albany County

Albany's health defense plan initiated by a series of public meetings earlier in the year by Albany Medical College and Hospital, the Hospital Council, and the Albany County Medical Society was described before the annual convention of the American Hospital Association by E. W. Jones, director of Albany Hospital, on September 15. He added "We expect to continue our efforts during the fall and winter season, not only in presenting a second series of health talks but in providing speakers to appear before all types of organizations to discuss all phases of health improvement activities. I believe that many of you can find much of value in our 'Albany plan.'"

Chautauqua County

The Eighth District Branch meeting of the State Society was held in Jamestown on October 2.

Chenango County

Ill only a few hours, Dr. Frederick Eugene Roper, oldest practicing physician in Chenango County, died suddenly at Chenango Memorial Hospital on September 8, aged 77. He was a graduate of the Cleveland Homeopathic College and had practiced medicine for fifty-five years.

Cortland County

A joint dinner of the Cortland Bar Association and county society was held at the Cortland Country Club on September 19.

Principal speaker at the dinner was Dr. Harry S. Fish, of Sayre, Pennsylvania, surgeon of the Tioga County General Hospital in Waverly, New York.

Delaware County

Dr. George U. Carneal, of New York City, addressed the county society at its meeting on September 16 at the Elm Tree Restaurant in Delhi. A practicing surgeon in the metropolis for about twelve years, Dr. Carneal discussed "Varicose Veins and Cystic Conditions," illustrating his talk with slides and movies.

Jefferson County

Tribute was paid to the memory of the late Dr. Gilbert A. Foote, of Dexter, during the first meeting of the season of the county society, held at the Black River Valley Club on September 11.

A committee was appointed to draw up suitable resolutions on the death of the veteran physician, and the resolutions were read before the group at the meeting.

Dr. F. R. Calkins, president of the society, presided. About 45 doctors attended the meeting. Dinner was served at 6:30.

The speaker was Henry H. Kessler, Ph.D., M.D., Newark, New Jersey, whose topic was "The Rehabilitation of the Physically Handicapped." The doctor demonstrated his lecture with sound motion pictures.

Madison County

The Oneida Medical Society held a dinner meeting in Hotel Oneida on September 11 and discussed plans for the fall season.

Dr. Felix Ottaviano gave a talk on "The Paraffin Pack in the Treatment of Pulmonary Tuberculosis." The paper was based upon a four-year survey made by Dr. Ottaviano, who has specialized in tubercular cases.

Monroe County

Some 300 physicians from eight counties in central and western New York gathered September 25 for the annual meeting of the Seventh District of the State Medical Society, in Rochester.

Dr. Walter Dandy, Johns Hopkins University, was the principal speaker at the convention. He discussed brain surgery. Another speaker was Dr. Samuel Kopetzky, president of the State Medical Society and director of Medical Defense for New York State.

Recent findings of Dr. George H. Whipple, dean of the University of Rochester's Medical School, on blood substitution in case of emergency were discussed.

Other Rochester speakers were Dr. James H. Sterner, head of laboratory of industrial medicine of Eastman Kodak Company, Dr. James A. Quigley, Dr. Albert D. Kaiser, and Dr. Merle Scott.

Hospital News

Nurse-Famine Closes Floors of City Hospitals

TWO large hospitals in Queens had to close completely equipped floors in August because of the shortage of nurses. Flushing Hospital closed its sixth floor and part of the fifth, and two floors were closed at the Triboro Tuberculosis Hospital.

Growing opportunities in industry, and in public health services of one kind or another, as well as the needs of the Army Nursing Corps, are creating a shortage of nurses available for duty in hospitals all over the United States, it is indicated in a survey of the city's hospitals and other agencies. In the main, the nurses are going into other fields because they offer better wages and more attractive working conditions.

There are 400,000 nurses in the United States, according to the information bureau of the American Nurses Association, of whom 23,000 are in public health service. This field, which is growing larger every year, includes visiting nurse services, city, county, and state health departments, welfare departments, clinics, schools, and private social agencies. Each of these embraces a variety of specializations, such as orthopedics, prenatal work, pediatrics, tuberculosis, and psychiatry.

Moreover, as the nation's industry booms, increased personnel brings with it the need for expanded medical and first-aid service. Department stores, banks, and other firms are increasing their medical departments. Significantly, the number of patients able to pay for private nursing care in the home is increasing. Although this type of income is not the most lucrative and steady in the long run for the nurse, its temporary advantage—high wages—attracting many nurses from other fields.

The American Red Cross, which is the nursing auxiliary of the United States Army, assigned some 4,371 reserve nurses to active Army service during the year ended July 1. Normally, the Army has about 1,324 regular nurses.

Army nurses receive only \$70 a month, plus maintenance, but many are attracted to this service by the ranks they hold—lieutenant, captain, and so on—as well as travel opportunities and other privileges.

Among other reasons for the increasing shortage, marriage was found to be an important factor. Some nurses have married men who are able to support them without the nurses' own income, while some married nurses have retired to protect their husbands from being called up under the Selective Service Act.

Dr. Edward N. Bernecker, general medical superintendent of the New York City Department of Hospitals, reported that the department was about 300 nurses short of its normal complement of 5,797.

"They're paid better," Dr. Bernecker commented in explaining why nurses are leaving hospital service. "They get shorter and more convenient hours, and their work is not so difficult—

certainly nicer than hospital work. We're short of nurses, and it's going to be worse."

He said the shortage was primarily responsible for the department's inability to open 160 beds at Triboro Tuberculosis Hospital, Parsons Boulevard and Goethals Avenue, Jamaica, Queens. However, he added, no other hospital's services have been affected. The nursing division of the department explained that the present nurses simply have more work to do.

The department, which now conducts six nursing schools, will open a new one at Fordham Hospital.

Newsy Notes

Following a request by four of Albany's hospitals, a committee of the Board of Supervisors is studying the possibility of a publicly owned hospital in Albany County. The Albany hospitals in their request reported an increase of approximately 25 per cent in rates for welfare cases.

The matter was referred to the committee after a communication from Welfare Commissioner Leo M. Doody had been read. He said present rates paid to hospitals should be sufficient. He argued it might be more advisable to build and operate a public hospital than to pay the increases.

The four Albany hospitals said they had sustained losses totaling \$251,330 in caring for medical indigents of Albany County in 1940 and indicated that they face insolvency unless relief is afforded.

The hospital communication pointed out that because of their financial problem an increase for private and semiprivate rooms went into effect July 1. This, they said, is due to rapidly increasing labor and material costs. They asked the board to petition the State Welfare Department to permit allowances to clinic indigent cases so the county may be reimbursed partly by the state.

Skidmore College at Saratoga Springs, which since 1922 has conducted a nurses' training course through affiliation with the Mary McClellan Hospital in Cambridge, has transferred its collegiate course in nursing to the New York Post-Graduate Medical School and Hospital in New York City. This announcement was made by Dr. Henry T. Moore, president of the college, and Dr. Arthur F. Chace, president of the board of directors of the New York Hospital. A five-year course will be given by the college and hospital and will lead to the bachelor of science degree in nursing.

Bedeveled by rising commodity costs and lower yield from invested funds, St. Luke's Hospital, Amsterdam Avenue and 113th Street, ended 1940 with a net operating loss of \$604,-

was named chairman of the Division by Mayor Frank J. Hogan.

Dr. Flynn has appointed a medical advisory council to aid him in formulating medical defense plans.

Members of the council include Dr. Irving Walsh, representing the Rensselaer County Medical Society, Miss Grace Allison and Mrs. Walter Phelps Warren, representing Samaritan Hospital, Sisters Vincent and Margaret Mary, Troy Hospital, Mrs. Mary Reed, American Red Cross, Miss Catherine Tierney, representing nurses of the city, Miss Palma Ferraro, Leonard Hospital, and A. Leonard Barton, area Boy Scout commissioner.

Dr. Flynn said that it was suggested to set up first-aid stations at each hospital. Physicians and nurses of each hospital will form these units.

Provision for making beds, cots, blankets, first-aid kits, and other articles available when needed was also discussed.

Steuben County

Approximately 100 lawyers and doctors attended the annual joint luncheon-meeting of the Steuben County Bar and Medical associations at the Hornell County Club on September 11.

Guest of honor at the luncheon was Supreme Court Justice Nathan D. Lapham, of Geneva. Principal luncheon speaker was Professor Lyman

P. Wilson of Cornell University. His subject was "Doctors on the Witness Stand."

Dr. John Conway, chairman of the Steuben County Defense Council, announced the appointment of Dr. R. J. Shafer, of Corning, as chief of emergency medical services in the county. The appointment was made on a request by Governor Lehman. Dr. Shafer is director of Steuben County's laboratories and chairman of the county medical advisory committee.

Suffolk County

Dr. Vincent J. McAuliffe, of Huntington, a specialist in diseases of women, died on September 8 in the New York Hospital of heart disease after an illness of five days. He was 49 years old.

Tioga County

Dr. J. B. Schamel, of Waverly, was nominated for the presidency of the county society at the September meeting at the Jenkins Inn, Waverly.

Other officers nominated were: vice-president, Hiram Knapp, Jr., Newark Valley, secretary, treasurer, Dr. Ivan Peterson, Owego, delegate to state convention, Dr. Corbet Johnson, Spencer, alternate, Dr. F. K. Shaw, Waverly, censors, Drs. F. H. Spencer and Fred Carpenter, of Waverly, and Dr. John Jakes, of Candor. Officers will be elected at the December meeting.

BRITISH NUTRITION EXPERT GIVES THE POTATO A HAND

Advice to Britishers in wartime from Sir John Boyd Orr, expert on nutrition, leader in the League of Nations' committee on nutrition, gives the lowly potato a hand.

After milk (and Britain has enough milk to drink a fifth more) and vegetables (and Sir John says eat twice as much), the most important food produced in the tight little isles is the potato. It is a protective food, the main source of one of the vitamins. In England an average of only 4 pounds of potatoes per week per person are eaten. Some countries eat twice as much.

"Some women are afraid to eat potatoes because they think they are fattening," remarked Sir John. "This is nonsense. 1 lb of bread and butter is more fattening than 4 lbs of potatoes."

"If you think you are too fat, cut out the bread and butter and eat potatoes and vegetables. In a time of threatened food shortage, the potato is by far the most important crop, because, in addition to its special health value, it gives the highest yield of food per acre. An acre of potatoes gives twice as much food as an acre of wheat."

Application for a 50 per cent grant on a 60-bed hospital for Massena has been submitted by the town board to the Defense Public Works Office

in New York City. The hospital, including the site, would cost \$300,000, it is estimated.

POSTGRADUATE COURSES—BELLEVUE

The New York University College of Medicine announces the following postgraduate courses by the Fourth Medical Division of Bellevue Hospital.

Internal Medicine—This course is designed for physicians in general practice who wish a practical review of recent advances in diagnosis and treatment. Instruction will be given to small groups at the bedside by a member of the staff, usually the specialist in the field which is the subject of discussion. Once each week members of the course will attend the Clinicopathologic Conference.

Instruction will be given five mornings a week from 9 00 A.M. to 12 00 M. for a period of one month. Each month will constitute a complete session, beginning on the first weekday and ending on the last weekday. There will be eight sessions during the year from October through May. The fee per session is \$50.

(Note: Those who prefer to do so may attend one morning a week for a period of five months at the same fee.)

Registration will be limited for each session.

Clinical Electrocardiography—This course is planned so to teach the physician the interpretation of the electrocardiogram and its practical application that it will be useful to him in his daily practice. Under the direction of Dr. Louis F. Bishop, Jr., the members of the course will have an opportunity to learn to measure and analyze a large number of curves, to learn the operation of standard instruments, and to see patients and analyze their electrocardiograms in detail. Work is included on both the normal and abnormal electrocardiogram.

Instruction will be given Monday afternoons from 2 30 to 4 30 for a period of fifteen weeks. The first session of the year covers the period October 6, 1941, through January 12, 1942. The course will be repeated February 2 through May 11, 1942. The fee per session is \$50.

Those accepted will register at the New York University College of Medicine. Applications and inquiries should, however, be addressed to

DR. CHARLES H. NAMMACK, *Director*

Twenty-Sixth St. and E. River, New York, N. Y.

BRITISH PLASTIC SURGEON TO ADDRESS CHICAGO MEETING OF SPECIALISTS

Sir Harold Delf Gillies, one of Great Britain's leading plastic surgeons, who is now in charge of special units for the repair of facial injuries in the London area, is to be a guest of the American Academy of Ophthalmology and Otolaryngology, national organization of eye, ear, nose, and throat specialists, when it meets in Chicago at the Palmer House, October 19 to 23.

Sir Harold will address a special defense program presented by the Academy on Monday evening, October 20. The other speakers will be Dr. Irvin Abell, Louisville, Kentucky, a former president of the American Medical Association and now chairman of the Association's Committee on Medical Preparedness as well as chairman of the Health and Medical Committee of the Federal Security Agency, Col. Louis H. Bauer, Hempstead, New York, an authority on aviation medicine and now a member of the New York State Medical Society's Committee on Medical Preparedness, and Dr. Burt R. Shurly, Detroit, a former president of the Academy and chairman

of its Special Committee on National Defense. Dr. Samuel J. Kopetzky, chief of the medical division of the Selective Service System in New York City, will be the narrator for a series of motion pictures on the medical services of the Army and Navy.

Sir Harold, a native of New Zealand, is plastic surgeon to the great St. Bartholomew's Hospital in London and has been on the staffs of other hospitals at various times. At present he is consultant adviser to the ministry of health and is in charge of the three plastic surgery units in London. It was recently reported to the American Medical Association that Sir Harold's house had been bombed and that his eldest son was taken prisoner following a forced landing of his plane.

Sir Harold is an honorary member of the American College of Surgeons and of the American Dental Association. In 1935 he delivered the Mayo Lecture at Northwestern University Medical School, Chicago.

YOU MEAN HER CALF

A Jersey farmer who had put a cow and his calf in the pasture was later startled by the loud and incessant clanging of the cow bell. Investigating, he discovered that mosquitoes had devoured the cow and were ringing the bell to call the calf.—*The Chementator, New York City*

"WHAT IS THE CHIEF END OF MAN?"

"The Lord gave us two ends,
One to sit on and the other to think with.
A man's success depends upon which end he uses most.

It is a case of heads you win, or tails you lose
Take your choice"—*Quoted in Ill. Med. J.*

448 26, according to the eighty-second annual report of the institution

"Obviously, St. Luke's must either have more income for charity work or begin to curtail its services," said Lincoln Cromwell, president of the institution

In 1940 St. Luke's free service cost more than \$450,000, putting it at the head of the list of the city's voluntary hospitals in the percentage of charitable service

"At Long Island College Hospital the stork's more than frequent visits found the hospital running out of cribs in which to put the newcomers," relates the Brooklyn *Eagle*. "Did hospital officials set up an alarm about needing new equipment to cope with the added numbers of their little guests? Did they ask that new cribs be provided for what in all probability is a temporary condition, growing as it did out of last year's great increase in marriages?

"They did not. They found some orange crates, a good mechanic, hammer, nails, a saw, and some paint. The result was perfectly acceptable bassinets, fit to care for any baby of high or low degree. Time was when in anticipation of the blessed event a wash hamper was set aside for use and, with a hot iron carefully wrapped in blankets, it often served as an effective incubator.

"Using the orange crates in the present emergency is an example of ingenuity worthy of study and emulation."

The Thompson Memorial Hospital in Canandaigua is to have a new ambulance.

A new plan of student government under which nurses in training at Edward J. Meyer Memorial Hospital in Buffalo would direct their own activities in a highly democratic procedure is being considered by hospital authorities. Some of the aims of the new program are

1 To develop loyalty by developing group consciousness

2 To stimulate a larger interest in government and the welfare of the nursing school

3 To promote social development

4 To foster appreciation of the rights of individuals

A discussion club would be organized, debates conducted, democratic elections held, cabinet members appointed, and chairmen named for various activity committees

The U. S. Navy commissioned a new 400-bed hospital ship, the "Solace," August 9, 1941, at the Naval Hospital, Brooklyn. Her equipment includes six wards, two general operating rooms, an eye, ear, nose, and throat operating room, a urologic operating room, an x-ray department, a physical therapeutic department, a pharmacy, and a clinical laboratory. Through a specially constructed elevator, patients can be

removed with a minimum of disturbance from ward to ward or from ward to the operating rooms. There is ample deck space for convalescents as well as for the recreational activities of the ship's company. Meals prepared in a diet kitchen will be served to patients on compartment trays brought to their bedsides in electrically heated food carts. Each ward has its own pantry. In addition to her regular crew of 390 men and 35 officers, the "Solace" will carry thirteen medical officers, three dental officers, thirteen nurses, three pharmacists, and 139 hospital corps ratings. Captain Harold L. Jansen is the senior medical officer in charge of hospital facilities.

Improvements

A proposed Tarrytown-Dobbs Ferry Hospital, affording the most modern facilities and an ultimate 150-bed capacity, to be established in the former Luke estate on South Broadway, Tarrytown, is being studied by officials and directors of the two hospitals which would be merged.

Construction of a five-story addition to Rochester Municipal Hospital by W. P. A. awaits a conference between city and W. P. A. officials. Estimated cost of the work is \$77,378 and includes enlargement of the existing connection with Strong Memorial Hospital.

"The construction depends on whether W. P. A. can furnish the required skilled labor to go ahead with the project," Commissioner of Public Works William H. Roberts said.

The project has approval of W. P. A. in Washington, following City Council action, and now awaits only State W. P. A. check and approval for work to begin—if W. P. A. can supply the necessary labor.

An application for a grant of \$687,502 from the Federal Government for alterations and improvements to the Edward J. Meyer Memorial Hospital in Buffalo has been rejected. Mayor Thomas L. Holling was notified by Charles D. Drew, New York State projects manager. The mayor was informed that a \$50,000 allotment would be approved for urgent fire protection.

The Margaretville Hospital has a new \$2,500 x-ray machine and equipment

Overcrowding now and anticipation of a possible emergency are given as reasons for a move to seek federal funds for a \$75,000 improvement to Monticello Hospital

Madison Hospital is raising \$15,000 for a new Maternity Ward

Application for a 50 per cent grant on a 60-bed hospital for Massena has been submitted by the town board to the Defense Public Works Office

in New York City. The hospital, including the site, would cost \$300,000, it is estimated.

Counsel, Medical Society of the State of New York

Diagnosis of Fracture

AN INFANT, eighteen months of age, was brought by his mother to the office of a physician who devoted a great part of his practice to pediatrics. She told the doctor that the boy had fallen and seemed to be in pain. The child was promptly examined by fluoroscope for the purpose of ascertaining whether there were any fractures present and such examination was negative for fracture. Manual examination likewise showed no evidence of fracture. The left foot was somewhat swollen, which swelling extended to just above the ankle. The child seemed to suffer from some pain but was able to walk. The doctor bandaged the boy's ankle and instructed the mother to keep him off his feet and also suggested that x-rays be taken but the mother refused, claiming the expense would be too great. Five days later the child was brought back and an examination revealed no evidence indicative of fracture although, at that time, the child was unable to bear weight on his leg. The

bandages were renewed. The child was never thereafter seen by the doctor.

It seems that about two weeks later it was discovered at a hospital by x-rays that there was a healed fracture of the left tibia in excellent position with no bony infection.

A malpractice action was instituted on behalf of the child in which it was claimed that severe injuries resulted from the defendant's failure to diagnose a fracture. A physical examination prior to the trial revealed that the child walked entirely without a lump and that there was absolutely no deformity present after a year and a half had elapsed. The end result apparently was a perfect one.

The case was tried before an official referee and at the end of the whole case a verdict on the merits was rendered in favor of the defendant thereby exonerating him of the charges of malpractice which had been made against him.

Treatment of Xanthelasma

A YOUNG woman consulted a physician who specialized in the treatment of eye diseases, with respect to a condition of xanthelasma consisting of several patches, yellowish in character, on the lids of each eye extending from the eyelid about one inch down. She told him that nine years before the condition had been removed with electric needle, and three years later it had been removed with a knife, and two years thereafter by scissors. However, after each of said treatments, the condition had returned.

The physician undertook to treat the xanthelasma by the use of the application of chromic acid. Two such treatments were administered and after the second a slight reaction was noticed on the left eyelid consisting of a pulling down of the eyelid described as ectropion.

A malpractice action was instituted on behalf of the patient in which the plaintiff claimed that she had been disfigured owing to the negligent use of acid. On the trial of the action, before a judge and a jury, it was the contention of the plaintiff that the eyelid had been pulled down by scar tissue as a result of the defendant having improperly permitted the acid to touch healthy tissue. It was the position of the defendant that the patient had received a reaction which sometimes is unavoidable with the proper use of acid. The plaintiff failed upon the trial to introduce sufficient medical expert testimony to establish a *prima facie* case that the defendant had been guilty of malpractice in treating the plaintiff. For that reason, the case was dismissed by the court on defendant's motion.

Licensing of Foreign Physicians

A FEW weeks ago our highest State Court, the Court of Appeals, rendered a decision in an important and interesting case involving the attempt of a physician, who recently came here from another country, to become a licensed practitioner of medicine in New York.

It seems that the petitioner, M, had received a license from the government of Austria to practice medicine in 1899. He had, it seems, graduated from a gymnasium after nine years' attendance, after which he took a five-year course at the University of Vienna Medical School. From 1919 to 1933 he was head of a clinic and laboratory for postgraduate instruction in neurology and occupied the position of director

of that institution. Aside from teaching, M was the author of numerous scientific articles.

In 1938 he left Austria as a refugee and came to this country. In a few months he declared his intention to become a citizen of the United States. In 1939 he received appointment in New York as clinical professor of neurology at a medical school and research neuropathologist at a hospital. That same year he took and passed an examination in English given by the Department of Education, and endeavored to obtain the right to practice medicine by endorsement of his foreign license.

Under the provisions of the Education Law three alternatives were open to M. One of them required a licensing examination, another was to

* Matter of M v. Cole—Decided by Court of Appeals July 29, 1941.

seek endorsement of his foreign license "Upon satisfactory evidence that the requirements for the issuance of such license were substantially the equivalent of the requirements in force in this State when such license was issued, and that the applicant has been in the lawful and reputable practice of his profession for a period of not less than five years prior to his making application for such endorsement", and the third was under Section 1259 of the Education Law whereby "The Commissioner of Education may in his discretion on the approval of the Board of Regents indorse a license or diploma of a physician from another State, or country, provided the applicant has met all the preliminary and professional qualifications required for earning a license on examination in this State, has been in reputable practice for a period of ten years, and has reached a position of conceded eminence and authority in his profession."

M chose the latter course and attempted to become licensed as a person who had "reached a position of conceded eminence and authority in his profession." He filed various letters of recommendation and was accorded opportunities to be heard by the Board of Regents. The Board denied the application for endorsement of the foreign license on the grounds that M had not in their opinion reached a position of conceded eminence and authority sufficient to entitle him to the endorsement.

The Austrian physician then instituted a proceeding in the Supreme Court to obtain an order directing the Commissioner of Education and the Board of Regents to endorse his Austrian medical license. At Special Term the application was granted and the respondents appealed to the Appellate Division of the Supreme Court. The majority of that Court affirmed the ruling of Special Term but there was a dissent. The respondents carried the matter to our Court of Appeals which has now, by a five to two decision, ordered a reversal and ordered a dismissal of the proceedings.

That Court, in arriving at its conclusion, reviewed the instances in the past that Section 1259 had been invoked to permit the endorsing of licenses of persons of "eminence and authority." It was found to have only been utilized four times in the past. In the opinion, the Court said in part

"In the case at bar, after an oral hearing and after petitioner's application had been before them for consideration upon three separate occasions, appellants have come to the determination that the eminence of this applicant does not satisfy the standard required by the statute as it has been interpreted by them in the past. It is this determination which we are asked to declare to be arbitrary, unfair and capricious upon this record. It is our opinion that such is not the case.

"It is not claimed here by the petitioner nor does the record show that this petitioner is responsible for any outstanding original contribution to any field of medicine. Thus, if the eminence of petitioner is in any way to satisfy the high degree of eminence which has been set as a prerequisite for the indorsement of a medical license, it must be shown that his eminence in the field of neurology is so great that it can be said to be arbitrary, unfair or

capricious for appellants to have refused to make an exception to the general standard in his case.

"A careful examination of the record in the case at bar reveals that such is not the case. The record shows that petitioner has an enviable record as the Director of the Neurological Institute at the University of Vienna from 1919 to 1933, that he was in active practice in Vienna from 1905 to 1933, and that he has published about two hundred scientific papers and books written in his native German tongue as well as being accorded membership in the American Neurological Society. Upon his enforced emigration to America, Dr M has continued his career and has received an appointment as a Clinical Professor of Neurology at A and as Research Neuropathologist at the B Hospital. The letters from his friends, former students, and associates in the field of neurology clearly show that he has attained their esteem and respect as a medical teacher and practitioner. This evidence, while it is impressive, does not sustain the contention that appellants must make an exception to their general standard in Dr M's case because their refusal to be satisfied that he ranks among the few outstanding men in his profession as evidenced by universal recognition and outstanding appointments to positions of high responsibility in this State is arbitrary, unfair or capricious.

In the case at bar neither were appellants satisfied that the evidence of his eminence in his profession introduced by Dr M proved that they should make an exception to their general standard in his case, nor was this evidence so overwhelming that we can say as a matter of law that their refusal to make such an exception was arbitrary, unfair or capricious. It follows that in the case at bar the refusal by appellants to indorse petitioner's medical license was not an abuse of their discretion. Since the Board of Regents has determined that Dr M has not shown that he is of equal eminence with any of the other four persons who have been licensed pursuant to this Section, that determination is binding upon us.

"Petitioner does not allege, nor is there any evidence to support a claim, that the standard which has been adopted by appellants is arbitrary or unreasonable. The law is well settled that it is not always necessary that license legislation prescribe a specific rule of action. Where it is difficult or impractical for the Legislature to lay down a definite, comprehensive rule, a reasonable amount of discretion may be delegated to the administrative officials. Where the administrative agency has adopted a standard as an interpretation of the broad powers granted to it by the statute, we may declare such a standard invalid only in the event that it is so lacking in reason for its promulgation that it is essentially arbitrary.

"In view of the liberality accorded by New York State to practitioners of other States pursuant to Sections 51 and 1256 of the Education Law, as well as the numerous applications made by noncitizens to practice medicine in New York, the interpretation of the powers confided to them by the Legislature through

the provisions of Section 1259 is not unreasonable. Thus in the case at bar, where the Board of Regent has interpreted the words 'conceded eminence and authority in his profession' to mean an outstanding original contribution to a certain field of medicine or standing among

the first few men of his profession as evidenced by universal recognition and outstanding appointments to positions of high responsibility in the State, such interpretation cannot be said as a matter of law to be unreasonable or arbitrary."

HOSPITALS AND NURSES AIDING BRITISH COLLEAGUES

Physicians and nurses of the United States have quietly stepped into war relief work giving benefits, contributing money, offering their time and help in many ways, a report, recently made by Mrs Coda Martin of The British War Relief Society, discloses. Mrs Martin is director of the Society's Medical Aid Department with headquarters at 730 Fifth Avenue, New York City.

Although most of the activities to date have been in New York City and vicinity, plans are now under way to launch a nation-wide drive among hospitals, doctors, and nurses for funds to purchase supplies and equipment for 800 voluntary British hospitals. Many benefits are now being arranged for the fall and winter seasons.

A large proportion of the money collected to date has been raised through the Greater New York Hospital Association, which in December, 1940, voted to give complete cooperation and assistance to the B W R S through the Medical Aid Department by raising funds in its 100 member hospitals. A goal of \$50,000 was set.

James U Norris, now president of the Greater New York Hospital Association, was appointed chairman of a special committee to organize the personnel of the hospitals but in September, 1941, Miss Mabel Davies, superintendent of Beekman Hospital, was appointed the new chairman. Serving on this committee are the following people: Dr Claude W Munger, director, St Luke's Hospital, Mr John F McCormack, superintendent, Presbyterian Hospital, Dr W B Talbot, superintendent, Post-Graduate Hospital, Mr Wm. B Seltzer, superintendent, Bronx Hospital, Dr E M Bluestone, director, Montefiore Hospital, Rev John

J Bingham, superintendent, New York Catholic Charities, Rev C O Pederson, superintendent, Norwegian-Lutheran Deaconesses' Home and Hospital, Brooklyn, Mr Boris Fingerhood, superintendent, Israel Zion Hospital, Brooklyn, Mr John H. Olsen, superintendent, Richmond Memorial Hospital, Staten Island, Miss Mabel R. Davies, superintendent, Beekman Hospital, Dr Joseph Turner, director, Mt Sinai Hospital, Miss Isabel Byrne, superintendent of nurses at Roosevelt Hospital and president of the Thirteenth District Nursing Group, New York City.

To date, 16 of these hospitals have given benefits and raised a total of approximately \$9,000 at a cost of less than 1 per cent. Others have scheduled benefits and parties for the early fall.

Mrs Martin expressed the hope in her report that this winter voluntary hospitals in other cities all over the United States will also organize to give benefits and that the drive will become a national campaign.

A number of nurses' homes and individual nurses in Greater New York have given benefits and contributions independent of the efforts of the voluntary hospitals. These contributions total more than \$5,000.

A campaign has been conducted by the Physicians' Committee of Greater New York, which was formed in April, 1941, by Mrs Martin, director of the B W R S Medical Aid Department. Many doctors have given outright contributions, and others have pledged certain sums each month for the duration of the war.

A similar committee for all members of the dental profession of Greater New York is now being organized.

JOINT STATEMENT

U S CIVILIAN DEFENSE AND AMERICAN RED CROSS

According to the joint statement issued by the U S Director of Civilian Defense and the Chairman of the American National Red Cross, the state and local defense councils are the official agencies responsible for the coordination of all available resources that may be required for civilian protection in the event of belligerent action.

Defense councils should, therefore, acquaint themselves with the resources of the local Red Cross chapters in providing food, clothing, shelter, nursing care, transportation, and other basic necessities and should integrate them into the comprehensive local program.

Duplication of trained and experienced personnel and of available supplies of the Red Cross should be avoided except where supplementation

is essential to meet the anticipated needs of the community.

September 18, 1941

GEORGE BAHR, M D
Chief Medical Officer
Office of Civilian Defense

In cooperation with the American National Red Cross, the New York State Health Preparedness Commission is completing a survey of the current facilities and activities of the individual Red Cross chapters in New York State. This information will be placed in the hands of the chairmen of the defense councils and the chairmen of the county health preparedness committees to assist them in planning full utilization of the Red Cross facilities in the development of the Civilian Defense Program in their communities.

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Albany On September 24 a membership tea and a combined business meeting was held.

Cattaraugus On August 5, 1941, about 35 guests assembled at the Olean House, Olean. Mrs. Carlton E. Wertz, guest speaker, and Mrs. Walter Rennie, both of Buffalo, were present, and a luncheon was served in the Colonial Room of the hotel. The following officers were elected: Mrs. E. C. Moore, Olean, President, Mrs. A. L. Remals, Olean, first vice-president, Mrs. R. L. Tschoff, Gowanda, second vice-president, Mrs. R. F. Garvey, Olean, recording secretary, Mrs. D. J. Maloney, Olean, corresponding secretary, and Mrs. C. A. Greenleaf, Olean, treasurer. On September 8, 1941, a board meeting was held at Olean, and the following committees were named: membership—Mrs. H. G. Storer, program—Mrs. M. G. Sheldon, public health and public relations—Mrs. J. P. Kane, economic—Mrs. A. J. Lorenzo, home and hospitality—Mrs. W. C. Goodlett, press and publicity—Mrs. L. D. Gunn, historian—Mrs. R. C. Peale, and telephone—Mrs. N. P. Johnson. Meetings are to be held the first Monday in October, December, February, and April. On October 6, 1941, a general meeting was held at the Evergreen Tea Room at Great Valley.

beauty and romance of this distant country but giving a clear and interesting résumé of the medical care and hospital facilities in India. At this meeting the members discussed the advisability of meeting every month instead of the six meetings held last year. Everyone was in favor of this change. A motion was made that the Bylaws be revised and that we meet every month, the alternate month to have no guest speaker but to serve as a sewing or knitting bee for the British War Relief. It was also unanimously decided to continue our help with the Summer Camp at Pine Crest Sanatorium—a project that included all of Herkimer County insofar that privileged children were given the advantage of a summer camp with trained counselors, balanced diets, and the chance to improve not only physically but mentally and socially as well. We have decided to make this our pet activity. This year we held a county-wide card party and raised \$70, with which a slide was purchased for the playground. We feel that these meetings will bring us closer together, that we will enjoy the contacts we make and will be more closely united not only as an auxiliary to the Medical Society but as friends.

Convention Notice The Convention is to be held at the Waldorf-Astoria, New York City, from April 27 to 30. The Convention Chairman of the State Medical Society is Dr. J. L. Bauer, 984 Bushwick Avenue, Brooklyn. Let us all mark these in our datebook.

Did you read "A Personal Inventory" in the spring *Bulletin*? If you did, let us read it again. "When we join the Auxiliary, do we think 'How much is there in it for me?' or rather 'How much can I do through this organization to promote good health and right feeling toward medicine in my community?' and 'How much service can I render?' Silence may have been golden in the days gone by, but in these chaotic times action may be worth its weight in platinum. A person may be intelligent but, if he simply hides his light under a bushel, he is no different than any other clod. As a part of a great whole, the wives of these fine medical men in this country, we must put aside petty jealousies and pet ideas and work for the accomplishments that will benefit all in the end. One officer must continue on with the work of the predecessor, provided it is a step forward. Living today and serving through the Auxiliary, are we making our communities better than each citizen of this grand Democracy may have a finer, healthier, happier place in which to live? We build on the past for the future. Take stock of our resources, material and human, and then create in others the will to use what we shall pass on to them. We must work diligently, yet unconspicuously, remembering always that we are just the auxiliary or the aid to the medical profession."

Erne The auxiliary began its active fall season with the first executive board meeting on September 10, in the board rooms. A business meeting was held with a full quota of members present. The big project before Erne County was the Eighth District Branch Meeting at Jamestown on October 2. The newly formed Chautauqua Auxiliary acted as hostess this day. A special luncheon was given with the doctors and their wives together in joint meeting. Mrs. George Adams, our own president, was present with a welcome to all Auxiliary members.

Fulton A business meeting was held at the home of Mrs. J. Edward Grant, of Northville, and activities for the fall and winter were discussed. A report on the card party at the Adirondack Inn, Sacandaga, in July by the Auxiliary for Bundles for Britain netted the unit \$114. This will be divided equally between the Gloversville and Johnstown branches of the organization. The auxiliary has made it possible for one underprivileged child to spend one week at the Fulton County Children's Camp this summer. Refreshments and a social time followed the business meeting.

Herkimer The first fall meeting of the auxiliary was held at Mrs. Smith's Corner House in Herkimer, with Mrs. Horace Morey presiding. Twenty members were present. The guest speaker was Mrs. Marcus DeWolfe who spoke to the members on India. Mrs. DeWolfe lived there several years and her talk was both fascinating and instructive, touching not only on the

REVIEWED

Infantile Paralysis Edited by W L Colze
Volume A40 of the *International Bulletin for Economics, Medical Research, and Public Hygiene* Octavo of 179 pages, illustrated New York, National Foundation for Infantile Paralysis, Inc., 1939-1940 Paper

This small volume contains the latest developments in research, prophylaxis, and methods of treatment of infantile paralysis. It is sponsored by the International Foundation for Infantile Paralysis.

Eminent authorities such as Drs Josephine B Neal, W Lloyd Aycock, James D Trask, Albert B Sabin, John A Toomey, and authors from European countries have contributed short, terse, instructive articles making this report one that should be in the hands of every physician in order that he may have the most up-to-date scientific evaluation of the problem of infantile paralysis.

The individual articles have been well chosen, and the authors are qualified to speak with authority in the field they represent. One cannot praise too highly a volume of this nature.

JOSEPH L ABRAMSON

The Doctor Takes a Holiday An Autobiographical Fragment By Mary McKibbin-Harper, M D Octavo of 349 pages, illustrated Cedar Rapids, Iowa, The Torch Press, 1941 Cloth, \$2.50

Dr McKibbin-Harper, editor of *Women in Medicine*, official publication of American Medical Women, among many other trips made a two-year tour of the world. This was something of a busman's vacation. We visit with the doctor, therefore, most of the outstanding points of interest but are brought into close contact with many of the local medical problems and conditions. Because of her official position and special interest, the author has emphasized, and rightly so, the fine work done by the many women practicing medicine throughout the world. One reads on page 182 of "two hundred women's hospitals in India staffed entirely by women, as well as women's wards in various hospitals over India under the care of women doctors." The chapters dealing with the Holy Lands, India, and China are particularly interesting and instructive. Dr McKibbin-Harper has an open mind and a seeing eye.

JOSEPH RAPHAEL

Emergency Surgery By Hamilton Bailey, F R C S Fourth edition Octavo of 944 pages, illustrated Baltimore, William Wood & Company, 1940 Cloth, \$15

Doctor Bailey's fourth edition on *Emergency Surgery* has provided the reviewer with many hours of interest and admiration on the excellent manner in which the work has been presented.

There is reference to practically every subject that might be of interest and aid to the surgeon. Included are both the simple and more difficult

procedures presented in a concise manner which, together with 930 illustrations including many in natural color, have made this volume one of the most interesting and complete ever published.

RALPH F HARLOE

Diagnostic Procedures and Reagents. Techniques for the Laboratory Diagnosis and Control of the Communicable Diseases. First edition. Octavo of 353 pages, illustrated New York, American Public Health Association, 1941 Cloth, \$2.75

This book, compiled by experts for the American Public Health Association, makes a valuable addition to the list of laboratory manuals. The material is presented clearly and concisely and in a manner easy to understand. Although the scope of the work is limited to communicable diseases, there is much information applicable to the diagnosis of other diseases of infectious nature. The book deserves, and almost certainly will receive, a warm welcome by workers in public health and hospital laboratories.

ALVIN HOLLANDER

Mental Disease and Social Welfare By Horatio M Pollock Quarto of 237 pages, illustrated Utica, State Hospitals Press, 1941 Cloth, \$2.00

This timely publication, dedicated to Dr William J Tiffany, New York State Commissioner of Mental Hygiene, brings into one volume a number of outstanding studies, largely of a statistical and sociologic nature, already published by the author. Dr Pollock is uniquely qualified to write authoritatively upon these phases of preventive psychiatry, psychopathologic studies, and sociologic trends, having served the New York State Hospital Commission as statistician and editor since 1911.

The contents include chapters on the social significance, expectation, and outcome of mental diseases in the United States, economic loss and the effects of the economic depression in relation to mental disease, trends in outcome of general paresis, recurrence of attacks in manic-depressive psychoses, hereditary and environmental factors in the causation of manic-depressive psychoses and dementia praecox, mental disease in relation to environment, sex, and age, the future of mental disease, what happens to patients during first year of hospital life, statistical study of patients treated with metrazol, mental disease in Peru, use and effect of alcohol, thirty years of alcoholic mental disease in New York State, and, finally, is the paroled patient a menace to the community? Each chapter comprises a complete study. A comprehensive bibliography is appended. Numerous tables and graphs strikingly emphasize the content.

No worker in social welfare, psychiatry, mental hygiene, sociology, public health, and related fields can afford to be without this most valuable

**HEMATINIC
PLASTULES***

● Hematinic Plastules provide ferrous iron in small soluble elastic capsules—a modern, convenient dosage form. Where iron therapy is indicated, Hematinic Plastules can usually be relied upon to bring about a steady, rapid rise in hemoglobin. Their administration is seldom complicated by gastric disturbance.

Hematinic Plastules are an economical iron preparation especially effective for the treatment of the iron deficiency anemia of pregnancy, for chronic blood loss, or post-infection anemia.

Hematinic Plastules are available in two types, Plain or with Liver Concentrate, in bottles of 50 and 100.

A New Course in Education

A new educational field suggested by Morton D. Kintusch, Director of the Albany Vacation Service, is arousing wide-spread interest in the travel industry and in Government circles.

A reply to the suggestion that colleges offer courses that would prepare graduates for specialized work, in travel, was made by the Supervisor of the Department of Interior, National Park Service, United States Travel Bureau. It stated that the idea expressed concerning the need for various college courses devoted to training men and women for the growing field of travel promotion strikes a very responsive chord. The Government has long entertained thoughts along a similar line.

The Supervisor, J. L. Bossemeyer, intimated that the Government's department travel publication would devote pages to advancing the idea. In general, the pos-

sibilities for studies for a "travel career" would cover courses in subjects such as public relations, travel sales methods, travel geography, foreign exchange, accounting, hotel, steamship, bus and airplane travel, travel clubs, literature, etc.

Opportunities for the graduates of such training would be sufficiently great to make this specialized schooling worth while for many youngsters who now view with dismay the overcrowded professional fields today. In addition few professions, if any, could be more interesting.

As family counsellors, as well as heads of families, this new educational prospect should be of interest to physicians. It may possibly open new avenues of suggestions for starting many youngsters on a good, healthy and happy career.

contribution. It elucidates and points the way to a melioristic resolution of very real and knotty social problems which demand more public recognition, understanding, and financial support for study, prevention, and treatment
FREDERICK L. PATRY

Approved Laboratory Technic. Clinical Pathological, Bacteriological, Mycological, Parasitological, Serological, Biochemical, and Histological. By John A. Kolmer, M.D., and Fred Boerner, V.M.D. Third edition. Quarto of 921 pages, illustrated. New York, D. Appleton-Century Company, 1941. Cloth, \$8.00.

The third edition of this book is recommended to the attention of laboratory workers and practitioners of medicine who either do their own laboratory work or desire to keep abreast of the new methods in this field.

The book combines all the excellent features of the second edition and includes besides, in the form of an appendix, the newer laboratory procedures that have warranted general clinical use. Such tests include Quick's method of determination of prothrombin, as well as the estimation of liver function by the hippuric acid test and a method for the determination of thiocyanates in the blood, among others.

This book has received the approval of the American Society of Clinical Pathologists as one of standard methods and should continue to enjoy the popularity that it has had in the past.
THEO J. CURRHEY

A Textbook of Clinical Neurology. By J. M. Nielsen, M.D. Quarto of 672 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$6.50.

This volume is an effort to present a simplified "text of the subject during the time allotted to neurology in a general medical course" and "to form a systematized groundwork in clinical neurology." In this aim it succeeds only partially. The subject matter is well organized but irregularly treated. Undue emphasis is given to some subjects and too little to others. The usual preliminary treatment of neuroanatomy and physiology has, with good sense, been eliminated. At the same time the subject matter reflects much personal experience with the result that it is often refreshing and holds interest. The style is conversational and avoids the cut-and-dried style of the formal textbook. This refreshing discursiveness would make for greater appeal and usefulness to the student and general practitioner were it not for the errors that have crept into the text and, it is hoped, will be deleted from future editions. Numerous brief vignettes of special experience are interspersed through the book. They are often disconcerting and occasionally confusing and, from brevity, throw little light on the problems. Many of them could well have been eliminated. The general practitioner and internist will find the book generally pleasant and useful reading. The neurologist will find it meager for reference. The volume is up to date. Treatment is stressed throughout.

The book is handsomely bound and is a credit to the excellent reputation of the publisher. The type is unusually clear and readable. The illus-

trations are excellent, well chosen, appropriate and well reproduced.

I. S. FREIMAN

A Method of Anatomy Descriptive and Deductive. By J. C. Boileau Grant, M.D. Second edition. Quarto of 794 pages, illustrated. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$8.00.

This second edition is essentially the same as the first, with the exception that several additional chapters have been added relating to topics not discussed previously. These additional chapters deal with general descriptions of the body systems, with some more detailed discussions of certain of the skeletal construction. There are approximately 140 more pages.

In addition to the line drawings in the first edition, there are some more detailed reproductions included in this edition. In general, this book is a somewhat elaborated first edition. It is not an anatomic reference book but offers an approach to the study of anatomy which makes this subject interesting and more comprehensible than does the average textbook.

WALTER H. SCHMITT

Medical Diagnosis and Symptomatology. By Samuel A. Loewenberg, M.D. Fifth edition. Quarto of 1,139 pages, illustrated. Philadelphia, F. A. Davis Company, 1941. Cloth, \$12.

The book is well arranged and written in a simple style. Short, inclusive paragraphs summarize important features. New chapters including endocrinology, diseases of the blood-making organs, diseases of the cardiovascular system, and the discussion on vitamins and vitamin deficiency diseases constitute an important addition to this revision. The section on laboratory procedures is adequate for the routine office procedures. The book is adequately illustrated with photographic and anatomic reproductions. It serves its purpose as an aid and a guide to the examining physician. The section on physical diagnosis can be of value not only to the physician but to the student as well. This book should become part of the library of every practicing physician.

IRVING GREENFIELD

Accidental Injuries. The Medico-Legal Aspects of Workmen's Compensation and Public Liability. By Henry H. Kessler, M.D. Second edition. Octavo of 803 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$10.

This revised edition contains much information that is of importance to every physician who practices industrial medicine. It is concerned with the physician's responsibilities in the interpretation of medicolegal problems. The differentiation between occupational disease and occupational accident is clearly made. The chapters on traumatic neuroses and rehabilitation have been rewritten. Much careful attention has been given to the latter. There is a short discussion of the medicolegal aspects of the various types of industrial diseases and industrial accidents. Every physician on the industrial panel should be familiar with the contents of this valuable contribution.

"Getting Our Minds Off Our Troubles"

During the trying period of this emergency, it is essential that the American people be kept reminded that there is a need to continue normal habits of recreation and travel. So says the United States Travel Bureau.

Faced as we are with an extremely serious situation, the nerves and morale of the people will not be improved by a continuous grim and unrelentless attention to the problems and troubles that confront the nation as a whole. It is necessary, states the Government travel department, to "get our minds off our troubles" at intervals, and the prescription suggested is healthful rest or exercise in the out-of-doors, or by refreshing change of scene that comes through travel.

A secondary reason for maintaining these recreational and travel activities is for the important contribution that they make to the Nation's economic welfare. During the current year, according to conservative estimates, we will spend nearly seven billion dollars on travel in the United States. This is an important source of revenue for many types of business, and it is particularly valuable as a means of spreading to remote parts of the country a little of the prosperity that is now apparent in metropolitan areas but not likely to be felt otherwise in these places.

These thoughts have been emphasized constantly by the Chief of the United States Travel Bureau, Mr W Bruce Macnamee. The Bureau's slogan for 1941—"Travel Strengthens America"—has been widely used throughout the country

In spite of the fact, however, that the United States Travel Bureau is the Federal Government's official travel organization, it is not at present, a defense agency. Yet, those interested in maintaining travel and recreation through the emergency had been hoping for a statement from one of the key defense officials that would indicate that these officials hold the same views regarding the need for maintaining travel that the Government's bureau holds. The longed-for statement was made last month by Federal Security Administrator Paul V McNutt, who also holds the post of Defense Recreation Coordinator. In a signed article in the August issue of the *Official Bulletin* of the United States Travel Bureau, he said, in part

"When the national defense program was initiated the President and the Nation as a whole recognized that safeguarding the Nation is not wholly a matter of guns, bombers, tanks and warships. In fact, the most significant aspect of our defense efforts may well prove to be the fact that the national state of health, welfare and recreation, as integral parts of the defense program, has been accepted with prompt unanimity. Travel, a paramount factor in recreational activity, is important to national health which is vital to our manpower, defense production and morale. Therefore, the maintenance of travel facilities is doubly urgent at this time.

"The pleasure and relaxation of travel will do a great deal toward bringing about a national unity which is essential to our defense program. Furthermore, we are

A Handbook for Dissectors By J C Boileau Grant, and H A Cates Duodecimo of 239 pages Baltimore, Williams & Wilkins Company, 1940 Cloth, \$2 50

This dissecting manual is intended to be used in conjunction with Grant's *Method of Anatomy*. It is clearly and concisely written and describes dissection approaches to certain parts of the body which are somewhat of a departure from the methods ordinarily used

WALTER H SCHMITT

A Manual of Allergy for General Practitioners By Milton B Cohen, M D Duodecimo of 156 pages New York, Paul B Hoeber, Inc., 1941 Cloth, \$2 00

This small-sized book deals in a practical and simple manner with the broader aspects of allergy and with many of the allergic diseases. It has been written primarily for the general practitioner as an introductory guide prior to his reading of the monographs and textbooks on the subject. The author presents only his own point of view and avoids discussion of the literature and controversial questions.

In addition to chapters on diagnosis, treatment of hay fever, asthma, etc., one finds excellent material on the "life history of an allergic patient" and a good discussion of the changes in growth and development of allergic children. A review of important allergens that may be encountered is included. Urticaria, angioneurotic edema, gastrointestinal allergy, and migraine are only briefly mentioned.

MAX HARTEN

The Medical Aspect of Boxing By Ernst Jokl, M D Octavo of 251 pages, illustrated Johannesburg, South Africa, the Author, Witwatersrand Technical College, Eloff Street, 1941 Cloth

The author has gathered together and analyzed clinical and research evidence demonstrating the dangerous effects of blows received during boxing on the nervous system and also in a lesser degree on the heart.

Delayed sequelae of various types of "knock-out" are also analyzed. Careful researches of reported cases in the literature and the addition of many personal experiences of the writer yield a large number of severe injuries ranging from paralysis of the serratus anterior and quadriceps muscles through permanent injury to the facial nerves, rupture of the pectoralis major, arteriovenous aneurysm, hemothorax, fractures of the mandible, concussion of the brain and lung, and an exceedingly impressive number of fatalities from blows in the ring.

Regarding its value as an exercise, he points out that any benefits coming from boxing can be equally well achieved through other sports that do not constantly endanger health and the efficiency of the central nervous system.

The author presents considerable evidence of the brutalizing influence of this sport not only upon the boxers themselves but upon the spectators. He makes a strong plea for the abolition of boxing among members of the air corps claiming that delayed results of intracranial injuries sustained during boxing have produced many

fatal accidents during subsequent flights. In all, through the tremendous amount of material he has gathered together and comprehensively presented, the reader is given the impression that boxing is anything but a "manly art of self-defense," that as a sport it is markedly inferior to many others, that it has inherent in it many dangers that other sports lack, that it is brutalizing for participant and spectator alike, and that it is an undesirable form of physical education.

HARRY KOSTER

Oral Pathology A Histological, Roentgenological, and Clinical Study of the Diseases of the Teeth, Jaws, and Mouth By Kurt H Thoma, D M D Quarto of 1,306 pages, illustrated St Louis, C V Mosby Company, 1941 Cloth, \$15

An adequate review of this well-illustrated book of 1,306 pages in the available space is impossible not alone because of size but also because of the comprehensive scope of the text. It ably covers the fields of heredity and endocrinology in relation to the oral cavity, modifications and maldevelopments of the face and jaws, injuries and diseases of the teeth, of the periodontal membrane of the jaws and soft tissues, and of the salivary and mucous glands, and all types of tumors. However, particular emphasis might be placed upon its value to dentists and physicians alike both as an office reference volume and for the thoughtful study and correlation of the joint problems of both professions. In this connection the recent action of the Association of Deans of Medical Schools in assuming direction, at least in part, of the education of the intern has given impetus to the correlation and cooperation of the specialties of medicine. Their requests for more clinicopathologic conferences, as a specific example, have made necessary increased library facilities in the modern hospitals. At present there is a woeful lack of knowledge, cooperation, and coordination of dental information as related to the other specialties of medicine. This book in the hospital library and frequently used in the pathologic conferences would go far to correct this deficiency.

JOSEPH J STAHL

Techniques of Conception Control By Robert L Dickinson, M D, and Woodbridge E Morris, M D Quarto of 56 pages, illustrated Baltimore, Williams & Wilkins Company, 1941 Cloth, \$0 50

Whether the physician believes in the control of conception or not is beside the point, since it is certain that a large proportion of the public do. Therefore, the physician should be equipped to give advice and offer technics for control of conception or be in a position to refer such patients to reliable individuals or institutions for advice. In either instance it behooves the modern physician to be "up" on his knowledge of family planning.

This brochure by Dickinson and Morris does just this and does it unusually well. The illustrations are second to none, and the publishers are to be congratulated for their well-nigh perfect reproduction of them. We can, without reser-

committed to the sound policy that leisure must com-
plement labor. That commitment entails an obligation
to see that hours off duty can also be well spent.

"More than half of the population of the United States
—over 60 million people—travel for pleasure and re-
creation each year. The national emergency which has
been accompanied by increased wage scales and overtime
pay, has accelerated their travel pursuits. In a vast wave
they spread over the Nation, and they come in contact
with new people, new conditions, new scenes which per-
manently influence their thinking and their activities on
social and economic problems affecting the people as a
whole. They spend large sums of money each year.
In 1940, their total expenditure was over \$6,000,000,000.
That money provides funds for defense purposes.

"Summing up, their visits and their expenditures in-
turn profoundly effect the areas to which and through
which they travel. Thus, national unity is engendered.

"Travel—the common activity of a majority of the
people—is one of the major sources from which the Na-
tion obtains much of its strength and creativeness."

This is a significant statement by a man empowered
by the President to coordinate the Nation's health, wel-
fare and recreation during the emergency and it is im-
portant to every one dealing with travel. Here we may
include the medical profession, too, for travel is still
prescribed for many persons in ill health.

Perhaps many have hesitated to plan any extensive
traveling during 1942—for such the reassuring remarks
made by Mr. McNutt may prove beneficial. There is
little prospect that there will be any curtailment of
travel during the coming months. If anything, it
should increase greatly with thousands of families prob-
ably planning now to spend vacations on trips to see
their boys in the various camps throughout the country.

HARVEY B MATTHEWS

A History of Medicine By Arturo Castiglioni, M.D. Translated from the Italian and edited by E B Krumbhaar, M.D. Octavo of 1,013 pages, illustrated New York, Alfred A Knopf, 1941 Cloth, \$8 50

The first edition of this excellent work was published at Milan in 1927, a French translation of the book appeared in Paris in 1931, and now we are presented with an English version. The present edition represents virtually a new work, having been amplified and brought up to date by Professor Castiglioni and Dr E B Krumbhaar, who translated and edited the book. The book is extremely well printed, serviceably bound in handsome blue cloth, and illustrated with 443 extremely well-chosen pictures.

The text of the book is no less excellent than the dress in which it appears. Castiglioni's *History of Medicine* is at present the best single-volume history of medicine available in the English language. As the author of some twelve volumes on the history of medicine and as a frequent contributor to the journals devoted to medical history, Professor Castiglioni's qualifications for writing such a history of medicine are unquestionably excellent. Although the book is exceedingly exhaustive, the author's happy felicity of style makes it a work that can be read continuously from cover to cover.

The scope of the book may be gathered from the titles of some of its twenty chapters: Medical Thought in Its Historical Evolution, The Origin of Medicine in Prehistory and in Primitive Peoples, Mesopotamian Medicine, Magic and Priestly Medicine, Old Egyptian Medicine, Priestly Medicine, Origins of the Philosophic Concept, The Medicine of the People of Israel, Theurgic Medicine, Canonical Codifications of Sanitary Laws, The Medicine of Ancient Persia and India, Far Eastern Medicine, The Medicine of Ancient Greece, The Golden Age of Greek Medicine, Roman Medicine, The Decadence of Medical Science, Arabian Medicine, Medicine in the Later Middle Ages, The Renaissance, The Seventeenth Century, The Eighteenth Century, The Nineteenth Century, and The Twentieth Century.

The book is supplied with a very good bibliography of 44 pages, an index of names, an index of subjects, and a table illustrating the rise of medical faculties. As a work that may be read with pleasure and also used with equal facility as a book of reference, it is highly recommended.

GEORGE ROSEN

Arthritis and Allied Conditions. By Bernard I Comroe, M.D. Second edition. Octavo of 878 pages, illustrated Philadelphia, Lea & Febiger, 1941 Cloth, \$9 00

This second edition of Dr Comroe's work on arthritis, appearing as it does so soon after the first edition, attests to its reception by the medical profession. The book has been largely rewritten but the general plan is unchanged. It is larger by more than 100 pages. The completeness almost disturbs one, as even the prevailing hotel and treatment prices at the various

spas are given. If it were not for the wonderful analysis and therapy of the text, it might suggest a Baedeker on arthritis. This book should be of value to every physician.

JAQUES C RUSHMORE

Chemical Warfare By Curt Wachtel. Octavo of 312 pages. Brooklyn, Chemical Publishing Company, 1941 Cloth, \$4 00

The author is an internationally known chemist on industrial chemical poisons and chemical warfare agents. Most of the authors on chemical warfare agents are military chemists and almost without exception leave the impression that no new war gas combinations are to be expected. This volume corrects that impression that has all along been difficult for the nonmilitary physician interested in civil defense to accept, since it is well known that progress is being made in industrial and forestry chemical poisons.

The technical and pathologic descriptions are somewhat condensed, but clarity has not been sacrificed. The psychologic, historical, and economic aspects of chemical warfare agents are more inclusive than the average treatise and make interesting reading.

This volume is timely and will be a valuable aid to those assigned to duty with the Chemical Warfare Services.

CARL W LUPO

The Family Doctor's Notebook. By I J Wolf, M.D. Octavo of 315 pages. New York, Fortuny's, 1940 Cloth, \$2 00

Dr Wolf writes briefly about his life and devotes the greater part of his book to sections on physician and patient, topics of the day, and *quo vadis?* The latter contains a chapter on the patient and religion. The style is rambling and the literary merit of the volume is scant. It will probably have a small audience but the comments of the author on medical problems are sensible and often interesting.

MILTON PLOTZ

Physical Medicine. The Employment of Physical Agents for Diagnosis and Therapy. By Frank H Krusen, M.D. Octavo of 846 pages, illustrated Philadelphia, W B Saunders Company, 1941 Cloth, \$10

The scope of physical therapy is now such that it is difficult to include a comprehensive coverage of the subject in a single volume. Dr Krusen has attempted to do this and has accomplished his purpose in a most creditable manner. He has also achieved an unusual degree of clarity throughout the text and has avoided the more involved aspects of advanced physics. A feature of particular interest is attention to simplified apparatus that makes physical treatment more readily available to the average practitioner. Considerable thought is given to the practical application of the methods under discussion, with adequate detail of technique, indications, and contraindications. A conservative view may be noted throughout the text, which emphasizes the obvious sincerity of the writer. The book is well written, clearly printed, and profusely illustrated and may well be considered an outstanding contribution to the literature.

THE NEW WAR'S NEWEST MEDICAL PROBLEM

Practically every war, since gun powder replaced hand-propelled projectiles, has presented the medical profession with some new type of case. The present conflict is no exception.

In World War I there were gassed cases, shell-shock, trench fever and some others. Among civilian non-combatants, influenza struck to overtax already heavily burdened physicians on the home front and surgery found its problem in reconstructing disfigured casualties.

World War II, has not as yet presented such an array of new medical problems, but it has created a case that no conflict in the past was base enough to produce—the child victim of bombings.

In England, the greatest sufferer so far of air raids, injuries to children have been considerable but even

larger numbers have been "bomb-shocked" casualties. Here then, arose an entirely new problem for medical science to meet. In addition to the customary difficulty of treating infants and the youngest children, the medical profession of England had to devise methods of treatment similar to those used in adult nervous cases, but modified to a child's physical and mental capacity.

"Bomb-shock" made its first appearance among London children during the first air-raids last fall. The usual symptoms were loss of normal equilibrium, inability to walk entirely, extreme nervous tension and uncontrollable sobbing when air-raid signals sounded. Other cities severely bombarded had similar cases among children under five years of age.

Medical veterans of the first World War have de-

Salute to Norway

One ponders at times the fate of the medical profession in the occupied countries of Europe. Out of the dark agony that seems to envelop France, Belgium, Holland, Norway, Poland, and the rest comes no word, no picture of what is happening to the members of the medical profession or any inkling of how they are meeting the ordeal of their captivity, their sojourn in the house of bondage.

The newspaper *PM* for September 25, 1941, carried a special article by Albert Deutsch¹ which permits a brief glimpse of the Norwegian medical profession under circumstances of great difficulty. From this we quote

Several years ago the eminent Norwegian psychiatrist, Dr. Johann Scharfenberg, wrote a scholarly paper on the personality of Adolf Hitler, concluding that the Fuehrer was a madman. Soon after the Nazis occupied Norway, Gestapo agents entered Dr. Scharfenberg's home and asked him point-blank if he still held the same opinion.

"My opinion has changed in one respect," Dr. Scharfenberg replied. "When I wrote my article I believed Hitler was insane. Now I know it."

"Don't you realize your remark is highly dangerous?" asked the Gestapo men.

"Of course," he replied. "But I am an old man, you see. My work is about finished. Now you can do what you like with me. It doesn't matter."

The Nazis spluttered that Dr. Scharfen-

berg would have to report at the local Quisling police station each day.

"Too much trouble," said the grand old man. "Here's my phone number. You can call me daily if you wish."

They threw Dr. Scharfenberg into prison. Every day the good people of Oslo sent many baskets of flowers and food to his cell. It all got too embarrassing for the Quislings, who released the old psychiatrist after six weeks.

PM's staff writer says that he obtained his information by piecing together reports from abroad and from firsthand accounts from recently arrived medical refugees from Norway.

The Dikemark Insane Asylum, near Oslo, is the largest institution of its kind in Norway. Last spring its medical director, Dr. Rolv Gjessing, received a notice from the new Nazi surgeon general, Dr. Ostrem, ordering him to promote a certain orderly to superintendent of male nurses. Dr. Gjessing refused, knowing that the man's only qualification for the job was being a loyal Nazi. After repeated threats failed, the Quisling administration dismissed and imprisoned Dr. Gjessing.

This outrage was followed by one of the most remarkable acts in medical history. The heads of all medical institutions in Oslo signed a manifesto to the Quisling régime declaring their opposition to appointments made on the basis of political allegiance, demanding the immediate release and reinstatement of their colleague, and threatening a strike of the entire medical body of Oslo—more than 2,000 strong—unless their demands were granted.

The Nazis threatened to throw every

¹ Norwegian Doctors "Refuse to Swallow Nazi Medicine." Excerpts from the newspaper *PM*, Inc. Reprinted by special permission.

signer into a concentration camp, but the medical ranks held and in a few weeks Dr Gjessing was reinstated as director of Dike-mark

The Norwegian medical profession has repeatedly joined with organized labor and other groups in bold protests against Nazi tyranny. One such protest, addressed to the Nazi Reichscommissar, Josef Terboven, denounced the brutality of Storm Troopers and mass imprisonments of Norwegian democrats. It was signed by 43 organizations, representing all sections of the people, including the Norwegian Medical Association and the national societies of nurses, dentists, and pharmacists.

The Nazis and their Quisling henchmen have failed time and again to coordinate the Norwegian medical profession. At first they tried to bribe their way into control of the Norwegian Medical Association. This attempt soon proved unsuccessful, and the Quislings then set up, in opposition to the N M A, a national guild that lumped together physicians with natural healers and other quacks of the Julius Streicher type.

Only 15 or 20 doctors entered the Nazi medical guild. When the names of these medical Quislings were made public, most found themselves without patients and several were compelled to attach placards to their shingles repudiating any connection with the new guild.

In a short time the Nazi guild fell apart and the Quisling régime then took over the Norwegian Medical Association by decree.

The existing head, Dr Jorgen J. Berner, was kicked out and replaced by one Dr. Wagner, a Nazi sympathizer.

So now the Norwegian Medical Association, along with nearly all other labor and professional groups, is in the hands of the Nazis. But it is an empty shell, a virtually memberless society, over which the mediocre Dr. Wagner presides. The reputable physicians of Norway have suddenly found it undesirable to continue active membership.

If but a part of this report were subsequently confirmed, *PM* has done the medical profession everywhere a commendable service by publishing it. Doubtless, were the facts obtainable, a similar story could be written of the profession in other conquered countries.

We are particularly interested in the repeated Nazi attempts and their failure to "coordinate" the Norwegian doctors. If the New Zealand conferees are of similar rugged material, the plan of the Ministry of Health of that island to "coordinate" the profession into its pet scheme of free doctor care should not fare too well in practice.

We assume that in any real test the American profession of medicine would be just as insusceptible of coercion as the Norwegian profession, which we salute.

History of the Directory

For the first time, in the current 1941-1942 issue of the *Medical Directory of New York, New Jersey and Connecticut* will be found a condensed history of the *Directory* of the Medical Society of the State of New York.

Published first in 1899, the current volume is the forty-first to appear. The total number of registered physicians in the three states when the directory was first published was 11,625. In the 1941-1942 edition, the total is 32,609. In 1899 New York had 9,199, New Jersey, 1,481, and Connecticut, 945. Today New York has 24,777, New Jersey, 5,332, and Connecticut, 2,500.

In the 1900 edition of this *Directory*

the statement appears on the title page, "Published by the New York State Medical Association." The same statement appears thereafter until, in the eighth volume, 1906, it is changed to "Published by the Medical Society of the State of New York."

For those not familiar with medical society history in New York State, certain events deserve recital here. The Medical Society of the State of New York was organized under an act of incorporation in the year 1807. In 1834, owing to a schism within the ranks of its members, a second state-wide society was formed under the name of New York State Medical Association. Both

organizations continued to function with overlapping membership until, by legal agreement, they were amalgamated in the year 1905. By this agreement the New York State Medical Association went out of existence, transferring its assets and good will to the Medical Society of the State of New York. Since that time the *Medical Directory of New York, New Jersey and Connecticut* has been published by the Medical Society of the State of New York.

This year, for the first time, a Session on the History of Medicine was held at the

Annual Meeting. Reference to the papers read at that time shows the growing interest of New York physicians in this topic. Much history is even now in the making in the state, and it is to be hoped that medical men will take the large view that current archives and Americana are just as valuable as the old.

The editors of the *Directory* have shown commendable imagination and "resource and sagacity," by publishing its history and, by printing the comparative data, have painted a vivid picture of the growth of medicine in the trinity of states.

Warning

The increasing use of drugs of the sulfonamide group has called attention to certain reactions of a febrile and psychosomatic character. It is well that attention be paid to the real source of these reactions in order that they may be attributed to their proper cause and appropriate precautions be exercised.

We have all been taught that when an infection in any part of the body is followed by the development of chills and fever, the chances are that the infecting organism has gotten into the blood stream. In other words, a septicemia has taken place, and this is usually the result of thrombophlebitis. The sulfonamide drugs are now coming into more general use and are being given more frequently and in larger doses than when they were first administered. Certain toxic symptoms of these drugs are widely known. These include leukopenia, a skin rash, and some rise in fever. However, it is not generally known that chills and fever and a severely toxic state may occur in certain individuals who are hypersensitive to any of these sulfonamide drugs. There is an increasing number of cases in which chills and fever, even exceeding 106 F., are due to these drugs. Prompt cessation of administration of the drugs is usually followed by prompt relief. However, if the source of the toxicity is not recognized promptly, the patient may go

on, even to death, and the attending physician remain under the misapprehension that the patient had an overwhelming infection. More and more, physicians are prescribing sulfonamide drugs in the early stages of infection. Under these circumstances, when chills and fever set in, it is vitally important to judge critically the source of the chills and fever. Blood stream infection can be proved by positive blood cultures. Leukopenia, a relatively low leukocytosis, jaundice, anemia, cyanosis, or mental symptoms may indicate drug hypersensitivity. A skin rash resulting from drug reaction differs from that of septicopyemia. The cases are multiplying in which there actually was a blood stream infection with chills and fever—in which the drug has done its work, has eliminated the infection, and then has continued to produce toxic symptoms. The obvious conclusion is to check the blood cultures repeatedly as the drug is administered in these cases and, in instances of doubt, to withhold the drug for twenty-four to forty-eight hours.

It is one thing to write a list of toxic symptoms arising from the use of these drugs. It is quite another, and a much more important thing, to alter our fundamental habits of thinking so that we inquire specifically in a patient who has an infection in any part of the body and then

develops chills and fever whether any sulfonamide drugs have been administered. If they have been given, we must consider the likelihood that the chills and fever may be due to a chemical toxemia rather than to bacterial toxemia.

We are indebted to a correspondent who has called our attention to the necessity for a proper evaluation of the causes of febrile reactions in cases of infections treated with drugs of this group [See page 2156 for Conference on Chemotherapy]

What Price Public Safety?

Now to the disgraceful record must be added one more instance of disregard for the public safety. On April 18, 1941, as we reported,¹ occurred the strike of maids, orderlies, and employees in the nurses' home, the engineering division, and the garages of the West Penn Hospital. A serious situation was created affecting the lives and health of all the patients.

In Kansas City, on September 17, a dramatic power strike blacked out a city of 400,000 inhabitants, plunging its hospitals in darkness for the better part of a whole night and paralyzing its utilities.

This seems to us to be recklessness and irresponsibility of an order that no cause can justify and that must, in the end, utterly alienate public sympathy from labor's just grounds for complaint. There is something peculiarly callous and cynical in actions that subject the sick, the helpless, and the maimed to the additional hazard of fright, terror, darkness, and

violence. It does not, somehow, seem to fit into the picture of the "social gains" of which we hear now and again and which we are given to understand must be protected at whatever cost.

The price seems to us to be too high, as, we are convinced, it will also appear to be to the great majority of American labor which is even now here and there rising in open revolt against the callous tyranny of a rascally leadership. We cannot believe that labor itself will permit, even if civil authorities seem to condone, such irresponsible acts as strikes against the public safety by a small section of its membership. We believe in the good common sense of the rank and file of American labor, who do not have to have us point out that everyone needs tranquil and secure hospitals. We trust that American labor, given the opportunity really to control its actions, will concede and enforce the principle that there is no right to strike against the public safety, any time, anywhere.

¹ Strikes in Hospitals, New York State J. Med. 41: 1618 (Aug. 15) 1941.

Preventing Postoperative Complications

One of the dread postoperative complications is embolus. Patients who have done perfectly well, will suddenly, upon getting out of bed, develop a fatal postoperative embolus. This has led many surgeons to favor instituting activity as soon as possible.

Leithauser and Bergo¹ used early rising and ambulatory activity after operation as a means of preventing complications in 383 appendectomies consecutively performed. On the first postoperative day the patient was assisted to the sitting position on the edge of the bed and then he was made to stand beside the bed for deep breathing exercises. He was

made to walk about the room and made to sit in the chair for a few moments before returning to bed. In each position he was instructed to inhale deeply and cough. The average period of postoperative confinement to bed was from one to one and a half days. The mean hospital stay was $2\frac{2}{10}$ days.

Upon leaving the hospital the patients were ambulatory and returned for observation on the sixth day. Those engaged in light work were permitted to return to their offices on the eighth day and those doing manual labor on the fourteenth day. The authors have been impressed by the freedom from complications and the rapid recovery following this type of management.

¹ Leithauser, D. J., and Bergo, H. L. Arch. Surg. 42: 1086 (June) 1941.

RECENT DEVELOPMENTS IN THE FIELD OF LABORATORY MEDICINE

RALPH G. STILLMAN, M D, New York City

A DISCUSSION of recent developments in any field is fascinating because it stirs our imagination and arouses our hopes, but it may be dangerous because our tendency is to exaggerate the importance of new things and to adopt them before they have been evaluated properly. However, it is our duty to apply them whenever possible, to review the results critically, and thus help to shorten the time necessary for accumulating the information that will fix their true value. In this presentation there will be found mention of some procedures that are almost wholly untried as well as some whose position has been fairly well established and, in addition, reference to a few methods that are not at all new but appear to deserve some attention.

The influence of the diet upon carbohydrate tolerance has long been known, but it appears to have been largely forgotten by the clinician or perhaps has not been called to his attention because the reports have appeared in journals not ordinarily seen by him. Rather recently, however, several articles have appeared on the subject and deserve particular emphasis.

Conn¹ has shown clearly that normal individuals that had been on a preparatory diet containing adequate carbohydrate for three days gave a normal response to the usual glucose tolerance test, but when these same persons were restricted for five days to a diet containing only 20 Gm of carbohydrate daily they yielded a response to the glucose tolerance test that was regarded as typical of diabetes mellitus.

Andrews and Muether² studied patients suffering with typical rheumatoid arthritis and found that their tolerance to carbohydrate was lowered after a low carbohydrate, high fat diet and was raised by a high carbohydrate, low fat period. Langner and Fies³ studied normal individuals using the Exton-Rose one-hour, two-dose tolerance test and short diet periods, and they obtained results that were practically identical with those of Conn in that typically diabetic curves were obtained following even a short period of low carbohydrate diet.

It has been our experience that many clinicians ask for glucose tolerance tests wholly without reference to the previous diet of the patient, and it must often happen that a patient in whom a glucosuria has been discovered will come to a glucose tolerance test after a period of restriction of his carbohydrate intake. Under these circumstances the danger of incorrect diagnosis is greatly increased and astonishing "cures" of diabetes may be encountered. Conn suggests that the glucose tolerance test should be preceded by a period of at least three days during which there should be adequate carbohydrate intake—for example, a diet containing 300 Gm carbohydrate, 80 Gm fat, and 2,800 calories daily. If this precaution is observed, our sugar tolerance tests will be more consistent and reliable.

There is nothing new in hemoglobin determinations except that new forms of apparatus are constantly being introduced for this purpose—notably the photoelectric colorimeter. It is still unfortunately the case that hardly any of the more common laboratory procedures is generally so poorly carried out. This is true not only of determinations made in the doctor's office, sometimes with inaccurate apparatus but more often with hemoglobinometers originally accurate but made inaccurate by neglect, but also of those made in institutions where we would expect technical procedures to be carried out surpassingly well. It must be borne in mind that from the taking of the blood to the final reading the technic presents pitfalls that must be avoided and that many of these are not appreciated by the clinician. One of the worst features, however, is the fact that it is rarely possible to read a report of a hemoglobin estimation and know what the examiner meant by it. Different technics and values have been introduced for this procedure to such an extent that 100 per cent hemoglobin may mean anywhere from 13.8 to 18.0 Gm. per hundred cubic centimeters of blood. When hemoglobin is reported only in terms of percentage without specification of the standard used, the reader often cannot tell whether the patient is anemic or how to calculate the color index. The real reason for this confusion appears to be that most of the authors of methods have attempted to establish 100 per cent as the average hemoglobin

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.
Assistant professor of medicine (clinical pathology), Cornell University Medical College and clinical pathologist, the New York Hospital.

value of the so-called normal male adult and have ignored the wide variations that are due to age and sex. These difficulties will be largely resolved if we will adopt the practice of reporting hemoglobin only in terms of grams per hundred cubic centimeters of blood. Such a report cannot be misunderstood and can be used in the interpretation of the blood examination under all circumstances. Some clinicians will protest because it upsets their previous habit but they should soon become able to think in terms of grams rather than percentage.

When it is desired to have a figure for 100 per cent hemoglobin, as is the case when calculating the color index and certain other indices, it is necessary to rely upon reported observations. When one analyzes the figures obtained in a number of series by different investigators in various parts of the country for "normal" persons of both sexes and all ages, it is found that for each 5,000,000 red blood cells per cubic millimeter there are nearly 14.5 Gm. of hemoglobin per hundred cubic centimeters of blood. It is to be remembered that this does not represent the mythical "normal," for women will average about 13.8 Gm. per hundred cubic centimeters with about 4,700,000 red blood cells and many men will show 16 Gm. of hemoglobin with 5,500,000 red blood cells. For the purposes of certain calculations, therefore, 100 per cent hemoglobin may be regarded as 14.5 Gm. per hundred cubic centimeters. This figure applies to both sexes and all ages. Once the confusion that results from making reports in terms of percentage of a nonexistent normal is recognized, all will wish to record their results in terms of grams per hundred cubic centimeters of blood.

One of the most intriguing of recent suggestions in the field of laboratory medicine has been contributed by Kahn, the author of Kahn's serologic test for syphilis, in what he calls the verification test.⁴ In spite of the undoubted value of the usual Kahn procedure in the diagnosis of syphilis, it is not an unusual experience to have this test yield doubtful or more or less strongly positive results in cases in which it has not been possible to detect any clinical or historical evidence of this infection. Kahn reminds us that the blood of many animals—rabbits, horses, dogs, etc.—yield positive serologic tests for syphilis. He investigated this phenomenon and found that when he carried out these tests at 1 C the results were positive, while if they were carried out at 37 C the results were negative. On the contrary, with the blood of patients suffering with

syphilis the test was positive at 37 C and weaker or negative at 1 C. Kahn therefore concluded that the reaction that is positive at 1 C and negative at 37 C is a general biologic reaction that is present in a certain number of animals and humans and has no significance in the diagnosis of syphilis. In a respectable series of cases his results support his theory, and it would appear that in the verification test the clinician and the serologist have at last been offered a means of clearing away at least some of the difficulties created by doubtful and false positive results with serologic tests.

At the present moment too few cases have been studied to enable us to form a considered opinion of this procedure. At the New York Hospital, in a small series, some carried out by Kahn and some by the hospital laboratory, the results have not been entirely consistent. However, several serologists are investigating the test, and we can expect before long to have sufficient evidence to evaluate it accurately. Moore has objected that in a test that is admittedly nonspecific one can scarcely hope for great improvement to result from a merely technical refinement. Nevertheless, if Kahn's claims are substantiated, an important contribution to the serology of syphilis will have been made.

Of the many new serologic tests for syphilis which are constantly being introduced, the one introduced by Mazzini⁵ appears to have attracted the most favorable attention. The technique of this test is practically the same as that of the well-known Kline slide test, but a different antigen devised by Mazzini is employed. More than 14,000 of these tests have been carried out at the New York Hospital during the past eighteen months, and the results are distinctly promising. Mazzini's procedure yields fewer doubtful and significantly more positive results when compared with the Kline and a complement-fixation test, and the investigation of the clinical accuracy of the findings which is now going on has been favorable. Reports by others seem to indicate that the Mazzini test is superior in both sensitivity and specificity to many of the tests in general use and has the additional advantages of speed and simplicity.

Attempts continue to be made to increase the sensitivity and the rapidity of the methods used to demonstrate the presence of tubercle bacilli. It is said that Meunier in 1898 first suggested the examination of the gastric contents of infants for tubercle bacilli, but it was not until 1931 that the method was applied to

adults. Once so applied it met with immediate success, and there have been many reports of series of examinations which demonstrate the superiority of this method. For instance, Stadnichenko, Cohen, and Sweany⁶ in a group of 1,000 patients, of whom 176 were regarded as nontuberculous, found 307 in whom the gastric contents were positive and the sputum negative. It appears now to be generally agreed that no person should be regarded as having a negative sputum until the gastric contents have been concentrated and examined by inoculation into both guinea pig and culture medium. At the New York Hospital nearly 40 per cent of the specimens submitted for these procedures are gastric washings.

If one adopts this measure, certain precautions should be observed. The cleansing of the tube used in the removal of the contents must be undertaken with great care to avoid the contamination of subsequent specimens⁷ either with tubercle bacilli retained on the inner surface of the tube or other acid-fast bacilli from the distilled water employed, the material should be obtained the first thing in the morning before the patient leaves his bed or eats any food and preferably after exclusion of milk, butter, and cheese from the diet for twenty-four hours, and lavage should be performed with a limited amount of sterile distilled water, the material obtained should be immediately treated or refrigerated, and both culture medium and animals should be inoculated.

At first it was thought that the tubercle bacilli gained access to the stomach because the patient swallowed them, and this is probably the most frequent mechanism. Ulmar and Ornstein,⁸ however, showed by x-ray studies that even in the absence of cough it is possible for bronchial secretion to reach the esophagus and thus be collected in the stomach and thought that this is due to peristaltic action of the trachea and the bronchial tree. It seems more likely, however, that it is due to the action of the ciliated epithelium. This action occurs rather more effectively when the patient is lying down.

Two of the most important advances in recent years have been the discovery of vitamin K and its action in preventing hemorrhage through stimulation of the production of prothrombin. This work has been greatly facilitated by the introduction by Quick and by Warner, Brinkhous, and Smith of methods for the determination of the relative amount of prothrombin in the blood. The latter method

is much more complicated but is generally accepted as being more reliable than those of Quick, though the Quick methods have the advantage of being more rapid and of requiring less special apparatus. It has been quite definitely shown that prothrombin is produced in the liver, that it is constantly being used up or destroyed, especially in the lung, that it is not stored in the body in appreciable amounts, and that hile salts are necessary for the satisfactory absorption of vitamin K from the intestine. It is also now known that the hemorrhages occurring in hemorrhagic diseases of the newborn and in obstructive jaundice are due to prothrombin deficiency and, if the liver is not too seriously affected, this deficiency can be corrected by the administration of synthetic vitamin K (2 methyl-1,4-naphthoquinone) and hile salts by mouth or of the former alone by intramuscular injection.

It also appears to be the case that if the prothrombin content of the blood fails to show a satisfactory increase after the administration of this synthetic vitamin it may be assumed that there is a deficiency in the function of the liver, and the degree by which the prothrombin fails to return to normal is a rough measurement of the extent of the liver damage. Just how reliable this procedure is as a measure of liver function is now the subject of study in a number of laboratories, and there have recently been published⁹ some observations that appear to contradict this thesis. It is quite possible that like the other tests that have been proposed for studying liver function this procedure will be found to be subject to a number of qualifications and limitations.

The introduction of the falling drop method for the determination of the specific gravity of the serum¹⁰ and the use of this figure in estimating the protein content and, thus, the concentration of the blood have greatly facilitated investigation in this field. It has long been appreciated that the colorimetric method of Greenberg is subject to a fairly large error and that the Kjeldahl method, while highly accurate, is more time-consuming and elaborate than is desirable for a clinical method. The specific gravity method appears to be sufficiently accurate for all clinical purposes provided one takes care not to be misled by bloods containing an unusually large amount of glucose or cholesterol. The determination of serum proteins is recognized as an important procedure not only in the demonstration of the edema level but also in heralding the approach of surgical shock and, more recently, in detecting a low or falling serum protein, espe-

cially in patients suffering from carcinoma of the gastrointestinal tract. It has been found that the low serum protein in these diseases is an important factor in determining an unfavorable outcome, especially after operative procedures, and, if this can be overcome by the transfusion of concentrated plasma, the mortality rate can be lowered significantly. Determinations can be made in a minimum of time with this method, and it has been quite largely adopted as a standard procedure.

Determinations of phosphatase in the blood have been carried out for a number of years, and the significance of the findings has been fairly well settled. Recently, it has been shown that there are many phosphatases in the body, among them one found in the substance and the secretion of the prostate which is most active in an acid medium (pH 4.9). Gutman and his coworkers¹¹ have shown that the blood content of such an "acid" phosphatase is usually increased in patients suffering with carcinoma of the prostate when metastases have developed in the bones. Other conditions that show an increase in the acid phosphatase are hyperparathyroidism, well-advanced Paget's disease of the bones and, rarely, bone metastases from tumors in other locations. These authors present a large series of cases in support of their theory, and it seems likely that there is here a method for detecting the development and spread of bone metastases from prostatic carcinoma.

The creatine tolerance test is not a recent appearance in laboratory medicine, but it seems to be not so well known or so frequently used as it deserves to be. Its principal application is in disturbances of the thyroid gland in which, at times, it proves to be more reliable than the far more popular determination of the basal metabolic rate, which is sometimes not carried out in an accurate manner. There is a diminished tolerance to ingested creatine in hyperthyroidism, and this is readily restored to normal by the administration of iodine. A similar abnormality occurring in progressive muscular dystrophy is not abolished by iodine. In myxedema there is excellent tolerance for ingested creatine which may be lowered, at least temporarily, by the administration of thyroid. This procedure is not technically exceedingly difficult, but the laboratory should have some experience with it and all details in the directions should be strictly adhered to.

The introduction of sulfanilamide and its numerous derivatives naturally required that

a method be devised for the determination of the concentration of these substances in the blood, other body fluids, and the urine. Bratton and Marshall's method¹² has proved to be adequate for the purpose and is well suited for the derived compounds so far as we have tested them. It is necessary to remember that the request for examination should state the name of the drug that the patient is receiving, since much confusion arises when this is not done. Only the free form of the drug is effective so that determinations in the blood need not include the combined (acetylated) form.

The occurrence of renal calculi during the administration of some of these drugs—namely, sulfapyridine, sulfadiazene, and sulfathiazole—has been noted so often that the microscopic examination of the urines should be carried out frequently and thoroughly when these compounds are given. Unfortunately, there is a great deal of confusion concerning the crystal form assumed by them in the urine, and it is likely that the same substance may appear in more than one form. It may be said that if one detects crystals in the urine which cannot be identified as of a form ordinarily found there they are likely to be those of the drug being given. These crystals are colorless or yellow, may appear as broad or fine needles arranged in wedges or sheaves or sometimes built up into irregular balls or dumbbell forms, and have at times been mistaken for acid ammonium urate. They may be present in truly enormous quantities, the sediment forming as much as 10 per cent of the total volume of the urine.

Complaints have been made that when patients are receiving large quantities of sulfanilamide or one of its derivatives it may be impossible to culture organisms from the blood, urine, or spinal fluid, even though they may be present, because of the bacteriostatic effect of the drug in the material. During the past year it has been discovered¹³ that sulfanilamide is completely neutralized by *p*-aminobenzoic acid and, recently,¹⁴ it has been shown that the addition of this substance to culture mediums may lead to a success in the cultivation of organisms which would otherwise be impossible. It is claimed that the presence of *p*-aminobenzoic acid in the proportion of 5 mg to 100 cc of culture mediums will not inhibit the growth of any organisms and will completely neutralize the bacteriostatic effect of any sulfanilamide or derivative that might be present in the material. The claim has not yet been fully substantiated but is supported

by excellent evidence. Meanwhile, it would be wise for laboratories to use this medium in addition to those ordinarily employed when culturing materials derived from a patient receiving a compound of this group.

The methods that have been used for the cultivation of anaerobes have long been a source of dissatisfaction to bacteriologists because of their awkwardness and complexity. Clear liquid mediums that may be used for this purpose have been introduced in the past but for the most part require an elaborate method of application and maintain anaerobiosis for only a short period of time. To meet this situation, Brewer¹⁵ has devised a medium, which has come to be known as Brewer's thioglycollate medium, which appears to be nearly ideal for this purpose. This product remains anaerobic for more than a month, except for a thin surface layer, and will support the growth of the most strict anaerobes as well as if contained in an anaerobic jar. It has been found that "80 cc of sterile air per minute can be bubbled through a tube of the medium for thirty minutes and it will still support the growth of *Clostridium novyi*, one of the most strict anaerobes." In a rather limited use at the New York Hospital this medium has proved to be entirely satisfactory, and its introduction will be the source of much convenience and benefit to bacteriologic laboratories.

Discussion

Dr. Ward J. MacNeal, *New York City*—I should like to emphasize the value of a culture medium containing a neutralizing substance when making blood cultures on patients under treatment with sulfonamide drugs. These drugs may exist in the patient's blood in sufficient amount to delay or prevent the development of bacteria in the culture, and one may fall into the error of believing that the blood has become bacteria-free when such is not the case.

SCIENTIFIC EXHIBITS

1942 Annual Meeting

Applications for space for the scientific exhibits should be made directly to

Dr. J. G. Fred Hiss,
505 State Tower Building,
Syracuse, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee

The Annual Meeting will be held April 27-30, 1942, Hotel Waldorf-Astoria, New York, New York. The list will be closed on January 1, 1942.

PETER IRVING, M.D., *Secretary*

PRINCIPLES OF TREATMENT OF EPILEPSY

With Particular Reference to the Surgical Aspect

WILLIAM P. VAN WAGENEN, M.D., Rochester, New York

EPILEPSY represents a physiologic insurrection and rebellion within the nervous system. Like its political counterpart, a revolt may start at any of the levels of government and spread far or remain local. The provoking incidents may be varied and manifold or they may be the same each time. The treatment may have to be on the basis of a broad change directed at all levels or it may be directed toward the eradication or isolation of an offending party.

Classifications of Epilepsy

A The variations of epilepsy may be classified in several different ways. The oldest and still best-known classification is that of petit mal, grand mal, and the epileptic equivalent. While such a division of the subject is a purely descriptive clinical one, it has the backing, in part, of investigators in electroencephalography who find fairly characteristic wave form changes in each of these types.

B A classification on the basis of known etiologic agents leads to a clearer thinking and a better understanding of the therapeutic problem at hand. Year by year some item is taken out of that catch-all basket called idiopathic epilepsy and given the standing it warrants on a pathologic or physiologic basis. Brain tumor of slow growth was once, and even now is, occasionally considered to be idiopathic epilepsy until an eventual diagnosis is made.

I. Intrinsic Organic Nervous System Lesions Associated with Epileptic Seizures.

1. Space displacing masses.
 - (a) Tumors, largely cerebral.
 - (b) Cysts of the pia-arachnoid—congenital, infectious, or traumatic.
 - (c) Cysts within brain—hemorrhagic, infectious, neoplastic, or congenital.
 - (d) Granulomas
2. Cicatrices
 - (a) Traumatic
 - (b) Infectious.
 - (c) Posthemorrhagic
 - (d) Ischemic

3. Infections
 - (a) Spirochetal
 - (b) Virus.
 - (c) Pyogenic
 - (d) Granulomatous
4. Degenerations.
 - (a) Diffuse and progressive—cause unknown.
 - (b) Isolated and stationary—cause unknown.
5. Vascular changes.
 - (a) Arteriosclerotic
 - (b) Angiospastic
 - (c) Congenital anomalies.
6. Congenital anomalies of brain.
 - (a) Microgyria—nonischemic in origin.
 - (b) Agenesis of cerebrum, local or diffuse.

II. Extrinsic Nervous System Agents Associated with Epilepsy

1. Toxins and/or poisons
 - (a) Febrile
 - (b) Metals and gases.
 - (c) Drugs and chemicals
2. Disturbances of metabolism.
 - (a) Water
 - (b) Carbohydrates.
 - (c) Proteins as in phenyl-pyruvic acid
3. Anemia—cerebral.
 - (a) Associated with heart disease
 - (b) Angiospastic

III. Idiopathic Epilepsy

1. Etiology is as yet not understood but is probably of intrinsic nervous system origin.

C A third classification may be made on the basis of disturbance of the electroencephalographic findings. This classification most nearly corresponds to the gross clinical type of petit mal, grand mal, and epileptic equivalent, for each of these types of fit has a reasonably constant pattern.

D A fourth classification essential to the surgeon is that based on the anatomic location of the origin of the fit and the level or levels involved so far as they can be determined. Certain telltale symptoms or observations may often lead to this information. The faithful recording of the events in a fit, particularly before consciousness is lost, by nurses, house staff, and attending physicians is of great importance in this regard.

1. Perioral motor areas—with focal or "marching" motor phenomena

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941

From Department of Surgery, Neurosurgical Division, University of Rochester School of Medicine and Dentistry and Strong Memorial Hospital.

2 Postrolandic sensory areas—with focal or "marching" sensory phenomena

3 Occipital and temporal areas—with hallucinations of light, formed and diffuse

4. Temporal areas—with hallucinations of sound, formed and diffuse, with perceptual delusions of person and place, with dream states, and, questionably, with disturbance of attention

5 Olfactory areas—with hallucinations of smell

6 Frontal—with psychic fits without motor component (?)

7 Diencephalic—with disturbances of autonomic nervous function and with simple transient partial loss of contact with environment (?)

8 Mesencephalic—with fits of decerebrate postures

9 Bulbospinal—with gross myoclonic fits

Mode of Spread of a Fit

A great deal of information, clinical and laboratory, points to the belief that the disturbed wave of electrical impulses thought to give rise to a fit travel by way of nervous pathways. Nothing to the contrary has yet been proved. However, it could be conjectured that other types of electrical waves giving rise to a fit could pass through fluid medium of the brain much the same as radio waves pass through the ether. For the present, however, we must proceed and work on the principle that anatomic conduits are the only means of spread of a fit.

Where the fit has its origin in the cortex, the spread may be downward into the basal ganglia and diencephalon, giving peripheral manifestations of abnormal function of one or all of these levels. The reverse would also seem to be true. Fits starting in the basal ganglia may spread upward to the cortex and be reflected from there to appropriate areas. By piecing together bits of information, it would appear that the first effect of the abnormal wave originating in or striking an area was one of stimulation followed by one of paralysis. The wild tonic and clonic movement of an arm or leg may be followed by palsy. The most dramatic of the paralytic effects, if such it be, is the loss of consciousness. No one knows with certainty where the seat of consciousness lies or if it lies in any one discrete area. There is some good evidence pointing to a posterior diencephalic and upper midbrain residence. On the other hand, large cortical lesions, suddenly produced or stimulated, are associated with loss of con-

sciousness. Manually occluding the middle cerebral artery when exposed in the sylvian fissure under local anesthesia may lead to a rapid temporary loss of consciousness. The same is seen in embolic phenomena, though the loss of consciousness is much longer.

It must not be assumed that the site from which the first clinical symptoms arise during a fit is necessarily the site of its origin, for the abnormal wave may simply "bump" into a symptom-producing area on its way elsewhere. Only too frequently are motor phenomena a first hint of a fit from a scar in the frontal pole.

Principles of Treatment

The principles of treatment of epilepsy in a given patient must naturally vary with the concept of the disease in that person. It cannot be too strongly emphasized that each case is just as much an individual problem as a tumor situated in various levels of the nervous system would be.

Principle I Eradication of "Firing Points"
—Since at the present day it is held that a particular fit starts in one area, this area may be considered for surgical eradication where its location makes this possible. Examples are neoplasms, cysts, and scars. All too frequent is the observation that as soon as one offending "firing point" is eradicated another one just as potent assumes control. This is particularly true of brain scars.

Case Report

Case 1—G F H., a boy aged 17, had a chief complaint of "spells." His birth history is as follows. The patient was delivered by instruments. The head was molded until "it looked like a Zeppelin," the chin being one point and the occiput the other. One blade of forceps was over the right eye and the other was over the left occiput. There were large bruises at each point, the eye being swollen shut. These bruises did not clear up for about three months. As a baby he was "very nervous" and slept but little.

Two to three weeks after starting school at the age of 6, he had the first attack of spells. He felt rather unwell, and several times during the day he had a slight gnawing sensation in the region of the right temple which came on without warning, lasted a few seconds, and left no sequelae. This was repeated again in two to three weeks. His physician prescribed certain pills that resulted in the disappearance of these symptoms for a few weeks. The feeling of being unwell then became so severe that he had to leave school on the days that he had the attacks, and he has never had a full year of schoolwork since. The early attacks, which were called "little spells," lasted until he was 9 or 10 years old when he began to have "big spells."

FIG 1 Photograph of patient during hospital stay in 1929 showing facies and operative wound.

The big spells consisted of the same gnawing sensation in the right temporal region as before but lasted longer and ended with a period during which he would see flashes of light "just like lightning" out of the temporal corner of the right eye. At first he remained conscious throughout the attack, but later and especially more recently—that is, 1929—he has had spells during which he felt numb all over and knew nothing of his surroundings until the end of his attack. He has never fallen and has no other signs to give evidence of falling during an attack. He has had attacks, however, while riding a bicycle through traffic but by some miracle escaped without serious injury. The longest period of freedom from attacks has been three months. Treatment has consisted of many forms of medication. Each medicine prescribed would have a mild beneficial effect for a short period of time.

During the year prior to admission in 1929 he lost weight and became depressed, morose, combative, and at times assaultive. Some of these attacks of depression would be accompanied by a sense of dizziness during which the floor seemed to rise in front of him and appear higher the farther away that it went. Following the big spells he would have severe headache and be fairly lethargic for a period of hours. He had had incontinence during the night until the age of 7. This stopped but began again with the onset of big spells at the age of 9 or 10 and continued until the age of 15.

The patient was thought to have a left occipital lobe scar. The entire occipital lobe was excised on March 7, 1929. He had freedom from any attacks until September, 1939, when he began to have petit mal attacks again. He has not had a return of grand mal attacks (Fig 1).

Principle II "Blanketing"—Where there are thought to be many irritable foci—these located in different levels of the nervous system—the principle of "blanketing" must be resorted to. Particularly true is this of the patient with petit mal, as well as grand mal,

fits or equivalents. The use of drugs to lower the receptivity of nerve cells to incoming stimuli is well known. Whether drugs lower the discharge rate or potency of the irritable focus is not known. Bromides, phenobarbital, dilantin, and the products of an acidosis are well known to you all. Illustrative cases of the benefits of such medication can doubtless be had from the practices of every doctor in this field. A word may be said against the continued use of these drugs when reasonably effective results are not forthcoming in a few weeks' time.

Principle III "Counterstimulation"—Another well-known age-old principle is that of neutralizing stimuli from a "firing point" by counterstimuli from a peripheral somatic area. Many an epileptic has learned some trick to "ward off" an attack—such as rubbing the hand vigorously, getting into a hot tub of water, or drinking some favorite, often nauseating, mixture.

The recognition of the periodicity of epileptic seizures in certain people has been recognized since the beginning of medicine itself. This periodicity has been associated with the menstrual cycle. There cannot be any question of the coexistence of seizures with the menstrual cycle at times. For this reason the device of electrical shock producing a seizure periodically has been resorted to. Reports on this procedure are of relatively recent date for final evaluation.

Principle IV "Ditching"—The principle of "ditching" is an old one in fire fighting and one that I have been most interested in of late. It consists of trying to prevent the spread of an epileptic fit by surgical section of association pathways where this is possible. The pathways amenable to this are the corpus callosum and anterior commissure and the fornix sys-

tem The case selected is one where the firing point or points seem limited largely to one hemisphere and where the offending area or areas cannot be eradicated without serious neurologic consequences—such as palsies and speech disturbances. The theory behind this procedure is the often-made observation that where the fit remains localized to one hemisphere the patient does not tend to lose consciousness.

This work was undertaken with moderate trepidation, inasmuch as these pathways were considered as fairly holy ground and certainly not fit for a surgical desecration. Portions of these association pathways have been sectioned from time to time by various surgeons incident to tumor removal. On a basis of more than 25 cases, I can assure you that these pathways are not sacrosanct and may be divided without untoward effect—such as the production of a motor aphasia, apraxia, alexia, dissociation of motor movements, astereognosis, permanent incontinence of bladder or bowel, or the onset of the so-called Korsakoff's syndrome, the onset of cortical deafness, etc.

It must be realized that the corpus callosum and the anterior commissure are not the only interhemispherical association pathways. A fit may spread via the habenular, the posterior commissure, and by midbrain pathways. It must also be remembered that a fit originating in basal ganglia or diencephalon may discharge upward into each hemisphere whether the mentioned association pathways are intact or not. Assuming that there are firing points in each cortex, there is no reason why each of them may not "fire" simultaneously and a generalized fit result. We have seen a patient with a partially divided corpus callosum have a series of Jacksonian fits on the right one day and on the left the next and, with hydration, have the one side begin with a fit be followed by a similar one on the other, and a grand mal attack result.

The problem of limiting the spread of a fit known as an epileptic equivalent by means of a prefrontal lobotomy is under investigation and is worthy of a real trial.

While any procedure carried out on an epileptic patient takes years to evaluate and numbers to argue from, I am convinced that this procedure has a real place in the surgical attack on this problem. Work on the problem of eliminating the epileptic equivalent type of fit by prefrontal lobotomy or similar white fiber section is in its beginning. A further report on this will be made at a later time.

Case Report

Case 2—E C C, a single woman aged 28, was first seen in this hospital on September 26, 1938, at which time she complained of convulsions of some five years' duration. The patient states that she was in good health until some six years prior to 1938, when she was in an automobile accident and struck her head against the roof of a car. The accident was not a severe one and the connection of this accident with the complaint of convulsions is dubious. The first convulsive seizure was a grand mal attack coming on during sleep and lasting some five to ten minutes. Seizures had continued from that time until the date of operation on November 6, 1939. At times the convulsions began with a sensation of numbness and tension in the left face followed by clonic contractures of the left side of the face which spread to the left arm and leg and then became generalized. The patient usually lost consciousness with an attack, hit the tongue, occasionally lost control of the sphincter, and had a period of drowsiness following the seizure. The physical examination gave evidence of a slight left-sided atrophy of the arm and, to a less extent, of the leg. There was a slight facial weakness of the left lower side. A ventriculogram gave evidence of a diffuse atrophy in the region of the right temporoparieto-occipital area (Fig 2). The patient had been taking sedatives of various types since around 1933. She had been tried on a ketogenic diet, limited fluid intake, and daily magnesium sulfate administration, all without any particular effect on the seizures. On November 29, 1939, the corpus callosum was completely divided, together with one limb of the fornix. The patient has not had a grand mal seizure since that date. She has had numerous unilateral seizures consisting of numbness of the entire side and a few tonic and clonic movements of the left arm and leg but never with loss of consciousness. Her ability to think, reason, remember, calculate, etc., is intact. Physically, she is as intact as before operation. There is no evidence of an astereognosis or an apraxia.

There are many interesting and fascinating side chains to this study which cannot be gone into at this time. The effect of association fiber section on the speech disorder of stuttering is one. If stuttering is a fight for dominance between hemispheres, a section of the corpus callosum might be thought of as a means of stopping it. Such is not our experience in 2 cases. The speech disorder goes on unchanged.

Principle V Blanketing by Means of Altered Metabolism—Another principle of treatment of the epileptic not suitable for surgical eradication of firing point or ditching is that of alteration or blanketing of the cell

FIG 2 CASE 2 Ventriculogram films to show the dilation of the right temporo-occipito-parietal lobe of the brain

receptivity by the products of acidosis. High fat diets and limitation of water intake fall within this category. Numerous papers since those of McQuarrie and Fay have dealt with the relation of hydration to the epileptic state. As a result of experimental work on diabetes insipidus carried out by Dr. Rowland Bellows and myself, I believe that it is a chronic dehydrating disease. The bodily water transport is large, and the water balance tends to be a negative one. Proceeding on this theory, work is underway to treat surgically a group of hopeless epileptics by producing a state of diabetes insipidus. The procedure is in the period of trial, and reports on it will have to be made at a later date. Incident to this is a study by the Medical Service—Drs. Keutmann and Kaltreider—of the distribution of water in the intercellular and intracellular spaces in diabetes insipidus by means of the radioactive sodium method, as well as the other better known methods.

Case Report

Case 3—J. B., a single man aged 24, had a chief complaint of epileptic seizures for nine to ten years. He has had many petit mal seizures, as well as grand mal attacks. The patient has been observed in a number of instances in which he was in *status epilepticus*. Needless to say, this man has been studied from every point of view. He has had every known form of treatment *in extenso* without any appreciable change in his condition. The neurologic examination was essentially negative. From the mental point of view the man was much deteriorated. He was able to do certain things with quite a good deal

of facility—such as carrying out card tricks and amusing others about the ward. He was extremely religious and could pray with a great deal of fervor. He was able to sing a number of songs and at one time participated in a small act in vaudeville. The electroencephalographic record gave evidence of numerous petit mal attacks, as well as grand mal seizures. All the details of laboratory findings will not be gone into at this time. Suffice to say that he has been studied with particular reference to the intracellular and extracellular water content by the Medical Service. The method employed has been that of estimation of radioactive sodium in these spaces. On April 21, 1941, a craniotomy was done, at which time a hypothalamic puncture was made at the upper end of the pituitary stalk. The approach was through the corpus callosum, which was divided from the junction of the body of that structure with the fornix. The anterior commissure was divided and the right limb of the fornix. The patient developed the primary phase of a diabetes insipidus. The secondary phase is just beginning. The patient has taken as high as 6,000 to 7,000 cc of fluid a day. Up to the present time he has not had a convulsion. It is appreciated that this patient is early in his post-operative course, and no deductions are being drawn regarding the ultimate result.

This patient is one of the few hopeless epileptics who have been treated in the last few years by means of punctures or lesions of the pituitary stalk designed to bring about a diabetes insipidus. The individual, G. T., who was operated upon some four to five years ago has not had a grand mal seizure since, except associated with a hypoglycemia. The hypoglycemia is due to a lesion of the pituitary body.

itself and subsequent atrophy of the adrenals.

I believe that it can be stated with certainty that any epileptic that we have ever seen would have had a series of severe convulsions in the postoperative state had he been hydrated to the extent that the patient J B has been.

Summary

The direct surgical attack on a known or proved single firing point from which a fit is thought to start is obvious, where it can be done, and should probably have first consideration among surgical procedures. Methods of search for a firing point, such as a scar, are laborious and time-consuming and often fruitless. The history may give a lead suggesting the neighborhood of origin of the fit. Distant foci setting up waves that "bump" the area must ever be remembered. The electroencephalogram in experienced hands may give a clue to an area of persistent abnormal waves, and from this the presence of a firing point may be suspected. Air encephalograms may aid in picking up scars by revealing areas of cortical or subcortical atrophy. Stimulation of the suspected area after a craniotomy, under local anesthesia, may confirm the site of the focus by producing a fit typical of that complained of. The use of the electroencephalogram on the exposed cortex is one with which I have not had experience.

Eradication of the "firing area" is not always simple. Excision of one scar may lead to a larger one. Wherever possible, the crater of the excision should connect with a ventricle in order to permit it to fill with a pool of cerebrospinal fluid. Various devices are in order to prevent a reforming of adhesions between the dura and brain—such as the use of amniotic membrane, peritoneum, etc. The presence of one proved scar or firing point does not necessarily mean there are not others that are only too ready to carry on. Particularly is this true in the scar of traumatic and infectious origin. Eradication of a true firing point has the advantage of limiting, and perhaps abolishing, bombardment of the basal ganglia and diencephalon by abnormal brain waves leading to unconsciousness.

Should clinical and laboratory studies give evidence of a widespread hemispherical scar too extensive for excision, or in a zone not amenable to surgical removal, a section of certain major association pathways is certainly in order, inasmuch as it can be done without any more serious consequences to the patient than removal of a scar.

Should the patient be thought to have fits originating in the basal ganglia or diencephalon, an alteration of water metabolism by means of a suitable hypothalamic puncture may warrant consideration after other usual medical measures have failed.

Surgical Technic

The surgical technic of scar excision, association pathway section, and hypothalamic puncture for the production of diabetes insipidus is too extensive to be dealt with here.

Selection of Cases for Surgical Attack

The selection of cases for surgical attack is one that is bound to vary from clinic to clinic depending on the facilities and interest of the personnel. All agree that every search should be made for extracranial faults—such as altered metabolic states, infection, etc. A fair trial of methods of blanketing is in order in most instances. When the blanket becomes too heavy or is ineffective, the possibilities of surgical methods outlined are worthy of real consideration.

Discussion

Dr Eldridge Campbell, *Albany, New York*—There is no greater problem in medicine today than epilepsy. From the study of this dreadful malady in the past have come not only many efficacious methods of treatment but also several important advances in the physiology of the central nervous system. It is to be recalled that from an analysis of the march of the fit, Hughlings Jackson first postulated the existence of the motor area itself. From Dr Van Wagenen's report of the effect of corpus callosum section, at least two points of practical neurologic significance have emerged. In the first place, the entire corpus callosum may be divided with the same impunity that Dandy has found in sectioning the posterior two-thirds. This is rather surprising in view of the older teachings and of the mental symptoms that usually accompany gliomas involving this structure. In such instances, invasion of the adjacent cerebral hemispheres must play a large role in the production of apraxia and astereognosis. Secondly, division of the forward portions of the corpus callosum affords an advantageous route for the removal of tumors in the anterior portions of the third, and even of the lateral, ventricles.

It is important to consider epilepsy a symptom. As such, it is of particular interest to remember that fits may be, and indeed often are, for long the only manifestations of a brain tumor. Just recently, I removed a huge temporo-occipital lobe glioma from a 50-year-old man whose only symptoms for seven years had been occasional generalized fits. Of all the patients with cerebral

tumors operated upon at the Albany Hospital, 24 per cent had convulsions as a prominent symptom, and in several instances these long preceded any other complaint. One patient had had Jacksonian seizures for ten years, and several had been so afflicted for more than five years before the tumor had otherwise announced its presence.

Indeed, in this group the average duration of convulsions prior to admission was nineteen months.

It is well to remember then that the onset of convulsions in a person past the age of 35 should mark the patient as a brain tumor suspect until proved otherwise.

NOTED ENGLISH PSYCHIATRIST TO LECTURE HERE

Dr R. D. Gillespie, who is now chief psychiatrist for the British Royal Air Force, is coming to this country at the request of the Salmon Committee on Psychiatry and Mental Hygiene of The New York Academy of Medicine. He will deliver the Salmon Memorial Lecture in the New York Academy building November 17 and 18, speaking on "Psychoneuroses from the Standpoint of War Experience."

Dr Gillespie's observations made under actual war conditions are expected to be of inestimable value to American psychiatrists in formulating plans for maintaining civilian morale in wartime. His lectures will also give his hearers new information concerning the pressing psychiatric problem of today—the psychoneuroses.

Dr C. Charles Burlingame, chairman of the Salmon Committee, which each year chooses an outstanding specialist in psychiatry, neurology, or mental hygiene for the Salmon Memorial Lecture, has issued a general invitation on behalf of the committee to members of the medical profession and their friends to attend. Dr Gillespie will be the ninth lecturer who has been selected from the top-ranking psychiatrists and neurologists throughout the world who have made the greatest contribution to their field.

during the preceding year. Selection for delivering the Salmon Lecture has been likened to selection for the Pulitzer Prize in letters.

Dr Gillespie is the author of two medical volumes *Disorders in Sleep* and *Textbook of Psychiatry*, a reference work in collaboration with Dr D. K. Henderson, of Edinburgh, who is a former Salmon lecturer. Before he undertook his wartime duties as chief psychiatrist for the R.A.F., Dr Gillespie was the lecturer in psychologic medicine at Guys Hospital and Medical School in London. He was also the lecturer in psychopathology at the University of Aberdeen. He received his medical degree from the University of Glasgow and his doctorate in psychologic medicine from the University of London. He is a member of the Royal College of Physicians.

Among Dr Gillespie's many important findings concerning the psychologic effects of modern warfare on civilians and combatants is the fact that chronically neurotic people and those suffering from mild depressions have become chronically heroic and self-sacrificing under the stress of bombing raids. Also, he has noted that women stand up as well if not possibly better than men under civilian bombings.

CHILDREN'S BUREAU NEEDS MATERNAL AND CHILD HEALTH SPECIALISTS

Employment registers are to be established by the Civil Service Commission to fill maternal and child health specialist positions in the Children's Bureau of the Department of Labor. Vacancies in similar positions in state agencies cooperating with the Children's Bureau may also be filled from these registers at the request of the states concerned. The examination announcement just issued by the Civil Service Commission to recruit persons for these positions allows the filing of applications until November 15, 1941.

There are three options in which persons may qualify—pediatrics, obstetrics, and orthopedics. For each of these options employment lists will be established for administrative, research, and clinical positions. The duties of the administrative positions include giving consultations and advisory service to state and other government agencies carrying out maternal and child health programs. The research positions involve the planning or directing of studies in such fields as infant and maternal mortality and child

growth in relation to social, economic, and other factors. Persons appointed to clinical positions will do clinical work in one of the options.

A written test will not be given for these positions. Competitors will be rated on their education, experience, and corroborative evidence. Applicants must have graduated from a medical school of recognized standing with an M.D. degree and must have served a one-year internship. In addition, they must have had full-time postinternship clinical training as well as other appropriate experience in the option selected and in the type of work in which they seek appointment.

Doctors of medicine who are interested in this opportunity for government employment are urged to seek further information about these positions, which pay from \$3,200 a year to \$5,600 a year. Further information and application forms may be obtained from the Commission's representative at any first- or second-class post office or from the central office in Washington, D. C.

OXYCEPHALY

JOSEPH E J KING, M D , New York City

IN NOVEMBER, 1937, I made a preliminary report of a new operation for oxycephaly in a paper read before the New York Neurological Society in the Section of Neurology and Psychiatry of The New York Academy of Medicine. In this paper a case operated upon by this method was reported, including the details of the operation and the follow-up record for a period of a few months.

A later report will now be made after a period of about four and one-half years, together with a report of another case that I operated on and other cases operated upon by colleagues.

In the original, indications for operation were reviewed, as well as a brief description of the operative procedures that had previously been employed in the hope of relieving this condition. None of the operations appeared to have been followed by good results. Since publication of my paper in 1938, a number of papers on the subject have been published, these have been reviewed. Only a small amount of space has been devoted in any of these papers to relief of this condition by operation. Subtemporal decompression was mentioned more than any other operation, and this afforded only temporary relief.

Therefore, I wish to bring to your attention further information regarding the proposed operation that worked so well in the first case and that has had equally good results in some other cases operated upon by colleagues.

Case Reports

Case 1 —E. C. was operated upon at the age of 8 years on November 10, 1936. When he was 3 years old he had sustained a fracture of the right femur, for which three attempts at reduction, both open and closed, had been made before admission without effect. There was present a malunited fracture of the femur on admission. After recovery from the operation for oxycephaly the malunited fracture was operated upon with a good result.

A recent report on this patient has been obtained, together with his photograph and x-ray films of the skull. This boy is now 13 years old, is well developed, and is attending school. His grandmother states that he keeps well and has not missed a day at school. He wrote me a letter

from his home in Halifax, Nova Scotia, dated January 28, 1941, as follows:

"I was glad to hear from you. Since I have arrived home from the States I have been feeling fine. In school I have been doing pretty well, but I suppose I could do better. My leg is feeling stronger now. There is plenty of ice, so I do lots of skating.

"Grandmother was glad to hear from you. Enclosed you will find the x-rays and the pictures which you wanted, and my examination papers. I am ending, hoping you are all well. Remember me to Dr.

Yours truly,
Eddie "

He is in Grade 5. He sent me his examination paper in spelling, and most of the words were correctly spelled.

These simple facts are reported for the reason that this boy had had but little schooling before his operation, and had not attended school for at least a year before the operation on his head. Most significant, however, was the fact that he was almost blind and could not distinguish the features of one standing at the foot of his bed. About six months following the second stage of the operation, he was able to recognize a person as he entered an assembly hall at a distance of 100 feet or more.

The results four and one-half years following operation on this boy are most gratifying.

Case 2 —E. H., a negro boy aged 5, was admitted to Lawrence Hospital, Bronxville, New York, on October 17, 1940.

The birth of this child was apparently quite normal. There were 12 other children in the family, with 7 living. A brother, 6 years old, showed an elongated, flattened skull but was otherwise in good condition. There was no history of oxycephaly in the family. Lumbar puncture and encephalograms were not considered necessary.

Examination revealed a child, intelligent for his age. General and neurologic examinations were negative. There was slight bulging of his eyes, but this was not marked. The intrinsic and extrinsic eye muscles were normal. X-ray films of the skull previously made by Dr. C. I. Headland, who referred the case, revealed the following:

"Films made of the skull in the anteroposterior and posteroanterior and both lateral directions show a high, pointed skull of the type known as oxycephaly (Figs. 1(a) and 1(b)).

"This is due to premature ossification of the suture lines. As a result, increase in the size of the brain causes increase of pressure within the cranial vault with resulting protrusion upward in the region of the junction of the coronal and

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

Director of neurosurgery, Second Division (Cornell) Bellevue Hospital.

FIG 1(a)

FIG 1(b)

FIG 2(a)

FIG 2(b)

Figs 2(a) and 2(b) E H, preoperative photographs showing typical malformation of head and prognathous jaw Proptosis of eyes least marked in this case

sagittal sutures, pressure downward into the middle fossa, and pressure forward, causing protrusion of the eyeballs due to shallow orbits. The convolutional markings are unusually prominent due to increased intracranial pressure.

"This will eventually result in blindness due to

papilledema and a secondary optic atrophy and may probably result in idiocy unless the condition is corrected surgically."

On the day before operation a blood transfusion of 200 cc was given. The day of operation, October 22, 1940, his head was shaved and it

showed a most peculiar formation (Figs 2(a) and 2(b)) There was an apical bulging at the site of the anterior fontanel which protruded $1\frac{1}{2}$ inches or more above the level of the narrowed skull like a haystack. With the head shaved, the prognathous jaw was accentuated in appearance.

The operation as previously advocated was carried out but in this case in one stage. A midline incision, extending from the hairline on the forehead directly backward, bifurcating and extending for a distance of about $1\frac{1}{2}$ inches just above the external occipital protuberance, was made. All of the soft parts, including the pericranium, were stripped off the skull and reflected downward over the ears. This afforded proper exposure of the entire vault of the skull. The skull was cut in variously shaped and sized pieces. It was necessary to cut that portion of the skull forming the marked protuberance in smaller pieces in order to have them conform properly.

During the procedure the same phenomena—i.e., bulging of the dura between the partially cut pieces of bone, pulsation of a bone flap, etc.—were observed. Upon completion of the operation one could readily perceive that the proper shape of the skull had been restored and that the eyes were less prominent (Fig 3).

A protective dressing was applied. The incision healed kindly. A radiographic report on November 1, 1940—ten days following operation—reads as follows:

"Films made of the skull in the anteroposterior, and posteroanterior and both lateral directions (Figs. 4(a) and 4(b)) show that approximately seventeen holes, 1 cm in diameter, have been drilled through the upper portion of the frontal and both parietal bones. The bone has been cut between these holes leaving a checker-

Fig 3 E H, photograph made on the table immediately following operation

board appearance in the upper half of the cranial vault. The separation between the rectangular fragments varies between 1 to 4 mm. The deformity of the upper and anterior portion of the cranial vault which was apparent on the original films has completely disappeared."

There was noted the same semisolid sensation on palpation of the skull observed in Case 1. The sections of the skull became fixed rather rapidly. When he was discharged on November 19, 1940, the vertex offered rather firm resistance on pressure. Complete filling in of the intervals between and fixation of the pieces of bone can be expected. The operation was performed in this

Fig 4(a)

Fig 4(b)

Figs 4(a) and 4(b) E H, x-ray films of skull made on tenth postoperative day

case to prevent blindness and mental deterioration.

Case 3—In February, 1940, Dr Barnes Woodhall, professor of neurosurgery at Duke University, wrote to me as follows

"Some time ago Dr Deryl Hart gave me a reprint published by you in the *Archives of Neurology and Psychiatry*, December, 1938, on the subject of oxycephaly, describing your new procedure for its relief. I had been treating these children with and on my own service here with bilateral decompression and naturally had never been fully satisfied with our results.

"I was much impressed with your new procedure, and I am taking the liberty of forwarding to you some photographs and x-rays of a case in which it has been applied. In this child the intracranial pressure was terrific and, as you will see in the x-rays, the right side expanded a great deal following morsellation. When the left side was done at a later date the expansion was not so marked. However, the clinical result except for the slight asymmetry is splendid. The child's vision has improved, the exophthalmos has decreased, and the child has become very alert and, according to its mother, completely transformed.

I have several more patients in whom I should like to try this procedure, and I should greatly appreciate any criticism you may have from your experience."

Dr Woodhall sent photographs and x-rays of this patient, but did not send the clinical record, therefore, the case report cannot be given more completely.

Case 4 (Clinical record from Dr Barnes Woodhall)—T C, a white girl aged 14, was born with a peculiarly shaped head and protruding eyes. She was admitted to Duke Hospital June 6, 1940, with the complaint of convulsions of ten months' duration. During the convulsions there was cyanosis, unconsciousness, urinary incontinence, and a drawing up of the hands and legs. The seizures had increased in frequency and severity. When she was admitted they were occurring five and six times a night. There were marked bilateral exophthalmos and other typical features associated with oxycephaly. A prominent smooth bulge in the anterior fontanel measured about 4 or 5 cm. Optic disks were a trifle hazy, vision was 20/200 in the right eye and 20/400 in the left eye. X-ray films of the skull showed a typical picture of oxycephaly with decided convolutional markings and absence of suture lines. The sella were small and deep.

Lumbar puncture revealed 240 mm water spinal fluid pressure. Encephalograms showed typical small ventricles without loss of symmetry. The blood and spinal fluid Wassermann and Kahn tests were negative. Electroencephalograms showed the presence of delta waves over the entire cortex, indicative of diffuse increased intracranial pressure. She was

discharged to return when hospital arrangements could be made.

The patient was readmitted in November, 1940. A complete examination from all angles was made, including endocrine consultations, audiograms, electroencephalograms, Binet's test, etc—too detailed to report here. The exophthalmos had increased enormously from November 5 until the time of the operation in the middle of November. The typical operation was done on the right side by Dr Woodhall, to be followed by a second stage on the left side at a later date. She made a good recovery. Comparison of the photographs before and after the first procedure showed marked recession of the bilateral exophthalmos. Vision, which had gradually become less between the time of the first examination and operation, improved. Electroencephalograms showed improvement.

Other Cases—I have reports of 3 cases operated upon by Dr R F Slaughter, professor of neurosurgery at the University of Georgia, in which he stated that improvement followed operation in each case. All had rather high initial pressure on lumbar puncture, ranging from 250 to 300. All had exophthalmos and some of them had optic atrophy. All were quite dull and lethargic before operation and had the typical bulging of the dura between the cut margins of bone at operation. In his third case only one side has been operated upon.

Sufficient evidence is presented to warrant the use of this operation in cases of true oxycephaly. It is advised that the operation be done before failing vision occurs.

Summary

1 Oxycephaly, including various skull deformities, can be relieved, loss of vision can be prevented, and mental acuity can be improved or restored by the operation that has been described.

2 A follow-up of the original case showing restoration of vision and mental and physical activities is given.

3 Reports of other cases with immediate improvement are made.

4 The procedure is *not* advocated in cases of microcephaly or idiots.

5 Good results should follow performance of this operation in cases of *true* oxycephaly.

140 East 54th Street

Discussion

Dr Fred W Geib, Rochester, New York—Dr King has made a great contribution for the relief of increased intracranial pressure in oxycephaly by inventing the mosaic craniotomy. Apparently in vigorous patients it can be done

in one stage, although it may be a bit safer to follow his two-stage technic. Certainly before Dr. King gave us this operation, we were discouraged with the results of operating on these cases.

Faber and Towne, in reporting "Early Craniotomy as a Preventive Measure in Oxycephaly and Allied Conditions with Special Reference to Prevention of Blindness," say that the symptoms of vomiting and headaches do not play an outstanding role because the intracranial pressure hardly ever attains a considerable degree. This means we are dealing with a slow insidious process that should be recognized much earlier. The ophthalmologists usually see these patients first because of failing vision. The youngest patient mentioned in Dr. King's series, I believe, is 5 years of age. Faber reported operating on a patient 6 months old on whom he did a linear craniectomy. I operated on a child 21 months old who had early fusion of the sutures, but the anterior fontanel was open and bulged out, giving a unicorn appearance. Knowing we could not do a mosaic craniotomy because we would be unable to suture the scalp

together, we tried a cross craniectomy on one side. The incisions through the scalp were stopped near the center of the cross to prevent a four-cornered closure and to help hold the scalp together with some intact blood supply. The child did well, although the flaps were under tremendous pressure. In the intervening two months he began to walk, his speech became clearer and his vocabulary increased, his exophthalmos decreased, fretfulness and holding his head disappeared, and there was a rounded contour of the skull on the operative side. We did the same procedure on the opposite side and lost him a few hours later from herniation into the foramen magnum. I mention my experience with this early type of case because of the tremendous increase of intracranial pressure which is not seen in the older cases. It seems reasonable to suppose that the extra capacity attained by doing the mosaic craniotomy is enough to alleviate the disproportion between a growing brain and a stationary skull in older patients, but in younger patients I wonder if we will not have to do further skull expanding operations after several years have elapsed.

PUBLIC BECOMING AWARE OF ADVANTAGES OF ETHICAL, PRESCRIBED REMEDIES

"Education is making the public aware of the advantage of using ethical remedies and prescribed remedies," the *Journal of the American Medical Association* for June 21 declares in commenting on the results of recent federal legislation affecting prescriptions and "patent medicine" claims.

"When the new Federal Food, Drug and Cosmetic Act was enacted," the *Journal* says, "many doubted its effectiveness. Similar consideration was given to the Wheeler-Lea Amendment to the Federal Trade Commission Act, which became a law at about the same time. Now some figures have become available which seem to indicate clearly that such legislation is having a desirable effect. The *American Journal of Pharmacy* for January, 1941, contains an item under the title 'The Nation Takes Its Medicine,' noting that prescription drugs and medicines showed an increase of \$36,000,000 for 1939 over 1937 and that 'patent' and proprietary medicines for public sale decreased \$18,000,000 in

value in the same period. The actual value of the prescription medicines in 1939 was \$178,930,487. The value of 'over-the-counter' medicines in that year was \$166,577,263. Obviously, therefore, the permissible claims for 'patent medicines' today are so restricted as to reduce their sale to the public, or the public is becoming better informed as to the advantages of employing ethical remedies and prescribed remedies. The *Drug and Cosmetic Industry* for December, 1940, provides an analysis in its story 'Ethicals Take Lead.' Apparently vitamins showed the greatest gain, glandular preparations also advanced, and the use of biologic preparations was adversely affected by the popularity of sulfanilamide in infectious conditions. If, by action of the various federal agencies, the sales of 'patent medicines' continue to decrease, a new day will dawn for the health of the American people.

"The health of the nation is an integral part of national defense."

NINETY-TWO AMERICAN DOCTORS HAVE QUALIFIED FOR SERVICE IN GREAT BRITAIN

A total of 230 applications, up to September 4, have been received by the American Red Cross from physicians wishing to enroll with the Royal Army Medical Corps in response to a British Red Cross request for American physicians, the J.A.M.A. for September 13 reports.

"Of these," the *Journal* says, "138 had been found unqualified because of age, lack of citizenship, or other similar reasons. Ninety-two have been qualified and 42 have been given passports to Great Britain, the remaining 50 are in process."

THE CHEMOTHERAPY OF PYOGENIC MENINGITIS WITH THE SULFONAMIDES

WILLARD B WEARY, M D , and JOHN J A LYONS, M D , Albany, New York

CHEMOTHERAPY with the sulfonamide drugs has significantly reduced the mortality rate in all types of pyogenic meningitis. The purpose of the present study is to present the results of treatment of staphylococcus (aureus and albus), Streptococcus hemolyticus, pneumococcus, and meningococcus meningitis. The material is based upon the treatment of 20 cases of meningitis and upon a review of the recent literature. Certain pitfalls in the chemotherapy of meningitis are emphasized. Observations concerning cerebrospinal fluid drainage and the subcutaneous administration of the sulfonamide drugs are presented.

Staphylococcus meningitis, though relatively rare, has been practically 100 per cent fatal until recent months. Experimental evidence concerning the bacteriostatic effect of sulfathiazole on the staphylococcus indicates that it is the most effective of the sulfonamide group.¹ Long states that sulfathiazole is the drug of choice in the treatment of all types of staphylococcal infections with the exception of meningitis.² This exception is based upon observations that sulfathiazole does not readily pass into the cerebrospinal fluid.³ On the other hand, Banks has reported a 21 per cent mortality in sulfathiazole treatment of meningococcal meningitis.⁴ This implies that the drug enters the cerebrospinal fluid in sufficient quantities or that a relatively small amount may be effective. Successful treatment of 2 cases of staphylococcal meningitis with sulfathiazole has recently been reported.^{5,6}

Sulfathiazole treatment of staphylococcal meningitis was begun at the Albany Hospital in January, 1940. Previously 1 patient had died with staphylococcal meningitis, failing to respond to sulfapyridine therapy. Sulfamethylthiazole was tried in the next case, with cure. Since then 4 patients have been treated with sulfathiazole with 1 death. In these cases an attempt was made to maintain the free sulfathiazole in the blood

at 4 to 5 mg per hundred cubic centimeters. Free sulfathiazole in the cerebrospinal fluid may reach 40 per cent of that in the blood. No values were obtained in the spinal fluid higher than 3 mg per hundred cubic centimeters. This level may be obtained by an initial oral dose of 4 Gm, followed by 4 Gm in four hours and 1 to 2 Gm every four hours thereafter.

The following case suggests that cerebral edema may be caused by drug toxicity. It also emphasizes the difficulty that may be encountered when treating meningitis in distinguishing between reactions due to progress of the disease and those due to chemotherapy.

Case Report

Case 1—A white truck driver, aged 19, was admitted to the hospital complaining of progressive loss of vision and photophobia of three months' duration. A diagnosis of a right middle fossa neoplasm was made on the basis of choked disks, visual field changes, and x-ray findings. A right temporal craniotomy was performed, and a meningioma filling the right middle fossa was removed.

Within four hours postoperatively the patient was conscious and cooperative. Periods of restlessness, drowsiness, and increasing tension of the wound necessitated ventricular aspirations of cerebrospinal fluid three to four times a day for four days. Twenty to thirty cubic centimeters of blood-tinged fluid were removed at each puncture. One to two aspirations were necessary daily from the fifth to the eleventh postoperative days, with the removal of 80 to 140 cc of clear, xanthochromic fluid at each puncture. On the thirteenth postoperative day the patient complained of severe headache, and on the fourteenth day his temperature rose to 103.4 F and his pulse rose to 132. He became comatose and developed cervical rigidity. His wound was tense and nonpulsating. Lumbar puncture showed a pressure of 360 mm of water. The cerebrospinal fluid was opalescent and contained 1,400 white blood cells per cubic millimeter, 85 per cent of which were polymorphonuclear leukocytes. *Staphylococcus albus* was cultured from the fluid. The white blood cell count was 29,500. Sulfathiazole was started (for dosage see Fig 1). Within twenty-four hours the patient became mentally alert and his temperature was 100.8 F. The wound flap became soft and pulsated. However, periods of drowsiness necessitated lumbar punctures twice daily for five days. The sulfathiazole level of the spinal fluid was too

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

From the Departments of Neurosurgery and Medicine of the Albany Hospital and Albany Medical College. Resident in neurosurgery and resident in medicine, respectively.

low to read on the first day, and no further determinations were made. A stitch abscess was opened on the fifteenth day and was healed in three days, a culture from this was negative. Spinal fluid culture after five days of drug administration was negative. On the eighteenth postoperative day his drowsiness was unrelieved by lumbar punctures. At the same time there was a low blood level of sulfathiazole and a slight rise in temperature. On the basis of these observations the dosage of the sulfathiazole was increased. On the twentieth day the temperature rose to 102.6 F. Drug fever was considered and the dose was decreased, the patient became more alert. Cervical rigidity and drowsiness increased on the twenty-third day, and the wound again became tense. Lumbar puncture showed no cells, but the sulfathiazole was again increased. The patient became semicomatose and, when a nodular rash appeared, the drug was stopped. Soon thereafter he became alert, the wound was soft, the temperature was normal, and the neurologic examination was negative. The patient was discharged on the thirty-seventh postoperative day.

Streptococcus hemolyticus meningitis is usually secondary to middle ear, mastoid, or sinus infections. The mortality in this form of meningitis has been reported as about 98 per cent.⁷ Fatalities have been reduced to about 50 per cent since sulfanilamide has been employed.⁷ Reports indicate that some diffi-

culty has been encountered in culturing the organism from the spinal fluid.⁸ The diagnosis often must be made solely by culture of the *Str. hemolyticus* from the primary focus and by the presence of gram-positive cocci in the spinal fluid.

At present, the consensus is that sulfanilamide is the drug of choice in the treatment of *Str. hemolyticus meningitis*. The free sulfanilamide blood level should be maintained between 10 and 15 mg per hundred cubic centimeters in order to produce an effective spinal fluid concentration of 8 to 10 mg per hundred cubic centimeters. Such levels may usually be obtained by an initial oral administration of 6 Gm. of sulfanilamide, followed by 1 to 1½ Gm every four hours.

Five patients with *Str. hemolyticus meningitis* have been treated with sulfanilamide at the Albany Hospital in the past eighteen months with 1 death. In this case the meningitis was complicated by the presence of *Bacillus proteus* in the middle ear and in the spinal fluid. The following is a report of a recovered case.

Case Report

Case 2—A white married housewife, aged 32, was admitted to the hospital in a semicomatose state of a three-day duration. The patient had been ex-

posed to scarlet fever three weeks previously. One week before admission she developed a fever, followed by a diffuse, erythematous rash. Five days before admission she complained of pain in the left ear, which drained spontaneously. Following this she grew worse. Her treatment at home had consisted of an unknown amount of sulfanilamide and antistreptococcus serum.

On admission her temperature was 103 F, pulse, 90, respirations, 20, and blood pressure, 120/55. An erythematous rash was present over the back and the shoulders. There was moderate tenderness over the left mastoid area. The left external auditory canal was filled with seropurulent discharge. Neurologic examination revealed marked cervical rigidity and definite right facial weakness of central type. The abdominal, knee, and ankle reflexes were absent, there were bilateral Kernig and Babinski signs. The hemoglobin was 75 per cent, and the blood leukocyte count was 21,600. A culture from the left ear disclosed *Str. hemolyticus*. On admission there was 14 mg. per hundred cubic centimeters of free sulfanilamide in the blood. A lumbar puncture revealed an initial pressure of 270 mm. of water, 405 polymorphonuclear leukocytes per cubic millimeter, and 1.8 mg. per hundred cubic centimeters of free sulfanilamide. A smear of the spinal fluid revealed a few gram-positive cocci singly and in pairs. No growth was obtained on culture.

Shortly after admission a left simple mastoidectomy was performed, with drainage of an extradural abscess from which *Str. hemolyticus* was isolated. Sulfanilamide was administered through a duodenal tube every four hours (for dosage see Fig. 2). Lumbar punctures were performed daily, with the drainage of 10 to 20 cc. each time. The patient slowly improved, and her temperature was normal on the seventh hospital day. Two days later, cervical rigidity was ab-

sent, but a left horizontal nystagmus, left Babinski sign, and clumsiness of the upper left extremity were noted. On the eleventh hospital day her temperature reached 102.4 F. There was no change in her neurologic examination. The fever was regarded as a sulfanilamide reaction, and the drug was discontinued. On the twelfth hospital day her temperature dropped to normal and remained there. The above neurologic signs, suggesting either a right frontal or a left cerebellar abscess, persisted. Since these signs slowly disappeared, they were regarded as evidence of a localized encephalitis rather than an indication of an abscess formation. A secondary closure of the mastoid wound was performed on the forty-second hospital day, and the patient's progress from then on was uneventful.

Pneumococcus meningitis is regarded as the most lethal form of pyogenic meningitis. Before the sulfonamide drugs were used the mortality was almost 100 per cent.⁹ Mortality rates from 50 to 85 per cent have been reported following the use of sulfapyridine.^{8,10,11,12} There is no doubt that sulfapyridine is the drug of choice in this form of meningitis. The concomitant use of type-specific antipneumococcus serum is advised.¹² Its use should be restricted to the intravenous route. Intrathecal administration of serum is contraindicated because of the development of subarachnoidal block, abscess, and arachnoiditis, with its consequent intractable pain, or sudden death.¹²

Sulfapyridine is present in the cerebrospinal fluid shortly after appearing in the blood and attains a level of 60 to 70 per cent of that in the blood.⁹ A concentration of free sulfapyridine in the blood should be established at about 10 mg. per hundred cubic centimeters in treating pneumococcus meningitis. This blood level may usually be maintained by 3 Gm. of sulfapyridine as an initial oral dose, followed by another 3 Gm. in four hours and the administration of 1 to 2 Gm. every four hours thereafter.

In the past year 4 patients with pneumococcus meningitis have been treated at the Albany Hospital. Two patients with type III pneumococcus meningitis failed to survive, whereas two others (type VI and type XXXI) recovered. In addition to sulfapyridine, antipneumococcus serum was given to the patients with types III and XXXI. In the following case, type VI, serum was not administered.

Case Report

Case 3—A man aged 42 was admitted to the hospital thirty-four hours after an automobile

Only 5 cases of meningococcic meningitis have been treated at Albany Hospital in the past two years. Two patients died, 1 was complicated by the presence of lupus erythematosus disseminatus and the other by a brain abscess.

Discussion

The latest reports, particularly those emanating from England, indicate that after the first diagnostic puncture no further cerebrospinal fluid drainage is needed in chemotherapy of meningitis.^{4,16} The maintenance of cerebrospinal fluid drainage was apparently of definite therapeutic value in the cases treated at the Albany Hospital. This observation concurs with that of others.^{10,12,14} Carefully controlled cerebrospinal fluid drainage is a widely used method for combating cerebral edema. The method should have application in treating the cerebral edema of meningitis. It is believed by some that this procedure also removes inflammatory products in helpful quantities and that the re-establishment of normal blood and cerebrospinal fluid circulation is promoted. There is the possibility that the periodic removal of cerebrospinal fluid facilitates the transfer of the sulfonamides through the choroid plexus. The observed increase of the sulfonamides in the cerebrospinal fluid after drainage and the subsequent clinical improvement of some of the patients in this series suggest the value of maintaining a relatively normal level of intracranial pressure by lumbar punctures or wound tapings.

The established principle of surgical drainage of primary or secondary foci is imperative in the treatment of meningitis.¹³ Sulfonamide therapy is merely bacteriostatic, not bacteriocidal.

In certain cases of meningitis the comatose condition of the patient makes parenteral administration of one of the sulfonamide group desirable.^{17,21} Repeated intravenous use of these drugs is dangerous, and severe reactions may occur because of a sudden development of an excess in the blood.¹⁸ Death in 1 case reported in this series was apparently due to the repeated intravenous administration of sulfathiazole. At the Albany Hospital the subcutaneous route is used for the administration of an 0.8 per cent aqueous solution of sulfanilamide and a 0.5 per cent aqueous solution of sodium sulfathiazole or of sodium sulfapyridine. No local tissue reactions have been noted in over 250 injections in 40 patients. Following an initial dose of 100 cc of 5 per cent sodium sulfathiazole or sodium sulfa-

pyridine intravenously, an adequate blood level may be maintained by the subcutaneous claysis of 1,000 cc of 0.5 per cent sodium sulfathiazole or sodium sulfapyridine over a period of twelve hours. This rate of administration may be continued for several days. To prevent exacerbations and complications, the drug should be continued for at least two weeks after clinical improvement has been established. Objections to the intrathecal use of the sodium salts of the sulfonamides are the same as those for the intrathecal use of serums.

The toxic manifestations of sulfonamide drugs affecting the nervous system have been regarded as of minor importance.¹⁹ Nausea, vomiting, confusion, restlessness, dizziness, irritability, lassitude, hallucinations, and neuritis have been reported. In addition, we have seen 1 case of the Guillain-Barré type of polyneuritis following the use of sulfathiazole. The nervous system complications deserve more consideration in the treatment of meningitis than in other forms of infection. Apparently, cerebral symptoms due to increased intracranial pressure may result from the toxic reaction to the sulfonamide drugs. In over 20 patients under sulfonamide therapy, an increase in the cerebrospinal fluid pressure has been observed in association with drowsiness, confusion, and even coma. In these instances, when the drug had been discontinued and fluids had been forced intravenously, the cerebrospinal fluid pressure decreased and the mental symptoms disappeared in four to eight hours. Although difficult, it is essential to differentiate cerebral edema and the other neurologic manifestations from failure of therapy or the formation of a brain or spinal abscess. This is particularly true when a febrile reaction is present. The solution of the problem can only be made by frequent observations of the blood level of the drug, daily determinations of cerebrospinal fluid pressure and cytology, and repeated neurologic examinations.

Summary

1. An analysis of the data from 20 cases of pyogenic meningitis treated with the sulfonamides is presented. Thirteen recoveries and 7 deaths resulted.

2. Sulfathiazole is suggested as the drug of choice in treating staphylococcic meningitis, on the basis of 4 recoveries in 5 cases.

3. The value of cerebrospinal fluid drainage as part of the treatment of meningitis is stressed.

4. Successful subcutaneous administration

of a 0.5 per cent aqueous solution of sodium sulfathiazole or sodium sulfapyridine is noted

5 Cerebral edema and the Guillain-Barré type of polyneuritis are presented as possible toxic manifestations of the sulfonamide drugs

6 The differentiation between toxic neurologic manifestations due to the sulfonamides and failure of therapy is of major importance in treating meningitis

The grateful thanks of the authors are extended to Dr T J C von Storch for his valuable help and criticism

Discussion

Dr Emanuel Appelbaum, *New York City*—It is a privilege to discuss this excellent paper by Drs Weary and Lyons

In an extensive experience over a period of many years, the Meningitis Division of the New York City Health Department has had a mortality rate of 18 to 25 per cent in meningococcal meningitis treated with serum. Except in the septicemic type of case we have used the serum intraspinally only. With the introduction of sulfonamides we have not given serum intravenously even to the septic cases. There can be no doubt that the sulfonamides are of great value in treating this form of meningitis. There have appeared several favorable reports on the use of sulfonamides alone in this disease. Indeed, in a small group of cases I have obtained excellent results from either sulfanilamide or sulfapyridine without the use of serum. However, the endemic form of the disease varies so greatly in

virulence that only an outbreak of epidemic proportions would make it possible to evaluate the question of sulfonamides alone versus the combined treatment with sulfonamides and serum. I should like to point out also that we have found sulfapyridine at least as effective as sulfanilamide in this disease.

In pneumococcal meningitis we have had a recovery rate of about 33 per cent with sulfapyridine and sodium sulfapyridine. The sulfapyridine was given orally and, in several instances, rectally in the form of an emulsion. One may obtain adequate blood and spinal fluid levels of the drug following rectal administration. The sodium sulfapyridine was given by vein in solutions varying from 0.8 to 5 per cent and was of particular value in the comatose cases. In many instances we have injected a 1 or 2 per cent solution of this compound intraspinally without any untoward reactions. In most of our cases specific serum was also injected intrathecally, usually combined with the sodium sulfapyridine. However, many of our recoveries followed the use of sulfapyridine alone. At present, we are trying to evaluate the respective merits of sulfapyridine alone and its combined treatment with serum. In some of our recent cases, when the patient failed to respond to sulfapyridine, we changed to sulfadiazine, often with excellent results. This new sulfonamide compound is unquestionably effective against the pneumococcus and other organisms and is probably the least toxic of all the sulfonamides. I am in full accord with Dr Weary and Dr Lyons in stressing the importance of changing sulfonamides when there is a failure of therapeutic response.

In meningitis due to the hemolytic streptococcus we have had 85 per cent recoveries following sulfonamide therapy. Most of our patients were treated with sulfanilamide, but a significant number of recoveries followed the use of neoprontol or sulfapyridine. While it is probably desirable to obtain drug levels of 10 or more milligrams per hundred cubic centimeters in the blood and 6 or more milligrams in the spinal fluid, it should be noted, nevertheless, that there is no evidence of any correlation between drug level and recovery.

We have seen successful results in staphylococcal meningitis treated with sulfathiazole. However, it is my belief that sulfapyridine is the drug of choice in this disease, since sulfathiazole does not readily pass into the spinal fluid.

Since there has occurred in recent years a rise in the incidence of meningitis due to *Hemophilus influenzae*, it is important to comment briefly on the treatment of this disease. We have had about 50 per cent recoveries with sulfapyridine and sodium sulfapyridine. Many of the patients also received the specific horse serum intraspinally. However, a significant number of recoveries followed the use of sulfapyridine alone. Two patients who failed to improve with sulfapyridine responded promptly to sulfadiazine. Excellent

results have been claimed also for a special rabbit serum.

I am in complete agreement with Dr Weary and Dr Lyons with regard to the therapeutic value of spinal fluid drainage and the importance of eradicating foci of infection. In this connection it should be noted that a mastoiditis may not present clinical, or even x-ray, evidence of involvement.

With regard to drug fever, I have observed two types. One form of fever occurs relatively early in the course of the disease when, after a short period of obvious improvement, the temperature begins to rise in steplike fashion. More common is the delayed drug fever that occurs late in the course of treatment. It is at times difficult to decide whether the fever is due to the infection or to the drug.

Dr Weary and Dr Lyons have stressed the sulfonamide toxic manifestations affecting the nervous system. In addition to the reactions enumerated by them, we have seen also a number of patients who developed various psychoses. While these toxic reactions are not infrequent, as a rule they are not serious.

Dr H. van Zile Hyde, *Albany, New York*—The present generation of younger doctors has become callous to miracles. Despite this fact, the presentation of 5 cases of staphylococcal meningitis with only 1 death is breathtaking. In recent years we have adjusted our thinking to accommodate the acceptance of recoveries in cases of hemolytic streptococcal meningitis, but we had come to think that the staphylococcus was, for the time being at least, unbeatable. We noted reports of recoveries by Dietel and Kaiser and by Sadusk and Nielsen but, in our thinking, catalogued them unfairly with the isolated reports of recoveries in all types of pyogenic meningitis which have occurred in the literature from time to time in the past, with recovery always attributed to some different and often bizarre method of treatment. When we consider the results obtained by Drs Weary and Lyons, reported here, and group these with cases we have seen or have been told about by our colleagues, we must accept the fact that staphylococcal meningitis is now one of those diseases that pose a real challenge to the physician, demanding his utmost attention to every detail of therapy.

Drs Weary and Lyons have added important factual material to one particular discussion of vital importance which has, heretofore, been centered chiefly around theoretic considerations. In balancing the relative bacteriostatic efficacy of sulfapyridine and sulfathiazole against the poorer penetration of the latter through the blood spinal fluid barrier, it has been more or less generally agreed that sulfapyridine was the drug of choice in staphylococcal and pneumococcal meningitis. Certainly, the evidence presented here, despite any theoretic considerations to the contrary, demonstrates that sulfathiazole is a remarkably

effective drug in at least the staphylococcal group. This is particularly encouraging because, from the standpoint of annoying toxic reactions, it is the more satisfactory drug to employ.

This paper is an important contribution to a field that has been one of the most discouraging in the practice of medicine. I am sure, however, that the authors would be the first to admit that it is not the last word. In sharp contrast to the history of arsenic agents in the treatment of syphilis, new and more effective sulfonamides are appearing at a rapid pace, tending to supplant their predecessors. The medical world now has its eyes focused on the possibilities of sulfadiazine. Reports are sparse as yet, but there is promising evidence of greatly lowered toxicity, better absorption, slower excretion, diminished acetylation, and increased bacteriostatic efficacy covering a wide range of bacteria. Preliminary evidence also indicates that it penetrates the blood spinal fluid barrier about as well as sulfapyridine. The evidence thus far is scant but indicates an even brighter future than is anticipated in this paper. It behooves us all to keep a close eye on the literature regarding sulfadiazine so that we may be prepared to employ it intelligently upon its release for general distribution.

Dr Weary and Dr Lyons are to be congratulated on the diligence with which they observed and treated their patients. To be noted particularly is their close attention to detail and their adaptability to the changing condition of the patient. The drug was carefully administered with constant observation of its effect in relation to toxic potentialities and the status of infection. Coupled with this was the courage to withdraw or readminister as the condition indicated. Blood levels, spinal fluid levels, fluid requirements, urinary findings, spinal fluid pressures and cytology, and localization of infection were all carefully watched and skillfully interpreted and handled. A successful outcome should not be attributed alone to the sulfonamides but must be attributed to the care and intelligence with which these drugs were administered. Pyogenic meningitis still requires skillful care—medical and surgical.

Dr George V. Taplin, *Rochester, New York*—Drs Weary and Lyons are to be congratulated on their excellent paper. Their results are far superior to those obtained in Rochester, particularly in reference to pneumococcal meningitis. For the past two years I know of only 3 recoveries in 25 or 30 cases of pneumococcal meningitis. Two of these cases were secondary to mastoiditis, the third case was an infant with primary meningitis. The infant made a recovery following the use of sulfapyridine alone.

Inasmuch as nearly everyone has used the same therapeutic agents for these diseases, the results of Drs Weary and Lyons must in large part be attributed to the intelligent handling of their cases. I was particularly interested in the

use of the sodium salts of sulfapyridine and sulfathiazole by hypodermoclysis. It has not been appreciated generally that it is possible to use these drugs in this manner. In fact, the various drug houses warn against such a mode of administration, stating that serious local reactions may result. At Rochester we have used sodium salts of sulfapyridine, sulfathiazole, and sulfadiazine in this manner in over 150 cases and have not observed a single local reaction. We feel that the subcutaneous route of administration is preferable in most cases of meningitis where parenteral therapy is needed because a more constant, satisfactory blood concentration of these drugs may be attained. The blood concentration is maintained for longer periods of

time than with intravenous administration, and there is less danger from untoward renal reactions.

As a result of our preliminary experience with about 25 cases of pneumonia treated with sulfadiazine, we feel that this drug is likely to replace all the previously used sulfonamides, particularly in pneumococcal and staphylococcal infections.

Apparently, sulfadiazine is at least as effective for staphylococcal infections as sulfathiazole. However, in staphylococcal meningitis it should be superior because it penetrates the spinal fluid to a high degree. For the same reason, it should be superior to sulfapyridine in the treatment of pneumococcal meningitis.

GROWING DEMAND FOR INDUSTRIAL PHYSICIANS

"The demand for more and better trained medical personnel in war industries, under both governmental and private control, is steadily becoming more insistent," the *Journal of the American Medical Association* says in an editorial on "Availability of Trained Industrial Physicians," in its March 29 issue.

"The scarcity of competent industrial nurses, engineers and physicians accords with an early impression of the Committee on Medical Preparedness of the American Medical Association, one of the first resolutions of the committee called for prompt organization and adequate support of training facilities for physicians interested in this field."

"The present emergency will undoubtedly be sufficient inducement for many more physicians to undertake industrial medical service, especially those who have an interest in preventive medicine and a flair for administration. There are sound indications for believing that interest in industrial medicine and hygiene will not lapse as it did in the period following the last war. Opportunity for professional advancement, then, is most reassuring and need not be considered as limited to the period of the emergency. Certainly the obligation of medical educators to prepare the profession for greater and more competent participation in the maintenance of health in industry is much better recognized. At present, organized instruction is available in a few medical and professional

schools. Teaching facilities of the same type ought to be widespread and will be developed elsewhere without much difficulty as soon as financial support becomes available. The fundamentals of preventive industrial medicine and surgery can be supplied to a well qualified physician in three months' time, especially if a period of controlled experience in an acceptable industrial medical department can be added to this instruction. Since the medical requirements of industry are so varied, considerable adaptability in the content of the course and in field work is essential. Medical societies are also developing introductory and refresher courses as part of the program to integrate all industrial medical activity under the joint guidance of the committees on industrial health in the state medical societies and the bureaus of industrial hygiene in the state governments.

"The Subcommittee on Industrial Health and Medicine of the Federal Security Agency, acting as coordinator in this field, has developed a Committee on Registration and Training of Medical Personnel for Service in Industry. During the early period of adjustment to emergency conditions, physicians who wish to apply for intensive training or for actual placement in industry are urged to register their names with the office of the Council on Industrial Health of the American Medical Association, 535 North Dearborn Street Chicago."

Symposium on Health Education for Youth Organizations

A HEALTH PROGRAM FOR YOUTH ORGANIZATIONS

J G FRED HISS, M D , Syracuse, New York

TODAY practically all American youth organizations have health programs of various kinds. These vary from a few lessons in first aid to a fairly comprehensive program. Some of these consist of, or include, a physical examination or inspection before the member is allowed to participate in athletics or go to a summer camp. Forms for such examinations vary in size from a small card to several full-sized sheets of paper. In addition, practically every public school in the state has some kind of a periodic medical examination of all pupils. These examinations are more properly called medical inspections and serve the chief purpose of detecting communicable diseases. Comparatively few pupils ever receive a complete or adequate examination during their entire school career.

Nation-wide experiences with the Selective Service examinations of men between the ages of 21 and 36 have again confirmed what most investigators have long known—namely, that the incidence of preventable and correctable defects is high. The most frequent causes of rejection because of physical condition are defects of teeth, eyes, feet, ears and disturbances of height and weight. Because the findings are similar to those of the first World War Draft, one can probably assume that youth health programs are inadequate or involve too small a percentage of the total population. The large number of rejections has caused much comment in newspapers and periodicals. Several remedies for this state of affairs have been proposed including a congressional appropriation of \$150,000,000 for a nation-wide plan of physical education and training with the implication that such a program would be a powerful factor in improving the health of the nation. It would seem that this is an opportune time for the organized medical profession to study this problem and to aid in its solution.

It has been my privilege and pleasure to be associated with the New York State 4-H Clubs for several years. This state has 31,000

of the 1,400,000 4-H members in the entire United States. Most of the members are boys and girls between the ages of 10 and 21 residing on farms or in small rural communities. I feel that this organization has gradually evolved a commendable health program. It is largely because of this contact and its resulting experience that I am suggesting the following program for use by the various youth organizations of this state. Possibly it might be sounder to have the State Educational System follow such a health program, since it would then reach all the youth of the state rather than only the fraction that belongs to youth organizations. However, it seems infinitely easier to work out many of the various aspects of this problem on smaller and more compactly organized groups such as 4-H Clubs, Boy Scouts, Girl Scouts, and others.

Before proceeding with the plan let me say plainly that I am making no claim for originating any of the 4-H Health Program. Some of it—for example, the nutrition part—was not even planned by the medical profession but was developed by the Nutrition Department of Cornell University. Because of its excellence it is a pleasure to endorse it.

The proposed plan consists of three parts, partially overlapping: (I) Health Education, (II) Health Preservation, and (III) Health Restoration.

Under Health Education the plan calls for the dissemination of information dealing with all health aspects of life. The detail with which this is done naturally must vary with the age group under consideration, but in general the following subdivisions can be made.

Foremost, it seems essential to broadcast a great deal of general information about nutrition. The great use of the many recent discoveries in this field should be primarily for the prevention of illness and only secondarily by physicians for the cure of illness. It is becoming more and more apparent that the tremendous number of dental defects in the general population is due largely to faulty

nutrition Preventive dentistry is a subject really in its infancy Adequate nutrition is also the basis for good general health and a normal development of the body 4-H Club members already know many basic facts of nutrition because they have been forced to learn them in connection with the care of their livestock, and it is rather easy for them to see the rationale of applying these same factors to themselves

The second big subject under the heading of Health Education might be called Personal and Mental Hygiene These terms are self-explanatory

Thirdly, under Health Education, it is necessary to describe the ordinary communicable diseases in some detail This applies especially to the modes of transmission so that an enlightened public may aid local health officers in preventing and combating epidemics of various kinds Without such help public officials can accomplish little

Next, it is essential that considerable information concerning first aid be given to the general population, because it is practically always members of the laity who first see an injured or sick person Many lives are lost annually because of inadequate or improper first aid given by well-intentioned friends In connection with this subject it is necessary to give rather technical information in some fields—for example, persons injured in an automobile accident who cannot move their extremities should be left where they are because they may have a fractured spine or neck and, again, persons who have an abdominal pain should not be given cathartics because they may have appendicitis, etc There are many conditions in which it is impossible to reduce the death rate unless the public is told about these conditions and advised what to do and what not to do about them As examples of the successful dissemination of life-saving information, one might cite, first, the widespread knowledge regarding the care of fresh wounds and the prevention of their contamination and, second, the understanding of the procedure of artificial respiration

There are many other subjects that can be covered in a general health education program, I have mentioned only four of the most important

The second part of the program deals with Health Preservation and can be subdivided at once into general and specific measures Under general measures comes, first, the application of information gathered through the

health education program, such as using one's knowledge of nutrition and personal and mental hygiene

It is under the heading of personal hygiene that one should consider, among other things, good posture, systematic exercise, and both indoor and outdoor recreation. Important as these things are, they in themselves cannot constitute a complete health program

Application of the knowledge of communicable diseases should be used to provide a safe milk supply, a safe water supply, and the abatement of fly and other insect nuisances The knowledge of the common causes of accidents should be used to prevent them.

Under the group of specific measures for health preservation, two are generally advocated antismallpox vaccination and immunization against diphtheria Others, such as typhoid immunization, should be used when indicated or requested by local health officers

The third part of the program deals with Health Restoration or the detection and correction of defects To do this adequately calls for physical and dental examinations at least once a year This part of the program must be carried out in its entirety by physicians and dentists The ideal arrangement is to have such examinations carried out on a private patient-private physician basis. In this way the patient will be considered as an individual rather than merely a collection of organs with a serial number Such a program imposes a definite obligation on the part of the physician to render a good complete examination It also calls for some standardization of procedures At this point I should like to suggest that the *Manual for Physicians* published by the American Medical Association entitled "Periodic Health Examination" be used as a basis. If this is done, then an identical physical examination blank can be used by all comparable youth organizations and probably also by the state school system In this way multiple examinations can be avoided In this connection I should like to quote verbatim a sentence from the *Manual* as indicating a goal to which such a program should be directed

"The ideal conception of the periodic health examination is that it is done in the interest of the patient and that the records thereof remain in the confidential files of the personal physician, just as do the records of consultations with patients for purposes of diagnosis and treatment in illness."

Sometimes, especially at the beginning of this program of annual examinations, it may be advisable, as a temporary expedient only, for county societies to make such examinations on an organization basis. Such a project has just recently been carried out by the Delaware County Medical Society, and their results and experiences form the subject of the following papers in this symposium. It is probable that similar projects will be attempted in two additional counties this year. Quite naturally, all arrangements for these examinations should be made by the medical societies of the counties affected.

As an aid to this campaign of annual physical examinations of 4-H Club members, several educational features are planned and should be mentioned at this point. At the Annual Congress of about 1,500 members held in Ithaca during the first week in July, 1941, actual physical examination demonstrations, one for the boys and another for the girls, were given. It is felt that such demonstrations make the members more physical examination-minded and greatly increase the numbers who will request this service of their family physician. Also, by becoming familiar with the procedure, much of the nervousness and shyness attending the examination of

boys and girls for the first time should be eliminated. It was found that it was quite a surprise to some members to learn that they had to remove their clothing for the examination. "We never had to do this for a school examination" was a frequent comment. It was also planned to make either a moving picture film or a set of kodaslides of this same demonstration to be shown at various 4-H Club meetings throughout the state.

This entire plan can be a success only if the entire organized medical profession supports it. A strong plea is therefore made that each county medical society cooperate actively with the leaders of the various youth organizations in its area. In the sparsely settled counties the entire society can function in this capacity, while in the more populous counties a special committee appointed for this purpose might function more efficiently.

I suppose that it will be said that any comprehensive plan like this one will be accused of promoting self-medication and of making neurotics, but I am personally sure that if the doctors will aid and guide this plan in their own localities this risk will be entirely eliminated.

"Good national health is the most fundamental of all defense measures."

DEMONSTRATION OF A COUNTY 4-H CLUB HEALTH PROGRAM

EVELYN F H ROGERS, M D, Oneonta, New York

THAT 4-H Clubs are interested in the health of individual members to the extent of choosing the healthiest or most nearly perfect boy and girl in an annual contest is common knowledge. In recent years, however, prominence has been given to a more constructive health program, which seeks to promote a higher standard of health in each and every member by teaching him the basic elements of personal hygiene and good health. The demonstration to be discussed, as carried out in Delaware County in the fall of 1940, was precipitated partly by the national cry of "Better Health for Defense" and is a visible manifestation of such a trend. The program provided facilities so that every member in the clubs might receive a general physical and an orthopedic examination. Furthermore, the club leaders were to be included in an in-

tensive follow-up to stimulate interest in carrying out the ensuing recommendations.

The objective of the program was primarily educational in that it aimed to impress on these young people the value of such an examination carried out annually. Secondly, through the leaders' participation it was hoped that the ways and means might be unearthed to correct various defects previously unknown or neglected.

Considering it wise to proceed with caution in this more ambitious type of health program, the project was to be limited to the one county in the state until the end result might be determined by a series of re-examinations. This report, therefore, constitutes only an analysis of the primary examinations, sufficient time not having elapsed for their evaluation.

The project was endorsed by the state leader for 4-H Club work and the New York State Department of Health. Tentative plans were

outlined at a meeting of representatives of these organizations in April, 1940, which was also attended by a member of the Department of Education. At that time it was determined that the Orthopedic Division of the Health Department was willing to give each child an orthopedic examination and that through federal funds a small honorarium was available for the local physicians who were to be asked to examine the children. The county medical society agreed to cooperate, and 19 of its 30 members conducted the examinations.

Delaware County is a hilly rural area. The population, according to preliminary returns of the 1940 census, was 40,989, a decrease of 0.4 per cent from the 1930 census. The two largest villages are Walton and Sidney with populations between 3,000 and 4,000. Sidney is the seat of one of the major defense industries, the Scintilla Magneto Plant, but the chief industry of the county as a whole is dairying. The population is 95 per cent native white. The area in square miles is 1,449, there being, therefore, an average of 28 persons per square mile.

4-H Club work constitutes part of the extension program of all land grant colleges organized by the United States Department of Agriculture. It is a specialized educational enterprise for rural youth from 10 to 21, carried on in this state through Cornell University under the immediate supervision of a county club or extension agent. In 1940 Delaware County had the largest membership in the state, with 113 organized clubs and a total membership of 1,405, making an average of 13.6 members per club. Each club is under the guidance of a local voluntary leader and, since the number supervised by the leader is small, it seemed reasonable to expect comprehensive assistance in carrying to completion any follow-up that might prove necessary.

Arrangements were made by the county club agent to conduct the examinations in suitable centers which, for the most part, were centralized schools. Necessary supplies and transportation were provided by the county clubs. Nursing assistance at examining centers was given by the school and public health nurses in the county. Physicians were assigned by the county medical society according to the number required for any one session. A member of the staff of the Orthopedic Division of the New York State Health Department was present at most of the sessions.

A comparatively simple record form was devised for use. The identifying data, his-

tory, weight, height, temperature, and pulse were obtained and recorded by the nurse. She also obtained audiometer readings and refractive errors from the school examinations if such were available. Otherwise, she checked the hearing with a watch and the eyes by a Snellen chart. The children were suitably dressed to facilitate an adequate examination.

The general physical examination of the 1,047 club members examined in the twenty-two centers was accomplished in twenty-three days. From 1 to 4 doctors were present at one period, the total number of physician sessions being 97, making an average of 10.7 patients examined per doctor per session. Each session was from two and one-half to three hours long, so that the doctor spent about fifteen minutes on each patient. On an average, 33 patients per session were checked by the orthopedic surgeon.

Out of the total club enrollment of 1,405 members, 1,072 or 76.3 per cent were examined. A general physical examination was received by 1,047, or 74.5 per cent of the group, 10 of these being done privately by the family physician. Orthopedic examinations were made on 1,028, or 73 per cent of the children, while 1,003, or 71 per cent, received both types.

Of the total number of individuals examined, 71.4 per cent were from 10 to 14 years of age, 19.5 per cent were in the age group from 15 to 19, while only 8 per cent were in the 5 to 9 group, and 1.1 per cent were over 20.

Of the group 41.6 per cent were boys and 58.4 per cent were girls. The preponderance of girls is constant throughout the specific age groups. Only 2 of the group were colored.

Based on the population of Delaware County in 1940, estimated for specific age groups and excluding the 32 living outside the county, it was found that in the 10 to 14 age group 21.9 per cent of the estimated Delaware County population for 1940 were examined. Although these children came from the more rural areas, the county is so predominantly rural that this number may be considered a fair sample in this age group for the county as a whole. Only 2.7 per cent of the estimated population in the 5 to 9 group and 5.7 per cent in the 15 to 19 group were examined, the number over 20 being negligible.

HISTORIES

In obtaining the family history particular note was made of familial contact with tuberculosis. Only 41 such instances were found. Of this group, 16 had been x-rayed and were

PERCENTAGE OF 1047 4-H CLUB MEMBERS
REPORTING HISTORY OF RECEIVING IMMUNIZING AGENT AGAINST
SMALLPOX DIPHTHERIA AND TYPHOID FEVER

FIG 1

found to be negative, while 25 had not been followed up. There were 12 children who gave a history of a cervical adenitis that had required incision and drainage, 2 of whom were known to have had a negative x-ray. The remaining 10 in the latter group, together with the 25 in the former, making a total of 35 individuals, appeared to be the only ones in whom one might search for tuberculosis as far as the history was concerned. Only 1 child gave a past history of healed childhood type tuberculosis. The percentage of those having had measles, whooping cough, chicken pox, and mumps increased as one would expect in the older age groups.

Further histories of illness, other than operations, were not remarkable. The most common ailment, reported by 17.2 per cent, was a frequent sore throat, the individual's standard of what constituted frequency being accepted. A history of pneumonia was given by 9.3 per cent, of otitis media by 8.9 per cent, while 2.8 per cent gave a history of what might be considered a rheumatic syndrome—namely, joint pains or rheumatism, rheumatic fever, and chorea. A past history of heart disease was obtained from 5, or 0.5 per cent.

A tonsillectomy had been performed on 26 per cent of the group, this being the most

common surgery reported. This number contrasts sharply with a sampling of 1,000 11-year-old children in New York City schools, carried out by the American Child Health Association,¹ in which instance 61 per cent had had a tonsillectomy.

A history of having been vaccinated for smallpox was given by 66 per cent of the group, and 65 per cent reported having received an immunizing agent against diphtheria (Fig 1). The number claiming past immunization for typhoid, amounting to 0.8 per cent, was naturally small. No form of artificial immunization had been received by 16.8 per cent.

A dietary history was obtained primarily for educational purposes. Without a detailed quantitative and qualitative analysis over a period of time it is impossible to derive any conclusions as to the adequacy of the daily intake of food. From the data on hand, however, it was possible to ascertain those who received daily less than 1 pint of milk, 1 fruit and 1 vegetable, in addition to potato, and an egg or some meat. The 35 per cent falling in this category may be classed as having an inadequate diet. Moreover, a number of these, amounting to 10 per cent of the study group, reported drinking no milk. That this estimate of the dietary status is not grossly in error is strengthened by two facts: first, that 72 per cent of the individuals noted by the examining physician as having good nutrition received a diet containing at least the daily intake mentioned, while only 27 per cent of those on the inadequate diet were so classified. Second, only 38 per cent of those receiving this diet or better required dental care, while 52.3 per cent of those on the inadequate diet required care.

Physical Examinations

Recent studies such as that by Souther, Eliot, and Jenness² have shown the inconsistencies inherent in using any of the various indices of nutrition. For this reason the decision in regard to nutrition was left entirely up to the examining physician. In the opinion of these physicians 54 members, or 5.2 per cent of the 1,047 receiving a physical examination, were malnourished.

Of 1,006 individuals whose eyes were examined for limitation of vision, 346, or 34.4 per cent, were not normal. Of this number, 97, or 28 per cent, wore glasses. One hundred and four children, or 11 per cent of the total group, showed an error of 20/50 or worse, and 55 of these, or 53 per cent, wore glasses.

latter findings are in substantial agreement with those obtained by the American Child Health Association¹ in sampling 5,000 New York City fifth and sixth grade school children, in which instance 14 per cent had a visual defect of 20/30 or worse, one-half of whom were wearing glasses

Of those who were wearing glasses in the 4-H group, about one-third were corrected to 20/20. Assuming that until proved otherwise vision is correctable to 20/20, it was found, on adding the 59 whose glasses did not correct the error to the 249 who wore no glasses but showed a refractive error, that those needing further care amounted to 308, or 30.8 per cent of the study group

Upon otoscopic examination, 15, or 1.4 per cent, were found to have a chronic otitis media. According to the school records, 26 per cent of the group had been given an audiometer test by the group method within a year. Acuity of hearing in the remainder was checked with a watch heard normally at a distance of 20 inches from either ear. Included as having a limitation of hearing are those with a loss of 6 decibels in either ear, as well as those unable to hear the watch at less than 20 inches. By these combined methods 14.8 per cent appeared to have some impaired hearing. It is not felt that such results are accurate, because, undoubtedly, many of these would be found to have normal hearing if retested individually with an audiometer.

From the data on hand it was not possible to determine those who had received past dental care. However, the examining physicians noted that 43 per cent of those examined required dental care.

Findings on examining the tonsils indicated that in addition to the 26 per cent who had had a tonsillectomy 22 per cent had pathologically enlarged tonsils. Realizing that in such instances repeated examinations should be the dominant factor in advising a tonsillectomy, the only recommendation made was that the patient consult his family doctor regarding the desirability of this procedure.

No cases of congenital heart disease were diagnosed, while 6, amounting to 0.6 per cent of the group, were classified by the examining physician as having definite valvular disease. The latter figure is comparable to the 0.5 per cent of acquired heart disease found to exist in Philadelphia school children in a study by Cahan² made in 1934 to 1936.

In looking over the records it was found that in an appreciable number of instances abnor-

mal findings referable to the heart were noted in which the physician did not offer any diagnosis to amplify his clinical signs. About one-half were referred to the family physician for further study, but since the others were not mentioned in the summary, the physician apparently attached little importance to his findings. A search for other than rheumatic etiology revealed that 4 of this group, 1 of whom also had rheumatic fever, gave a history of having had scarlet fever. Upon further investigation, the majority in this undetermined group would probably be found to have no organic heart disease.

Brief mention of the results of the blood pressure determinations on 733 individuals in the 10 to 14 age group may be of academic interest. Of this number, 59 per cent gave a systolic reading of from 100 to 119, and 77 per cent of them gave a diastolic reading of from 60 to 79. In the other age groups the numbers were too small to derive any conclusions.

Examination of the lungs revealed that 8, or 0.8 per cent, had an acute bronchitis at that time, 1 had asthma, while, in 7, certain abnormal findings were present which indicated the necessity of further study with, possibly, an x-ray.

A genital examination was not done in the girls, but 391, or 91 per cent of the 471 boys, were examined. Of the latter, 4 had an indirect inguinal hernia, a rate of 1.2 per cent for those examined. In addition, 11, or 2.8 per cent, had a unilateral or bilateral undescended testicle, while 41, or 10.5 per cent of those examined, were said to have phimosis. One case of hypospadias was found.

Orthopedic Examination

Abnormalities as found by the Division of Orthopedics were placed in two classes: first, those who were considered as having true orthopedic problems and who were referred to an orthopedist for further care and, second, those who showed moderate and severe foot and postural deviations but who presented no subjective symptoms.

In the first group of 86 individuals are included those foot problems with pain, in addition to those with any other clinically positive sign, such as irritation of bony areas, hammer toes, etc. There were 19 children referred for painful flat feet, 14 for a scoliosis, 9 for short lower extremities, and 4 for an epiphysitis of the spine. Two of the number showed rachitic deformities, and the same number had a wry neck and arthritis, respectively. One indi-

Cost of Demonstration

An effort was made to estimate the cost of this demonstration, which was borne by the cooperating agencies. Included is the honorarium paid the examining physicians, time spent by the personnel of the State Health Department in the actual examinations, nurses' time, 4-H Club agent's and assistant's time, clerical work, supplies, and cost of incidental travel, which total amounted to \$2,646. This was approximately \$2 50 per examination.

Discussion

To evaluate this demonstration at the present time is an impossibility. One cannot doubt the educational value of a properly conducted physical examination. However, the end result can only be measured by the benefits incurred through meticulously carrying out any recommendations made. An effort will be made in the spring of 1942 to determine whether or not sufficient interest was aroused to make the procedure worthwhile.

Summary

A demonstration health program in the 4-H Clubs of Delaware County was begun in 1940 by examining the members, an analysis of the findings being presented.

Those in the 10 to 14 age group constituted a fair sample of that group in the county.

Dental care was needed by 43 per cent of those examined.

The diet was inadequate in 35 per cent of the group and 10 per cent drank no milk.

Correction for visual errors was needed by 30 8 per cent of the group.

Pathologically enlarged tonsils were present in 22 9 per cent.

About 14 7 per cent had some loss of hearing and 1 4 per cent had a chronic otitis media.

An orthopedic problem was presented by 8 4 per cent, and 65 per cent showed foot and posture deviations.

Definite malnourishment was said to be present in 5 2 per cent.

Acquired heart disease was present in 0 7 per cent.

Only 5 4 per cent of the group were classed as having no defects.

. . .

Grateful acknowledgment is given to Dr T J O'Donnell, Division of Orthopedics, New York State Department of Health, for analyzing the orthopedic findings and to Miss Margaret Graff, Statistician, Division of Local

vidual was diagnosed as having Osgood Schlatter's disease, 1 showed an internal derangement of the knee joint, and 1 showed a hallus valgus.

Falling in the second classification are 671 individuals who showed moderate and extreme foot and posture deviations. Although it was felt that all of the 1,028 youths examined might profit by posture training, this group in particular would be benefited by properly supervised corrective exercises. Individual recommendations were made in each instance when Thomas heels or lifts on the shoes were thought advisable.

Table 1 is a summary table showing the various abnormalities noted. Not mentioned previously are included 38 with slight or moderately enlarged thyroids and 4 persons who showed evidence of an endocrine disturbance. Counting only the defects shown and excluding the incidental acute conditions picked up, it was found that only 57 individuals, or 5 4 per cent of those receiving a physical examination, were considered normal. An additional 144 had only some orthopedic defect, so that had the group not been examined by an orthopedist 19 per cent would have been considered in good health.

In many instances it was impossible to make a definite diagnosis on the single examination. No doubt many of the suspected abnormalities will subsequently be ruled out by the family physician.

Health Administration, New York State Department of Health, for compiling the data

THE PHYSICIAN'S ROLE IN A COUNTY 4-H HEALTH PROJECT

THOMAS C. MONACO, M D, Walton, New York

PREVENTIVE medicine has always been accorded a deservedly high position in the medical Utopia toward which we continuously grasp, even though we never quite reach it. Recently, however, the importance of prophylaxis in disease has been more forcibly emphasized by certain events and by certain facts. The events, of course, are those of the present worldwide upheaval which have caused us to take stock not only of machines and raw materials but also of the tangible asset of national health. The facts that have aided in bringing both lay and medical attention to the importance of prophylaxis are those gained in the fight against tuberculosis, cancer, diabetes, and other less publicized diseases. All of us seem more or less agreed now that public health measures may eradicate an infectious disease like tuberculosis long before a specific remedy is discovered. Then, too, advertisements of the insurance and drug houses in nationally distributed periodicals have long stressed the advisability of annual examinations as a routine health measure.

In line with these tendencies, the Delaware County Medical Society voted last fall to undertake the examinations of the 4-H children who signed up under the health project that Dr Rogers has so well described. A committee was appointed which assigned the physicians who volunteered to localities other than their own local communities. The committee decided that it was advantageous for a doctor to examine a child he had never seen before if possible, since this would tend to liven his interest in the examination. It was reasoned that an examination by another than the child's usual physician ought to be more objective and impersonal.

After the project was completed, certain questions arose in the minds of the examining physicians. First was the time taken in each examination enough to complete a satisfactory

physical examination? It is true that the average number of children examined was 10.7 per doctor per three-hour session. But actually the working time per session was only two and one-half hours or less, and the number to be examined was often as many as 18. This made the actual examining time as little as seven minutes in some instances although as much as twelve minutes in others. With doctors as far as fifteen to eighteen miles away from the examining center, it was difficult to correct immediately a situation where there were too many examinees. On one afternoon, for this reason, 1 doctor examined 39 children in five and one-half hours. This was exceptional, of course, but stressed the importance of knowing nearly exactly the number to be examined. The consensus, however, was that even eight minutes permitted a fairly careful checkup of the child's condition if he had been stripped and weighed and had had his history, visual, and hearing defects already noted.

Second, we asked ourselves whether the information derived was worth the expenditure of time of the doctors, health officers, nurses, and clerical staff, as well as actual outlay of federal funds and materials. Dr Rogers has mentioned \$2.50 as an estimate of the cost of each examination, and in reviewing her figures I certainly feel that this was a conservative rather than a generous estimate. In general, however, we agreed that the facts uncovered about these children were well worth the price paid, assuming that these defects had not been already noted in their school examinations. We felt that the examinees were an excellent cross section of all the children in Delaware County and that they could be leaders in other health projects. If the defects were followed up and corrected, there could be an incalculable saving by correcting as youths the physical faults that in later years would cause an expenditure of time and money, as well as a waste of the invaluable community resource of health and well-being.

Third, in answer to the implied question just mentioned, we wanted to know if data over and above those already amassed in the school examinations were found or whether we were simply repeating a job unnecessarily. Remembering that in nearly all instances the visual and hearing tests and the height and weight measurements were taken from school records or else checked by the nurses present and also noting that the teeth had been just as carefully checked, if not more so, by dental hygienists or school physicians, it was decided that nothing at all had been added to the group of defects which, together, comprised a total greater than the orthopedic faults that headed the list. In the latter instance none of the school doctors pretended to have either the specialized knowledge or the time to complete as excellent an orthopedic examination as the state orthopedists made. The state orthopedists acknowledge too that a great number of the foot and posture deviations are borderline cases requiring little or no care and that the true orthopedic deficiencies lay in the smaller number of 86, or 8.3 per cent of the 1,026 receiving such examinations. We decided, therefore, that the advantage of such a project as this, would have to rest in the follow-up. With the interest of the children aroused because of the competitive nature of the project and with 4-H leaders and parents alike knowing and checking the aftercare, there should be a greater percentage of corrections than would follow simple compulsory school examinations. It is still too early, of course, to answer that question. The children are supposed to be re-examined in one year and improvements are to be noted. In passing, however, most of the physicians seem to have had my experience with the follow-up to date—namely, out of 35 examinations reported of which 26 required treatment, just 7 children or parents have been in to discuss the reports, and only 3 have completely followed the advice offered. Perhaps our Utopia will always thus elude us.

It is impossible to close without alluding as Dr. Hiss has, to some of the similarities between the list of defects in this project and the

lists for the Selective Service Act rejects. Of course, the percentages rejected for each defect are lower, since the Army will take a certain minimum deficiency in its soldiers and we tried to allow none in the 4-H children, but there was a lesson to be learned nonetheless. Of 6,743 men examined in the second corps area from June through August, 1940, 2,195 were rejected, of which 23 per cent were for teeth, 21 per cent for eyes, 15 per cent for height and weight abnormalities, and 10 per cent each for ear and feet defects. In the last World War orthopedic faults led the list, with visual, cardiovascular-renal, dental, and underweight deficiencies close behind. It was obvious after studying the reports that the only way to have a healthier adult is to find and correct the physical failings of the boy and girl of the age group examined in this project. While that statement seems true or at least undeniable, it is amazing how little is done about it. Any physician examining draftees today is impressed by the number of remediable faults that cause rejection.

Summary

Studying the results of this 4-H health project from the physician's point of view, the following conclusions seem tenable:

1. In examining large numbers, proper preparation of the subject is essential. If ordinary measurements are taken, as well as a good history, and if visual and hearing tests are made (preferably with an audiometer), the rest of the physical examination can be completed in ten to twelve minutes.

2. The information derived was important and worthwhile, but not worth \$2.50, since the examinations were a repetition of the school examination with the exception of the orthopedic.

3. If the school examinations were properly followed up by parents and school nurses there would be more than enough opportunity for correction without additional fact-finding. In addition, if school examinations were made more complete, with perhaps an annual check-up by an orthopedist, a project such as this would be redundant.

AN OVERDOSE

Steinmetz, of General Electric fame, defined a highbrow as "any person educated beyond his intelligence."

MEDICAL PRACTICE FOR BODY AND MIND

HAROLD INMAN GOSLINE, M D, F A C P, Ossining, New York

IT MAY be summarily stated that, historically, this subject is as old as the problem of matter and of mind, and it may be considered as one aspect of that controversy. My immediate inspiration was one of my medical school teachers, Dr Elmer Ernest Southard, Bullard professor of neuropathology at Harvard Medical School and for many years pathologist to the then "State Board of Insanity" of the Commonwealth of Massachusetts. I recommend to you his biography not only for your own perusal but for your families' with special reference to any serious-minded youngsters of high-school age. It is called *The Open Mind** and was written by Dr F P Gay, late professor of bacteriology at Columbia Medical School.

I have been privileged in the more than twenty-five years since my graduation from medical school to elaborate on one aspect of the many projects outlined in their most general terms by Dr Southard.

Plunging at once into the midst of things it may be convenient to compare the situation of the individual person to the surroundings and state of a tree. Realizing that the analogy is incomplete and that it will break down if pushed too closely into detail, let us assume categorically that the branches may roughly represent the main divisions of his social activities, that the secondary branches and twigs may represent the subdivisions of these social activities, and that the foliage—blossoms, leaves, and/or fruit—may represent the words (written or spoken) and the gestures by which social communication and contact are made possible.

Again speaking in metaphor and only by analogy, the trunk of the tree is the structure or organ in which courses the fluids, the processes of the flow of which may be likened to the flow of the mental processes. This similarity, which seems so tenuous particularly at this point where "mind" is concerned, becomes strikingly clear and convincing when one realizes that the search for the "mind" on the somatic level, as revealed by recent electroencephalographic studies,* shows only elec-

trical waves of varying amplitudes and frequencies. These may be likened to the fluids in the trunk of the tree, the flow of these fluids which is "function" then represents the "flow of the mind" which is "structure," and the trunk of the tree which is "structure" is the brain of the man which is structure. Whether the listener acknowledges or accepts the analogy is an incident of little if any moment but the speaker would request that the audience keep in memory the essential distinction of importance, namely, that made between "structure" and "function."

Pressing once more to the analogy, the main roots and rootlets, together with the root mass in complex profusion, correspond to the bodily organs, to their subdivisions and fine cellular structure, while the physicochemical processes that take place there have an analogic counterpart metaphorically in the biochemical processes of bodily organs. These biochemical processes are rapidly and extensively being incorporated with the great treasures of chemistry and physics collectively known as physical chemistry with its subdivisions of structures and processes or functions.

As an oak tree grows from an acorn and not from a beechnut so, in general, among humans and animals the laws of heredity are controlling. Though we realize that cross-fertilization is possible in all branches of the great human family, we have not yet determined which hybrids are potentially valuable and which are worthless. All we know now in this particular is that certain hybrids are repulsive to persons of finer sensibilities and keener understanding. This paragraph makes no claim to completeness on the great and important matter of heredity, but it is all that can be said here.

Just as foliage—blossom, fruit, or leaf—of one tree does not affect foliage of another directly but only through some medium, such as air or the ground upon which it falls, and decays into its chemical constituents, so also words (written or spoken) and gestures do not affect the mind of another directly—"telepathically"—but only by the medium of the air and of the "ether." The former is well known but the latter is still only a construction of physicists, tentatively set up to explain certain phenomena and never yet

* Items noted with an asterisk denote a literature too large to set down in this brief article.

Presented at the Lions' Club of Ossining New York on January 23 1940
From the Institute for Social Adjustment 275 Spring Street Ossining.

quite entirely satisfying to all the conditions known or surmised from experiment. In terms of physiology the former is well known as "hearing," and the latter is still being studied as "vision."

Sound and light, the first in the form of the spoken word and the second as written words and gestures, are taken up through the bodily organs with particular reference to the end-organs and nerves—the ear and the eighth nerve for sound, the eye and the second nerve for light.

That the constituents of the fluids in the tree arise not only from the rot of the leaf and the fruit but also from the other components of the soil in which the roots are embedded is a matter of such general and common knowledge that no elaboration appears to be needed. It is, perhaps not so clearly evident to the layman of nonphilosophic training that in him also it is not only what he sees and hears that affects all his functionings called "mental" but that it is also all the other constituents of his milieu, environment, or surroundings which improve or impede the power and the force and complexity of the mental functionings of which he is capable.

The point will be accepted at once when I say that in the clear, cool atmosphere of the mountain one's faculties are refreshed and invigorated, while in the smoke of the slum of the city the deadly carbon monoxide does not help, assist, or favor any mental or bodily function. It is not necessary to go into detail about anesthetics, soporifics, somnifacients, or narcotics to convince men of average intelligence that substances taken by ingestion (which is gastrointestinal) or by inhalation (which is pulmonary) may also affect the functionings called "mind" from the slightest perceptible traces to the depths of the most complete abolition. On the other side of the picture are the stimulating effects of the caffeine in a good aromatic-like coffee. The assumed similar effects of alcoholic beverage are not what is popularly imagined but are really due to the depression effected upon the inhibiting centers of higher intelligence, thus releasing those more spontaneous functions of emotional and personality responses which lend themselves so delightfully and charmingly to party conviviality except when it sometimes happens that others of more animal nature chance to be in attendance at such places and are unable in the words of the Southland "to carry their liquor like gentlemen."

However, it should be stated at once,

without quibbling, that "somatopsychic medicine" is not concerned with such comparatively easy problems. In fact, it may be stated promptly that present-day "body-mind medicine" could not exist as a practice if it were not for the advances of science in the fields of immunochemistry* and in the chemistry of glands* and nutrition* with special reference to the processes of oxidation,* reduction,* and deamination* and if it were not for the parts played by enzymes* and electrolytes* in the intimate chemical exchanges that subserve those functionings called "mind."

I regret that I can only mention these matters, but I hope that they will arouse curiosity which may lead to an earnest and desirable interest. I must proceed to a related matter which may prove to be of utmost importance in the brief space of scientific advancement which is infinitely brief in comparison with the millenniums about which the geologists tell us but which seems long and roundabout, if not tedious, when measured in the more finite figures which apply to the lifetime wherever the individual is considered.

We now have evidence before us the interpretation of which is still in the balance. It is known that in many diseases a trace is left after the illness is over. This remainder is perhaps like a "hang-over", in technical terms it may be a "residual." While its intimate nature is still undetermined, it is a matter of widespread knowledge that diseases like syphilis, scarlet fever, and diphtheria, as well as tuberculosis, pneumonia, and hruccellosis, leave a trace which is detectable by methods well known to competent pathologists as well as to many practitioners.

These serologic* and skin tests* have raised another and more momentous inquiry as to whether other diseases, not syphilis, may also run a course in three stages. Even the positive Wassermann gives no direct or conclusive evidence as to the presence or absence of a continued treponemal invasion. So, also, a positive skin test, for example in undulant fever,* neither proves nor denies that the etiologic agent is still present or absent completely. While this question remains to be answered in these and still others where posited, there are a number of important diseases where the question has not yet even been raised. Among these are the common diseases of childhood together with gastrointestinal and infections of the upper part of the respiratory tract. Under the terms of this theory, each case of these common ail-

ments should be considered by every practitioner as a possible cause for further concern at some future undetermined date. It is for this reason and others that a routine physical checkup should be made at least once or twice yearly, with the possibility in the mind of the doctor that he may be on the path of discovery of complications or of sequelae of a previously neglected condition. It is here that the close observation of the keen and observant physician may solve the enigma quite early and thus save the full-blown catastrophe. However, in my opinion, it is not enough to be an observer, in order to do the job properly, resort should be had to the laboratory. If the overhead looks expensive and heavy, then arrangement should be made by some other method, but the scientific aid of the laboratory should in no case be slighted or neglected. No organ or system of "soma" is of such insignificant value that it may not yield information of vital and crucial importance for the healthy functionings called "psyche." In fact, it may be stated dogmatically that, at times, it is not character or temperament or any of the other intangibles that go to make up the "psyche" but some common somatic organ that needs treatment and careful attention. It would seem as though each organ in "soma" may be, in its disorder or illness, a possible and unerring indicator of the nature of the etiologic agent. Thus, for example, it appears² that a substance may be released in some instances by the action of some childhood infection, that this substance may then form a union with a fraction of the invading bacterium, and that, finally, this newly formed compound may damage not only the organ of its primary origin but also some other more distant related structure, the connection possibly being some microscopically similar unit perhaps in the supporting framework of otherwise dissimilar organs. Thus, a study of kidney damage with a history of scarlatinal infection may contain the key situation to another injured focus, perhaps in some cases the brain. The possibilities of this new and striking discovery are so many, so broad, and so inviting that, in the words of another investigator, the outlook is "fairly bewildering."

My early studies³ and studies of others have shown fairly succinctly and clearly that the mental symptoms of illness also follow a definite pattern, that first there are signs of the stimulus that comes with the primary invasion, that later these acute signs fade out more or less in their action, and that, finally,

with long continuation of the disease that produces the picture, the mental symptoms themselves also wane to a level of demented nonreaction.

Further study with our childhood diseases has yielded the most fascinating conclusion⁴—namely, that not only stupidity but even precocity itself and sometimes brilliance is not only not to be viewed with self-satisfaction but is rather to be carefully followed to determine how far it is normal and how far it is the result of some illness.

Carrying over a similar notion into the field of delinquency and crime, I⁴ have found that the impeny of juvenile and of adult criminality may frequently be traced, without effort, to the onset of some childhood infection. Confirmation of this observation is open to any well-trained pathologist who will take the necessary trouble and time to make the needed examinations and studies. The bodies of electrocuted criminals,⁴ whether aged, middle-aged, or young, will reveal evidences of damage and of retardation which have no relation to electrical current. Thus, the fixation of somatic development at a stage that would be normal in a younger person closely parallels what we know of the "psyche" of the young criminal or the old recidivist. Their intelligence may be above normal, but their temperament and character show deviations which are accurately classified together as evidences of slowness of development. Fixations at infantile levels account for their puerile conduct. Perhaps it is a similar condition, a "hang-over" in the more nearly normal, which produces the playboys and others who contribute to social disorders. In this detail it would not be amazing, when we consider the universality of the infections and malnutritious of childhood, if some scientist were later to discover that the inability of the race to find ways out of its social dilemmas is due to the failure to develop that maximum degree of attainment which is needed for the complete elucidation of these most complex of all human problems.

Reverting to analogy and metaphor, the somatopsychic physician "tills the ground" for the somatic root mass. He attempts to prevent the advent of noxious influences and agents—infections or insidious foreign propagandas. His theory brings a clear realization that, whether growing or grown, the acceptance and incorporation of harmful agents, whether germs or adverse situations, can have but one effect upon the mind, at least in tendency, and that is to retard progress and

mental advancement to the goal of all human endeavor—the attainment of that harmony and beauty (whether of intellect, temperament, or character) which is the necessary and desirable precondition for the enjoyment of those aims of any free democracy—life, liberty, and the pursuit of happiness

In the words of the ancient Latins, the objective of the somatopsychic theory and practice is the accomplishment and fruition

of the ancient ideal—*mens sana in corpore sano* (a healthy mind in a healthy body)—in a hectic, if not a chaotic, present-day world situation

THE SOCIETY OF THE NEW YORK HOSPITAL

Lewis Cass Ledyard, Jr., Fellowship

The Lewis Cass Ledyard, Jr., Fellowship was established in 1939 by a gift from Mrs Ruth E Ledyard, wife of the late Lewis Cass Ledyard, Jr., a governor of the New York Hospital. The income, amounting to approximately \$4,000 annually, will be awarded to an investigator in the fields of medicine and surgery or in any closely related field. This amount will be applied as follows \$3,000 as a stipend and, approximately, \$1,000 for supplies or expenses of the research. In making the award, preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. The recipient of this Fellowship will be required to submit reports of his work under the Fellowship, either at stated intervals or at the end of the academic year, and when the result of his work is published he will be expected to give proper credit to the Lewis Cass Ledyard, Jr., Fellowship. The research work under this Fellowship is to be carried on at the New York Hospital and Cornell University Medical College. The fellowship will be available on July 1 at the beginning of the academic year. Applications for the year 1942-1943 should be in the hands of the Committee by December 15. It is expected that the award will be made by March 15, 1942.

Application for this Fellowship should be addressed to

The Committee of the Lewis Cass Ledyard, Jr., Fellowship
The Society of the New York Hospital
525 East 68th Street
New York, New York

PHYSICIAN, DUST THYSELF

Dr W H G Logan, dean of the Chicago College of Dental Surgery, recently addressed an audience of doctors and dentists in Wichita, Kansas, as reported in the *Wichita Medical Bulletin*. Many of us, he said, are prone to complain to our office girl that the fixtures have not been thoroughly dusted. We complain to the building manager that the walls or floors are not kept up as they should be. We become tired of our office furniture and have it refinished, or perhaps buy new. We look at our surroundings with critical eye and when dissatisfaction be-

comes too disturbing we do something about it. "But," he interrogated, how often do you look at yourself as an individual—as a human entity? What are you doing about that mind? Have you recently stepped out of yourself, stood at a distance and with critical eye evaluated yourself physically, spiritually, intellectually? You owe it not only to yourself but to your patient to do so. Your patient comes to you with confidence and trusts that you can help him. You must keep yourself well dusted if you are to serve him best."

Case Report

THIAMINE CHLORIDE IN THE TREATMENT OF DIABETIC ACIDOSIS

JAMES RALPH SCOTT, M D , F A C P , New York City

A DIABETIC, white, American housewife, aged 64, was admitted to St Luke's Hospital on November 27, 1940, in diabetic acidosis. She had been a diabetic patient for sixteen years and was adequately controlled on 30 units of protamine insulin daily. The morning of the day before admission she forgot to take her usual insulin. The evening before admission she felt well. She had a cocktail before dinner and ate more than usual. She awakened at 1 00 A.M. with vomiting and abdominal pain. At 8 30 A.M. when seen by me, she was lethargic and slow in speech but was conscious and coherent. A physical examination was essentially negative except for a slight hyperpnea, pulse, 90, oral temperature, 99 F., and blood pressure, 110/80. When admitted to the hospital at 9 40 A.M. the hemoglobin was 85 per cent, red blood count, 4,300,000, white blood count 9,500, polymorphonuclears, 88, lymphocytes, 7, monocytes, 4, eosinophils, 1, blood sugar, 288 mg. per hundred cubic centimeters, CO_2 , 16.4 volumes per cent, urine sugar, 1.2 per cent, and acetone, xxx .

The blood chemistry, urinary findings, insulin dosage, and fluid intake are summarized in Table 1.

The patient remained in the hospital for three days, leaving the morning of the fourth day. She has been well since and is adequately controlled on her former diet and protamine insulin dosage.

On admission the patient was placed on our acidosis routine as outlined. For the first twelve hours she was unable to take any nourishment by mouth. During this period she received 465 units of insulin and 4,500 cc. of 5 per cent glucose in physiologic saline intravenously. Total carbohydrate was 225 Gm. The second day she was placed on our fluid diet. Unmodified insulin was given as indicated by the urinalyses. Orange juice was given in addition to the diet if the urinalyses indicated a need for it. The third day she was placed on our beginning diabetic diet with a value of carbohydrates 130, proteins 65, and fats 50. Protamine insulin was given for the first time on the third day with additional unmodified insulin as indicated.

When large amounts of fluid are given by vein (or by mouth) the excretion of thiamine in the urine is increased.¹ This tends to create a thiamine deficiency. The need for thiamine varies directly with the carbohydrate calories assimilated. For twenty-four hours the only food this patient received was 225 Gm. of glucose. This increased her need for thiamine. She was subjected, therefore, at one and the same time to an increased loss of thiamine and an increased need for thiamine. Add to this a possible chronic suboptimal thiamine intake due to the American habit of eating plus the restrictions inherent in a diabetic diet, and the assumption of a developing

thiamine deficiency is justified. Therefore, thiamine chloride, 50 mg., was given intramuscularly once daily.

It was not until the patient was discharged and the chart reviewed that the apparent favorable effect of the thiamine chloride on the course of the acidosis was discovered (Fig. 1).

For the first six hours the patient was intensively treated. During this period she received 3,000 cc. of 5 per cent glucose in saline (150 Gm. carbohydrate) and 270 units of unmodified insulin. During this period of intensive therapy her CO_2 rose from 16.4 to 19.2 volumes per cent—practically no rise at all. As great a difference as this may occur from changing technicians. But in the next three and one-half hours the CO_2 rose from 19.2 to 40 volumes per cent. In half the time it took to increase by 2.8 volumes per cent, it increased by 30.8 volumes per cent!

This appeared to be an unusual acceleration of improvement. In searching for a cause, it was discovered that the thiamine chloride happened to be given two hours after the 19.2 volumes per cent reading and an hour and a half before the 40 volumes per cent reading. One is tempted to assume that the thiamine chloride may have effected this improvement.

It appears that there is a theoretic basis for supposing that such an effect might have been predicted. It has been definitely established that pyruvic acid, an intermediate metabolite in the oxidation of carbohydrate, accumulates in the blood as a result of thiamine deficiency.¹ Pyruvic acid is a ketone body. Its accumulation in the blood diminishes the alkaline reserve. When thiamine is given in adequate amounts, the excess of pyruvic acid is removed and the alkaline reserve returns to normal.¹

It is my contention that the sharp acceleration in improvement of the alkaline reserve observed following the administration of thiamine chloride to this patient was due to the removal of accumulated pyruvic acid from the blood.

It is not suggested that an accumulation of pyruvic acid in the blood is the sole cause of the diminished alkaline reserve in diabetic acidosis, but it may very well be a contributing cause in the presence of thiamine deficiency. Of course, if thiamine deficiency does not exist, the administration of thiamine chloride would have no effect whatever on the restoration of a normal alkaline reserve.

Diabetic acidosis may, therefore, at times be due to two components. First, an accumulation of the well-known ketone bodies—acetone, diacetic acid, and beta-oxibutyric acid—and, sec-

* A record of three days' treatment of a case of diabetic acidosis. The thiamine chloride was given intramuscularly. Most of the urinalyses were done by the attending nurse using Benedict's qualitative solution. The results are recorded as orange (o) yellow (y), green (g) or blue (b). At intervals more complete analyses of the urine, including tests for acetone, were performed in the laboratory with results recorded in grams per hundred cubic centimeters.

FIG 1—The thiamine chloride was given the first day two hours after the 19 volumes per cent reading was made, and one and one-half hours before the 40 volumes per cent reading was made.

On the second day it was given four hours after the 28 volumes per cent reading was made and eight hours before the 40 volumes per cent reading was made. The insulin figures represent the amount of insulin given during the periods between successive readings of the CO₂ volumes per cent.

and, an accumulation of the lesser known ketone body, pyruvic acid. The specific treatment for one is glucose and insulin. The specific treatment for the other is thiamine chloride. Physiologic saline is given for both conditions.

In diabetic acidosis under treatment it is frequently found that acetone disappears from the urine but that the blood CO₂ remains low. That means that the component of the acidosis which was due to a lack of insulin and glucose has been removed. It is suggested that the remaining component may be due to thiamine deficiency with its resultant accumulation of pyruvic acid in the blood. The prompt restoration of the alkaline reserve in this patient following the injection of thiamine chloride strongly suggests that this patient was suffering from a deficiency of thiamine.

It is admitted that the evidence supplied by this single case is incomplete, but the sequence of events is most suggestive and is a challenge for further investigation. This investigation is being undertaken and will be reported in a subsequent communication.

Meanwhile, would it not be wise to give liberal

November 1, 1941]

doses of thiamine chloride to all patients in diabetic acidosis on the assumption that they may be deficient in thiamine? Until a simple chemical method is devised to measure the concentration of pyruvic acid in the blood, the administration of thiamine would be purely empiric. It would at least do no harm and in the presence of a thiamine deficiency would accelerate the restoration of a normal alkaline reserve.

Summary

1 A case of diabetic acidosis is reported in which the alkaline reserve was promptly restored to normal following the injection of thiamine chloride.

2 It is suggested that diabetic acidosis may frequently be complicated by a thiamine deficiency with a consequent reduction of the alkaline reserve due to the accumulation of pyruvic acid in the blood.

3 It is further suggested that thiamine chloride be given to all patients in diabetic acidosis on an empiric basis until further investigation proves or disproves its administration as a sound physiologic measure.

Postgraduate Courses

A course on internal medicine from the Department of Medicine of the Long Island College of Medicine has been arranged by Dr Albert F. R. Andresen, of Brooklyn, for the Cortland County Medical Society at the Staff Room of the Cortland County Hospital on Friday evenings at 8 30. The lectures follow:

October 24 "Dietary Therapy in Gastrointestinal Disease," by Dr Albert F. R. Andresen, professor of clinical medicine, Brooklyn.

November 7 "Practical Considerations of Blood Dyscrasias," by Dr Eugene R. Marzullo, clinical professor of medicine, Brooklyn.

November 21 "Some Problems in Cardiac Diagnosis," by Dr Nicholas J. DiGregorio, instructor in medicine, Brooklyn.

December 5 "Diabetes Mellitus—Its Modern Interpretation and Treatment," by Dr Milton B. Handelsman, assistant clinical professor of medicine, Brooklyn.

December 19 "Some Problems in Pulmonary Disease," by Dr Richard H. Bennett, clinical professor of medicine, Brooklyn.

A course on general medicine (No. 1) was arranged by Dr Walter W. Palmer, College of Physicians and Surgeons, Columbia University, New York City, for the Nassau County Medical Society. The following lectures are held at the South Nassau Communities Hospital, Rockville Centre, at 4 00 P.M.

October 20 "Diabetes Mellitus," by Dr David D. Moore, New York City.

November 17 "Rheumatic Fever," by Dr Alvin F. Coburn, assistant professor of medicine, Columbia University, College of Physicians and Surgeons, New York City.

December 15 "The Diagnosis and Treatment of Anemia," by Dr Paul Reznikoff, associate professor of clinical medicine, Cornell University Medical College, New York City.

January 19 "Diseases of the Heart," by Dr Harold E. B. Pardee, assistant professor of clinical medicine, Cornell University Medical College, professor of internal medicine (cardi-

ology), New York Post-Graduate Medical School, New York City.

February 16 "Asthma," by Dr Robert A. Cooke, assistant professor of clinical medicine, Cornell University Medical College, New York City.

March 16 "Syphilis," by Dr Leshe P. Barker, New York City.

April 20 "Nephritis," by Dr Dana W. Atchley, associate professor of medicine, Columbia University, College of Physicians and Surgeons, New York City.

The lectures on "Rheumatic Fever" and "Syphilis" are a cooperative endeavor between the State Department of Health and the Medical Society of the State of New York.

Dr Walter W. Palmer also arranged a course on general medicine for the Oswego County Medical Society at the Elks Club, Oswego, at 8 30 P.M. The program follows:

October 22 "Rheumatic Fever," by Dr Alexander T. Martin, clinical professor of pediatrics, New York University College of Medicine, New York City.

November 7 "The Diagnosis and Treatment of Anemia," by Dr Paul Reznikoff, associate professor of clinical medicine, Cornell University Medical College, New York City.

November 19 "Diseases of the Heart," by Dr Charles A. R. Connor, instructor in medicine, New York University College of Medicine and the Cardiac Classification Service, New York City.

December 3 "Nephritis," by Dr John D. Lytle, assistant clinical professor of pediatrics, Columbia University, College of Physicians and Surgeons, New York City.

December 17 "Treatment of Chronic Rheumatism (General Medicine, No. 4)," by Dr Russell L. Cecil, professor of clinical medicine, Cornell University Medical College, New York City.

The lecture on "Rheumatic Fever" is a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the December 1 issue and will concern "Management of the Menopause."

Treatment of Chronic Nephritis

DR CLAUDE E. FORKNER The subject of our therapeutic conference is "The Management of Chronic Nephritis." We are glad to have Dr. H. O. Mosenthal here to introduce the discussion.

DR H. O. MOSENTHAL I am glad to be back here again. It was long ago that I was an intern at this institution.

In this discussion I am taking for granted that etiologic factors such as foci of infection, pyelitis, mechanical obstruction of the ureters and urethra, etc., have been taken care of and that the chronic nephritis is established beyond curative redemption. The treatment resolves itself into, first, prevention of the progress of the nephritis and, second, keeping the patient fit, enabling him to participate in all activities in full measure while life lasts—and it often continues for a long time.

The notion of a generation ago that a low protein diet shields the kidney apparently will not down, despite the fact, which needs no proof, that starvation or semistarvation results in malnutrition and in degenerative changes in all tissues, including the kidneys. Furthermore, an elevation of urea or nonprotein nitrogen in the blood is harmless, does not produce uremia, and may even be beneficial in that it provides a splendid diuretic stimulus.

There is no formula for the management of chronic nephritis, as is implied by the oft-recurring question "What is the treatment for chronic nephritis?" The treatment of chronic nephritis is almost entirely symptomatic and is largely governed by the symptom complex that dominates the disease picture at the moment. Consequently, the therapy varies greatly, not only from patient to patient, but also at different periods in the same case.

The disturbances, any one of which may develop as the paramount influence in chronic nephritis, are three: (1) albuminuria, (2) hypertension, and (3) renal insufficiency.

These are the hubs of the wheel from which

various sequelae originate. The complete word picture of these syndromes is this:

- I. Albuminuria
 - 1. Hypoproteinemia
 - a. Edema
 - 2. Hypocalcemia
- II. Hypertension
 - 1. Heart
 - a. Hypertrophy—dilatation
 - b. Coronary thrombosis
 - 2. Brain
 - a. Thromboses—hemorrhages
 - b. Encephalopathy
 - 3. Kidneys
 - a. Nephrosclerosis
- III. Renal insufficiency
 - 1. Anemia
 - 2. Retention uremia
 - a. Acidosis
 - b. Hypocalcemia
 - c. Chloride retention or loss

Albuminuria—Thus far, no remedy has been discovered which will check albuminuria. On lying down, about half as much albumin is lost in the urine as in the upright position. This may be the reason why some patients with nephrotic edema exhibit a diuresis and loss of weight when they are put to bed.

Hypoproteinemia.—This will inevitably occur when the albuminuria is marked 1 per cent or more and prolonged. A high protein diet is the main prophylactic and curative measure. Amounts of protein up to 200 Gm per day and more have been advocated. Such quantities of protein do no harm and are of great benefit. However, the appetite of most nephritic patients falters when they are confronted with such a diet, and in the average patient it is an achievement to have them attain the criterion of protein intake set up by Peters and Bulger—of 75 Gm plus the quantity of albumin lost in the urine. In addition

to alleviating hypoproteinemia, a liberal protein intake is of aid in stemming the development of anemia and also, as I have had the opportunity to observe in several cases that had previously been on a prescribed lacto-vegetarian diet, it will lower hypertension and will relieve albuminuric retinitis.

All the food proteins have not yet been studied in regard to their power to form blood and body proteins. In the order of efficiency, according to Weech, they are beef serum, egg white, beef muscle, beef liver, casein, and gelatin. All of these appeared to be good protein restorers except gelatin, which showed a negative value. Dried beef serum, desirable as it may be from the nutritional point of view, has thus far not been supplied in palatable form.

Thus far, the systematic infusion of plasma or amino acid preparations has yielded no satisfactory or conclusive results, although when these procedures are perfected they should become most valuable.

Acacia infusions to raise the osmotic pressure of the blood have been advocated and discarded in turn and are recently again sponsored by Goudsmit and Binger of the Mayo Clinic.

Transfusions, as a rule, do not serve to raise the level of the serum proteins, and it is useless to resort to them for this purpose.

Edema—The measures that remedy hypoproteinemia also prevent or cure edema. When the serum albumin drops in spite of treatment, reaching a level of 3 per cent or less, then edema may develop. The salt intake should be restricted as much as possible. The limitation of the fluid intake is not so important as that of the sodium chloride. Salt substitutes as marketed are usually sodium salts of some acids other than hydrochloric and inasmuch as it is the sodium moiety of the sodium chloride that induces water retention they are valueless. Potassium and ammonium chloride have been suggested as substitutes for table salt. Because of their bitter taste, they rarely become a routine part of the diet, they have to be taken in capsule form, 2 to 4 Gm a day and they will relieve some of the craving for salt and will have a distinct diuretic action.

The possible existence of cardiac insufficiency and the advisability of using digitalis have to be considered in every case. The purine diuretics are rarely employed except theophylline combined with the mercurials. Urea is a valuable diuretic in those cases in which the blood urea is not elevated. It is

not resorted to as often as it should be. No complications are caused by it. It is readily soluble and is administered in solution, about 10 Gm three times a day.

Thyroid has been advocated, in large, even huge, doses. The results have been somewhat disappointing. It may be that sufficient amounts have not been given. A good way to regulate the thyroid medication is to push it when the plasma cholesterol is elevated and to withdraw it as the cholesterol approaches a normal level.

The mercurial diuretics are the final resort when the nephrotic edema becomes a crippling complication. In cardiac conditions they have been found to be irreplaceable. Their use in nephrosis has been successful and has not damaged the kidneys. When a nephritis accompanies an edema there has been much hesitancy about using them. Some of us have had recourse to them in cases of chronic nephritis and have seen no harmful result. The mercurials, combined with theophylline, constitute the ideal diuretic, since theophylline promotes filtration of glomerular urine and mercury checks reabsorption of fluid and sodium chloride in the tubules, thus calling all parts of the nephron into action simultaneously. Acid salts, usually ammonium chloride or potassium nitrate, will enhance the effect of the mercurials but need not be employed in every case. They may, if administered without restraint, be responsible for a considerable degree of acidosis.

Hypocalcemia has thus far been regarded as a terminal event occurring in uremia. However, it often develops earlier in the course of chronic nephritis and produces symptoms that usually are comparatively slight, manifesting themselves as "cramps" in the extremities or abdomen, though they may be severe and come to the fore as full-blown tetany. The usual calcium medications by mouth may be used. In emergencies, calcium by vein may be necessary. The most reliable remedy for oral administration, just as it is in hypoparathyroidism, has proved to be dihydrotachysterol, or A T 10. The hypocalcemia probably results from the loss of calcium combined with albumin in the urine. Since we cannot control albuminuria, it is obvious that the deficiency of serum calcium must be rectified by symptomatic, in this case replacement, therapy.

Hypertension often becomes the dominant factor in cases of chronic nephritis and is a common cause of death in this disease. The control of hypertension, whether of the essen-

tial or the renal variety, has not been satisfactorily accomplished. Specific remedies that hit the bull's eye with even moderate regularity do not exist. The latest of these, potassium thiocyanate, has in my experience not been so completely successful as those who have advocated it have found it to be. However, the devastating reactions that have been attributed to it have failed to materialize when the dosage was guided according to the thiocyanate concentration in the patient's blood.

It is both surprising and gratifying how much can be accomplished for hypertensives by hygienic, physical, and mental adjustments in which selected drug therapy plays a big role. A permanently elevated blood pressure is one of the functional disturbances that is more effectively handled in private practice than in an institution. This does not gainsay that other methods of treatment, especially the discovery and remedying of unilateral renal impairments, are not of the greatest importance, and we live in the hope that the efforts of those investigators who are engaged in preparing a biologic preparation for the control of blood pressure will be successful.

Renal insufficiency, when marked and prolonged, results in uremia and death. The retention of urinary excretory products within the body in the long run causes two sets of symptoms: asthenia and toxic manifestations, ordinarily called retention uremia. We have learned to cope with the latter with a fair degree of success, but the former is still a mystery to us and patients succumb to it.

Anemia—J R Bradford in 1899 found that when three-quarters of the kidney substance is extirpated, in dogs, death takes place from asthenia without coma or convulsions. The asthenia is attended in human beings by anemia, which is the constant accompaniment of renal insufficiency whether this is caused by chronic nephritis or other renal or urinary tract impairments. The remedying of anemia in chronic Bright's disease is a major problem since the diminution in the hemoglobin and red blood cells may be a reason for disability and may be a contributing cause to a fatal termination. A high-protein, high-caloric diet will do a great deal in slowing the development of anemia. However, when renal function is severely curtailed it will not prevent the occurrence of anemia or its downward progress. The routine medications for anemia accomplish little. Iron, liver extracts, and vitamins are usually given in the customary fashion. They probably put the brakes on the downhill course, but their slight

effect is disheartening to both patient and doctor.

The really efficacious remedy for the anemia of chronic Bright's disease is transfusion. It must be understood at the outset that transfusions will return the blood count to normal but will accomplish nothing more than this, and any expectation that they will increase renal function or relieve the symptoms of uremia, is not warranted. On the other hand, transfusions produce no harmful effects. They will not elevate the blood pressure and are no more prone to cause reactions in chronic nephritic patients than in other persons. Since transfusions provide the only effective means of rectifying anemia in chronic Bright's disease, it is difficult to see why there has been so much opposition to their use. When the transfusions are used early—that is, before the hemoglobin and red cells are greatly diminished—one will do, but when the anemia has progressed to a point where the hemoglobin is down to a level of 50 per cent or less, then, as a rule, it requires three or four transfusions of 500 to 700 cc each to restore the blood to its normal level. As a rule, the first transfusion or two have no demonstrable effect, while the third and fourth result in a marked rise in the number of red blood cells. Direct transfusions have been much more satisfactory than indirect ones. I have come to appreciate this largely as a result of the demonstrations given me by Dr Lester Unger.

An interesting case in this connection is one of a boy of high-school age who was the victim of severe chronic nephritis. His anemia was rectified by frequently repeated transfusions carried out by Dr Lester Unger. Death resulted in an unexpected way. Marked hemorrhages developed rapidly. The blood was vomited and passed in the urine and the stools, and there were many large ecchymoses. The terminal tendency of chronic nephritis to bleed evidently was not prevented by maintaining the hemoglobin and red cells at a normal level.

Retention Uremia—Although the anemia may be considered as part of the effect of retention uremia, the accepted symptoms of actual retention uremia—marked lassitude, nausea, vomiting, coma, and convulsions—come on a long time after the progressive loss of hemoglobin and red cells has begun. Originally, it was thought that the accumulation of all the urinary excretory products, especially the urea, was responsible for the uremic symptoms, but this concept has come to be

modified so that, today, the generally accepted opinion is that the urea and the other nonprotein nitrogenous substances in the blood are not responsible for the uremic manifestations. The symptoms appear to rest largely on three changes—namely, acidosis, hypocalcemia, and either loss of or excessive rise of sodium chloride in the blood and tissues. We are in a position to remedy these disturbances by intravenous calcium, the administration of suitable amounts of alkalis, and the regulation of the salt intake. Consequently, the symptoms of uremia can usually be fairly well controlled, and our objective is largely to determine how well we can make nephritic patients continue to live with a mere 5 per cent of their kidney tissue remaining. Of course, this has its limitations and death occurs from asthenia. A week before life terminates, the blood pressure is prone to drop and assume a normal or even a subnormal level, although the general sense of comfort and well-being is not disturbed in all cases.

By meticulous care in meeting and remedying the changes that occur in patients with chronic nephritis their life can be prolonged a good deal. As long as they live, with the exception of a few weeks before death, they are active and useful citizens. The defeatist will, of course, ask what is the use of all this when in many instances a fatal termination cannot be avoided and the evil day is only postponed. However, as we have watched the subjects of chronic Bright's disease and seen them active, ambitious, and enjoying life, instead of going through months of chronic invalidism, the careful, symptomatic treatment accorded these patients has appeared to be distinctly worthwhile.

DR. FORENER. Before opening this interesting presentation to general discussion, I am going to ask Dr. Tolstoi to discuss it for a few minutes.

DR. EDWARD TOLSTOI. I just want to elaborate on one point, the mechanism of acidosis in nephritis, since the subject was covered so thoroughly. I am sure that Dr. Mosenthal is familiar with this picture as most of you probably are, but I will repeat it to fix it in our minds. The diet of any individual consists of proteins, carbohydrates, and fats, and that diet holds for the nephritic as well. Our proteins are composed of carbon, oxygen, hydrogen, nitrogen, sulfur, and phosphorus. The carbon, hydrogen, and oxygen are oxidized to CO_2 and water and excreted by the way of the lungs, skin, and kidneys. Nitro-

gen is excreted by the kidneys, and the sulfur and phosphorus are oxidized to SO_4 and PO_4 , respectively. Those are the two acid radicals, the accumulation of which in the blood stream results in the acidosis associated with the failing kidney.

The phosphate radical plays another important role. Since there is some calcium floating about, we have a combination of it with the phosphate, the compound being eliminated through the gut, establishing a low blood calcium level. The body attempts to compensate for the calcium want. The parathyroids are then stimulated, resulting in a compensatory hypercalcemia, and sometimes we find at postmortem that the parathyroids are enlarged. That is the mechanism of the renal type of acidosis as I have been accustomed to regard it. As to the mechanism of the toxemia, as Dr. Mosenthal mentioned, it is not due to the high blood urea. A person with a urea concentration of 200 or 300 mg may be about with few or no toxic symptoms, while another with 75 mg may be drowsy and reveal manifestations of calcium want, such as nervous irritability.

It has been my concept that nephrosis is a relatively benign disease. It occurs in young people. The so-called pure lipid nephrosis that was described by Muller, made known in this country by the work of Epstein of Mount Sinai and then elaborated by the Rockefeller group, shows these characteristic phenomena: prodigious edema—every cavity may have fluid, the face is swollen, severe albuminuria, low plasma proteins, elevated cholesterol, normal blood urea content, absence of hematuria. These patients are treated, as Dr. Mosenthal indicated, with a high protein diet, but their appetite, as a rule, is poor and it is difficult to get them to eat. It is my impression from 1 or 2 cases that I have seen recently that a large dose of vitamin B_1 intravenously two or three times a week or even daily stimulates their appetite somewhat. I have in mind a boy who was here for over ten weeks and who recovered to such a degree that the only indication of the disease was a residual moderate albuminuria, 2 plus or so.

I am much interested in the question of the so-called "dry" and "wet" uremia. I am not entirely clear as to the mechanisms involved and the basis for treatment. Perhaps Dr. Mosenthal can help us out. When an individual is brought to the hospital in uremic coma, as we recognize it from the conventional syndrome, and he is "dry," is it desirable to give fluids by every possible route or will it

tial or the renal variety, has not been satisfactorily accomplished. Specific remedies that hit the bull's eye with even moderate regularity do not exist. The latest of these, potassium thiocyanate, has in my experience not been so completely successful as those who have advocated it have found it to be. However, the devastating reactions that have been attributed to it have failed to materialize when the dosage was guided according to the thiocyanate concentration in the patient's blood.

It is both surprising and gratifying how much can be accomplished for hypertensives by hygienic, physical, and mental adjustments in which selected drug therapy plays a big role. A permanently elevated blood pressure is one of the functional disturbances that is more effectively handled in private practice than in an institution. This does not gainsay that other methods of treatment, especially the discovery and remedying of unilateral renal impairments, are not of the greatest importance, and we live in the hope that the efforts of those investigators who are engaged in preparing a biologic preparation for the control of blood pressure will be successful.

Renal insufficiency, when marked and prolonged, results in uremia and death. The retention of urinary excretory products within the body in the long run causes two sets of symptoms—asthenia and toxic manifestations, ordinarily called retention uremia. We have learned to cope with the latter with a fair degree of success, but the former is still a mystery to us and patients succumb to it.

Anemia—J. R. Bradford in 1899 found that when three-quarters of the kidney substance is extirpated, in dogs, death takes place from asthenia without coma or convulsions. The asthenia is attended in human beings by anemia, which is the constant accompaniment of renal insufficiency whether this is caused by chronic nephritis or other renal or urinary tract impairments. The remedying of anemia in chronic Bright's disease is a major problem since the diminution in the hemoglobin and red blood cells may be a reason for disability and may be a contributing cause to a fatal termination. A high-protein, high-caloric diet will do a great deal in slowing the development of anemia. However, when renal function is severely curtailed it will not prevent the occurrence of anemia or its downward progress. The routine medications for anemia accomplish little. Iron, liver extracts, and vitamins are usually given in the customary fashion. They probably put the brakes on the downhill course, but their slight

effect is disheartening to both patient and doctor.

The really efficacious remedy for the anemia of chronic Bright's disease is transfusion. It must be understood at the outset that transfusions will return the blood count to normal but will accomplish nothing more than this, and any expectation that they will increase renal function or relieve the symptoms of uremia, is not warranted. On the other hand, transfusions produce no harmful effects. They will not elevate the blood pressure and are no more prone to cause reactions in chronic nephritic patients than in other persons. Since transfusions provide the only effective means of rectifying anemia in chronic Bright's disease, it is difficult to see why there has been so much opposition to their use. When the transfusions are used early—that is, before the hemoglobin and red cells are greatly diminished—one will do, but when the anemia has progressed to a point where the hemoglobin is down to a level of 50 per cent or less, then, as a rule, it requires three or four transfusions of 500 to 700 cc each to restore the blood to its normal level. As a rule, the first transfusion or two have no demonstrable effect, while the third and fourth result in a marked rise in the number of red blood cells. Direct transfusions have been much more satisfactory than indirect ones. I have come to appreciate this largely as a result of the demonstrations given me by Dr. Lester Unger.

An interesting case in this connection is one of a boy of high-school age who was the victim of severe chronic nephritis. His anemia was rectified by frequently repeated transfusions carried out by Dr. Lester Unger. Death resulted in an unexpected way. Marked hemorrhages developed rapidly. The blood was vomited and passed in the urine and the stools, and there were many large ecchymoses. The terminal tendency of chronic nephritis to bleed evidently was not prevented by maintaining the hemoglobin and red cells at a normal level.

Retention Uremia—Although the anemia may be considered as part of the effect of retention uremia, the accepted symptoms of actual retention uremia—marked lassitude, nausea, vomiting, coma, and convulsions—come on a long time after the progressive loss of hemoglobin and red cells has begun. Originally, it was thought that the accumulation of all the urinary excretory products, especially the urea, was responsible for the uremic symptoms, but this concept has come to be

and the blood proteins are prone to rise, consequently, the edema will disappear. With that comes the so-called compensatory polyuria, when these patients put out more urine than usual to eliminate the urinary excretory products. The result is that they have the familiar large volume of urine with low specific gravity, and they are then dry—that is, free from edema. Unless there is a complication, they remain dry, if I can call it such, right down to the terminal uremic stage. When they become wet, I believe it is nearly always due to cardiac insufficiency, which may occur in these cases. They are prone to have hypertension. Hypertension dilates the left ventricle and makes it insufficient, consequently, edema may develop. Sometimes you cannot prove this clinically, but digitalis remedies the edema in a great many of these cases.

Concerning ambulatory treatment, I believe it is really the essential way to manage these cases. It is essential for two reasons. In the first place, the disease lasts a long time. In the second place, we want to keep these people at work, like the case Dr Tolstoi mentioned who is now attending some university. All of these cases should be checked at least once in six months, when the urine should be examined for albumin, casts, red cells, and concentrating power. The level of blood urea, the serum proteins, and serum calcium should be determined. The height of the blood pressure and the presence or absence of anemia must also be investigated. That gives us all the phases that should be considered. They vary from time to time, and the treatment has to be changed and adjusted to the symptoms and signs that present themselves at the moment.

As examples of how this plan works out I can mention three cases, all of whom curiously enough began their "nephritic career," in 1931. One boy was the son of a doctor. The boy's brother had died of nephritis. When albumin was found in his urine, his family naturally were apprehensive. He was about 18 at the time. There was albumin in his urine, but he was normal in all other respects. We have checked him about twice a year by the method I have mentioned. About three years ago he developed hematuria. A urologic check-up failed to reveal any reason for the hematuria. The only other change he has had is a slight lowering of his blood proteins, which was remedied when the proteins in his diet were increased, so that he has been perfectly normal except for the albuminuria and hematuria. He is engaged in a business ca-

reer, is married, and has two children, and everything is progressing satisfactorily, although the albuminuria and the hematuria have continued for nine years.

There is another man in whom we first noticed albuminuria about nine years ago. His blood pressure at that time was normal. The albuminuria continued. Hypertension developed in this case, the pressure rose to about 200 or more systolic and 120 or more diastolic, and he died of cerebral complications due to the hypertension eight years after the albuminuria was first noticed. His kidney function was normal. There was no anemia, and no other troubles.

Finally, I have the record of a man who attended Yale University in 1931. He was examined by Dr. Peters at that time and, on several subsequent occasions, had no sign of nephritis except albuminuria. He died in May, 1940, in uremia with a renal insufficiency.

Consequently, the progress of chronic nephritis can proceed along different lines, and each one of them may be a different syndrome though they are all part of the same disease. Too, what is so important, a case may be treated for edema during one six months' period, in the next six months' period the edema disappears, while hypertension becomes the outstanding feature. A year later renal insufficiency may be the dominant factor that has to be controlled. The main point I want to stress is that there is no single formula for the treatment of chronic nephritis. There are various symptom complexes, if we can call them such, and treatment must be adjusted to the symptoms that present themselves.

DR FORKNER. We will now open the meeting to general discussion.

DR C. H. WHEELER. It is my notion that a reciprocal relationship exists between calcium and phosphorus in the blood. Hence, if a patient has phosphate retention as part of renal insufficiency he will develop hypocalcemia and, if phosphate is not increased, hypocalcemia will usually fail to develop. The level of the blood calcium is then more closely related to that of the phosphate than it is to protein, although protein plays a role.

DR MOSENFELT. I think that what Dr. Wheeler says is perfectly true, but my point about this story is that from an empiric point of view we have found that the serum calcium does diminish in cases with albuminuria and the hypocalcemia does produce symptoms. How the phosphorus stands in

suffice merely to control the nervous unrest with sedation and other measures? Would Dr Mosenthal also tell us how to treat an ambulatory case? Consider the case of a man who has "recovered" from acute diffuse glomerulonephritis. We see him two or three months later and find a high albuminuria. Is that to be regarded as the chronic stage of the disease? As you all know, probably 2 per cent of the supposedly normal population have albuminuria, and some of them have even granular casts. Are they really normal, or shall we consider every individual with a high albumin and a few casts as having some type of renal lesion? McLean found during the first World War that among some 70,000 soldiers 5 per 100 had albumin in the urine and about 1 per 1,000 had finely granular or hyaline casts.

For the advanced renal disease, Dr Mosenthal painted a much more hopeful picture than I am inclined to associate with these cases.

DR. FORKNER About twelve years ago I attended a meeting of an association of physicians in Atlantic City, and at that time there was held a symposium on chronic nephritis. Many different points of view were presented, and there was much discussion about the etiology and treatment of chronic nephritis, many individuals feeling strongly about certain points of view and others feeling strongly about other points of view. At the end of the discussion, after two hours or so, Dr William Welch mellowed the discussion by saying that he had heard almost word for word the same discussion about chronic nephritis twenty years before. So I think, although we have made a good deal of progress, there is still much to be learned and much that is still confusing. We will ask Dr Mosenthal if he will answer the questions that have been raised, and then we will go on with other questions from the group.

DR. MOSENTHAL Dr Tolstor's account of the mechanism that brings about the low serum calcium in nephritis follows that of Marriott. I had the good fortune to be with Dr Marriott when he first put out that hypothesis in about 1916 or 1917. But I think there are other reasons for the low calcium than its combination with phosphates and its vicarious elimination by the intestines. Marriott, in the Department of Pediatrics, investigated some of the adult cases I had charge of, and it was fascinating to see his predictions work out. When there was a fairly advanced chronic nephritis or renal insufficiency from any cause such as polycystic kidneys, the blood

phosphates were elevated, the CO_2 combining power was depressed, and the calcium was diminished. The matter, as far as my observations were concerned, rested there until one day about six years ago a child whom I had been treating for nephrosis came into my office showing marked tetany. That child had a low serum calcium, without renal insufficiency and without acidosis. Since then we have been determining the serum calcium in cases of albuminuria, and we found that without acidosis and without renal insufficiency the serum calcium is often diminished and that apparently it produces symptoms that may be quite severe. A case of this sort is that of a dentist who had an albuminuria and a chronic nephritis without impairment of renal function and without any elevation of the blood pressure and who complained particularly of cramps in his hands. That was rather an embarrassing situation to a dentist. With dihydrotachysterol medication the serum calcium rose and at the same time his symptoms disappeared. In nephrosclerosis there is comparatively little albuminuria, and these patients do not develop a hypoproteinemia or hypocalcemia, although they may die of renal insufficiency. Recently, I saw 1 such patient who died of retention uremia with a normal level of serum proteins and a normal value of serum calcium, 10.6 mg per hundred cubic centimeters. Consequently, I am a little bit skeptical about the original explanation of hypocalcemia in renal conditions as the only available explanation. I do think a loss of serum calcium becomes of importance long before acidosis develops in those patients who have a marked albuminuria, though it does not always parallel the degree of hypoproteinemia.

As far as the relation of nephrosis and chronic nephritis is concerned, we have the cases of nephrosis that will follow Epstein's dictum that all these patients get well. I have seen them cured in less than six months after the development of marked hypoproteinemia and marked edema. In some, the albuminuria persists indefinitely in spite of all that can be done, and a great many of them go over into a chronic diffuse glomerulonephritis.

The difference between "dry" and "wet" uremia is, I think, explained on this basis. In the early stages of chronic nephritis there is likely to be the so-called nephrotic component associated with marked edema. As the nephritis persists and the kidney becomes sclerosed, the amount of albumin diminishes in the urine,

because of the humidity I think, on the whole, they do best with the comforts of their home surroundings, provided they are properly protected from the weather when they go outdoors. The ideal experiment would be to set up a series of air-conditioned rooms in which the nephritic patient could live and really see what effects would ensue when the humidity and temperature were carefully controlled.

DR. F. J. HUGHES I should like to ask Dr. Mosenthal to say a word about the control of itching in chronic nephritis, what he does for it, and what explanation is most likely?

DR. MOSENTHAL I don't know the explanation. Lots of people have written about the itching, and I do not think there is any satisfactory answer. It may be that with the compensatory polyuria these patients have they dry out their skin and because of it they have the itching.

DR. FORKNER In patients with bilateral nephritis, with possible pyelonephritis on one side, what are the chances of getting into the difficulty of a renal shutdown through retrograde pyelography?

DR. MOSENTHAL If they have marked renal insufficiency, I think the chances of a shutdown have to be recognized. Patients with hypertension do not endure retrograde pyelography very well. We have not observed any serious setbacks, but we have seen severe reactions in checking these patients by urologic procedures so that, as a result, patients have had to remain in the hospital for three or four days.

DR. WHEELER How about an intravenous pyelogram? Is renal insufficiency a contraindication?

DR. MOSENTHAL When there is marked impairment of renal function, the intravenous pyelogram is a useless procedure. I have not, up to the present, witnessed a severe reaction in connection with intravenous pyelography.

Summary

DR. McKEEN CATTELL In chronic nephritis we have, by definition, a condition in which irreversible changes are present in the kidney, and therapy, therefore, resolves itself into the problem of preventing the disease from progressing and of keeping the patient as fit as possible. The treatment is, thus, almost entirely symptomatic and is directed toward the alleviation of disorders associated with albuminuria, hypertension, and renal insufficiency.

For the *albuminuria* we have no cure, but it is reduced by bed rest. The associated edema is prevented or relieved by a high protein diet—up to 200 Gm. or more per day. Beef serum, egg white, beef muscle, beef liver, and casein have all been shown to be effective. Gelatin is without value, and transfusions as a rule do not help. The salt intake should be restricted, but limitation of the fluid intake is regarded as of secondary importance. The elimination of fluid is promoted by diuretics, and one of the most useful of these is urea, which in the absence of elevated blood levels may be given in doses of 10 Gm. three times a day. When the edema is advanced and crippling, recourse is had to the mercurial diuretics, which are recommended despite diseased kidneys. Their effect can be enhanced by the use of acid salts, which are employed only when necessary.

The mechanism of the *hypocalcemia* frequently observed in chronic nephritis was discussed and the association with high blood phosphorus and depleted albumin levels was noted, but no agreement was reached as to the primary cause. The remedy is replacement therapy or calcium by mouth or, in emergencies, by vein. Dihydroxycholesterol by mouth is also efficacious.

The symptoms of *uremia* may to a large extent be controlled by the prevention of hypocalcemia, acidosis, and excessive chloride retention.

For *hypertension* we have no specific treatment, but a great deal can be accomplished by attention to general hygiene, including both physical and mental aspects. Thiocyanate was the only form of drug therapy mentioned as having possible value.

As the disease progresses an *anemia* tends to develop, an occurrence that may be delayed by a high protein, high caloric diet. While routine anemia therapy (iron, liver, and vitamins) is usually instituted, it accomplishes but little. Repeated transfusions are efficacious in raising the blood count and improving the general condition of the patient, but they do not improve renal function or relieve the symptoms of uremia.

In general, it is recommended that few, if any, restrictions be placed on ordinary activity, diet, or fluid intake. The important matter in the management of patients with chronic Bright's disease is meticulous care in symptomatic treatment, by which means we may prolong life and maintain these patients as active and useful citizens until the terminal stages of the disease.

all of these cases I do not know, but I am certain that the calcium will diminish without there being any acidosis of note. It is purely from the practical therapeutic point of view that we have pursued this subject thus far and have found that we could relieve many disagreeable symptoms by attending to the calcium deficiency.

DR OSCAR BODANSKY I think it ought to be mentioned in respect to the blood calcium, phosphorus, and protein that formulas have been devised by Peters and by Greenwald showing that there is a relationship among the three of them—the calcium content varies inversely as the phosphorus and directly as the protein. When these three are taken into account the agreement of findings is usually, but not always, pretty good—that is, the blood chemistry findings are in accord with these formulas.

DR HARRY GOLD I should like to ask Dr Mosenthal if he would say a few words about the matter of diet in nephritis. Is there any virtue in the restriction of the meat intake or the protein intake in any case of chronic nephritis? Is there any merit in the suggestion of putting patients on an acid-ash diet in nephritis with edema? Also, should fluids necessarily be restricted in a patient with nephritis and edema, or do these patients do better even though they have a good deal of edema if one allows a liberal supply of water—let us say, 1½ L or even 2 L a day? One further question, does physical rest play an important part in the maintenance of renal function? There are experiments showing that violent physical exercise has the tendency to depress renal function and reduce the clearance tests. These have been made with normal athletes. I wonder whether a person with a borderline renal insufficiency might not precipitate serious renal failure by walking about a good deal or by engaging in other physical activities. Is there any experience in regard to this matter?

DR MOSENTHAL About twenty-five years ago Von Norden dominated the treatment of all the so-called diseases of metabolism. He advocated a prolonged lactovegetarian diet whenever albuminuria occurred. The conception was that albuminuria signified renal insufficiency, and we all accepted it. That was before we had a test for renal function except the specific gravity in casual specimens of urine. Then Rowntree and Geraghty's phenolsulfonephthalein test came into being, and we discovered, much to our amazement, that a person could have albumin in the urine

while the kidney function was apparently normal. Twenty-five years ago we began with fear and trepidation to feed a high protein diet to patients with albuminuria. We were gratified to learn that this remedied their anemia, increased their vigor and failed to raise their blood pressure or diminish their renal function. This practice has continued, and a few years ago we fed a high protein diet to all patients until the blood urea nitrogen rose as high as 40, then as high as 60 and, today, contrary to what I think some others would do, I allow nephritic patients to have all the meat and fish and eggs they want until the end of their days. As I have watched the situation, I think that is the proper method to pursue. As far as the acid-ash diet is concerned, we do know that an acidosis promotes diuresis, but whether we have not become overenthusiastic in this regard is an open question. At the Post-Graduate Hospital I was shown a severe acidosis resulting from the routine administration of ammonium chloride.

The idea of giving fluids in the presence of edema is based on the fact that it is not the fluid intake that results in the retention of water and edema, but it is the sodium. Fluid can be taken in reasonable amounts without causing an increase in the edema provided sodium salts are rigidly restricted. Somebody was telling me only a few days ago that the cardiologists in the treatment of cardiac failure were doing the same thing—giving water without salt and giving it freely.

The questions of physical rest and exercise influencing the clearance tests can well be considered together. In 1915 I saw a medical student with albuminuria, and I had the idea at that time that if a person had albuminuria he should be put up in cotton batting and a glass case and looked at once in a while to see how he felt. This young man had been a patient of Dr Christian's and I corresponded with Dr Christian about him. He said, "Why don't you let him go ahead and do his work? His albuminuria is going to pursue the same course whether he is active or whether he is not." Ever since then I have encouraged these patients to lead normal lives as far as possible. The results have been gratifying because life becomes worth living, and the fortunate optimism that chronic nephritic patients have right down to the very end can express itself.

DR TOLSTOI Would you care to say something about climate?

DR. MOSENTHAL I think Florida is a poor climate for nephritic and cardiac patients.

The business meeting with the election of officers was in the morning, and members of the Association were guests of the hospital at a luncheon. Later, Dr Harris addressed the group and gave a demonstration on vitamin complex.

Sound motion pictures depicting the work of Dr Tom Spies, of Hillman Hospital, Birmingham, Alabama, were shown through the courtesy of Squibb and Company.

Members of the county association from Hudson and every town in Columbia County attended the annual session. The group meets twice each year, and the next meeting is scheduled to be held during the summer of 1942.

Erne County

Dr Joseph C O'Gorman, chairman of the publicity, education, and speakers' supply committee, reports that Thursday, November 13, has been designated as the "Fall Clinical Day and Fifty-Year Dinner," which will be held in the Hotel Statler, Buffalo.

The afternoon will be devoted to a scientific program by three nationally outstanding members of the profession. Following this will be a "refreshment and get-acquainted hour," and the evening will be devoted to honoring the forty-odd members who have practiced medicine for fifty years or more.

The meeting of the Buffalo Academy of Medicine on October 29 was devoted to the general practitioners who comprise the majority of the physicians practicing in Erne County. Three local physicians each presented subjects of specific interest to the general practitioner, including rectal conditions, the new sulfa drugs, and varicose veins.

The Regional Maternal Welfare Teaching Day was held at the University of Buffalo Medical School on October 16. It was presented under the auspices of the Maternal Welfare committees of Erie, Niagara, Chautauqua, Cattaraugus, Genesee, and Wyoming county medical societies, the University of Buffalo School of Medicine, the Division of Maternity, Infancy and Child Hygiene of the New York State Department of Health, and the Medical Society of the State of New York.

The program was "Maternal Mortality Investigation in Buffalo," by Dr Louis A. Siegel, "Treatment of the Toxemias of Pregnancy," by Dr Francis C Goldsborough, "Diagnosis and Treatment of Bleeding in the Third Trimester," by Dr Herbert Burwig, "Treatment of Post-Partum Hemorrhage," by Dr Hugh C McDowell, "Technique of Breech Extraction," by Dr Milton G Potter, and "Forceps Technique," by Dr Edward G Winkler.

Dr Walter S Goodale, superintendent of the Edward J Meyer Memorial Hospital, died of a heart attack on October 8 at his home in Buffalo. He was 66 years old. Among the policies that Dr Goodale inaugurated and which commanded national attention were the establishment of a special division of communicable diseases within the hospital, full-time services in the medical, surgery, and laboratory departments, and a department of surgical research and the development at the hospital of the physical therapy department and alcoholic and psychiatric wards.

Greene County

Dr R. Reudemann, Jr, of Albany, was the guest speaker at the annual meeting of the county society which was held on October 14 in the Memorial Hospital in Catskill. His subject was "The Diagnosis and Management of the More Common Skin Diseases in General Practice."

Dr Herbert F Weinauer, delivered the annual presidential address and the election of officers was held.

Dr Herbert Weinauer, president of the county society, explained why he is in favor of the public health nursing project at the meeting of the supervisors on October 13, in compliance with a resolution passed by the Greene County Tuberculosis and Public Health Association at their last meeting. They requested him to speak on the project from his own practical experience.

Miss Clara Marciano, public health nurse, has been serving a population of approximately 5,000 persons in Windham, Ashland, Prattsville, and Durham, giving a service such as the association is proposing for the county, with each nurse living in and serving a community of that size.

If Greene County will appropriate \$4,059, the State Department of Health will match this fund with another \$4,059, then Greene County can employ three public health nurses. In order to have the county adequately covered with public health nurses, the State Department of Health will place two more nurses there without any additional expense to the county.

Figures presented at the meeting showing costs of tuberculosis cases not discovered early enough for early cure demonstrated the saving in human values and taxes when an adequate program of prevention, treatment, and cure is carried out by public health nurses in cooperation with the doctors.

Jefferson County

At the regular monthly meeting of the county society held on October 9 at the Black River Valley Club in Watertown, Dr William W Hall discussed "The Present Status of Diabetes." Dr Frederic R. Calkins, president, presided at the meeting, which was attended by 45 members and which was preceded by a dinner.

Kings County

The Kings County and South Brooklyn Medical societies are collaborating with the Health Department in a community experiment that stresses the control and cure of tuberculosis in the early stages of the disease.

A section of South Brooklyn has been temporarily designated as the grounds for the experimental project which will start early in December.

Outlining tentative plans for the experiment at a meeting of the Tuberculosis Sanatorium Conference of Metropolitan New York at the Kings County Hospital, Dr Alfred E. Shipley, emeritus professor of preventive medicine of Long Island College of Medicine, said that a letter will be prepared under the joint heading of both medical societies and will be sent to doctors in the South Brooklyn area.

The doctors, in turn, will urge their patients and friends to come in for x-ray examinations.

Medical News

Speakers on Chemotherapy Available to Medical Groups

IN THE October 15 issue there was an editorial on the recent conference held in Albany on the use of the sulfonamides in the treatment of disease. The program of the meeting, which was attended by thirteen experts on chemotherapy from some of the larger medical centers throughout the East, is printed below. County societies and other medical groups that may wish it can have a course dealing with every aspect of the chemotherapy of sulfonamides arranged for them through the Council Committee on Public Health and Education.

The program of October 7 and 8 at Albany was as follows

Chemistry, absorption, distribution, conjugation, and excretion of sulfonamides

E K Marshall, M D
Baltimore

Action of sulfonamides on bacteria and role of immunity in the response to chemotherapy

Colin MacLeod, M D
New York City

The approved laboratory in New York State in relation to chemotherapy

John K Miller, M D
Albany, New York

Modes of administration and preparation of solutions

W Barry Wood, Jr, M D
Baltimore

Toxicity and follow-up of patients

Maxwell Finland, M D
Boston

Submission of written questions from the floor
Round-table discussion

William S McCann, M D
Rochester, New York

The clinical use of gramicidin and penicillin

Chester S Keefer, M D
Boston

Pneumonia

Norman Plummer, M D
New York City

Gonorrhea

C J Van Slyke, M D
Washington, D C

Infections of the urinary tract

E P Alyea, M D
Durham, North Carolina

Sulfonamides in surgery—local and general use

John S Lockwood, M D
Philadelphia

Use of sulfonamides in pediatrics

Benjamin W Carey, M D
Pearl River, New York

Treatment of meningitis

John H. Dingle, M D
Boston

Submission of written questions from the floor
Round-table Discussion

George M Mackenzie, M D
Cooperstown, New York

County News

Broome County

At the regular meeting of the society, held October 14 in the auditorium of City Hospital in Binghamton, the society decided to enroll in the Council of Social Agencies of Broome County for the coming year. It was reported at the meeting that a new tuberculosis clinic had been opened by the State Department of Health in Binghamton, Dr E R. Dickson to be in charge. This step was taken as a result of studies made by the Tuberculosis Conference Committee, set up last year by the State Department of Health, with representatives from the State Charities Aid Association, the State Medical Society, the Metropolitan Life Insurance Company, and the New York State Department of Mental Hygiene.

After the regular meeting Dr Peter Irving, secretary of the State Society, addressed the members. He reviewed the activities of the State Society in general, stressing in particular certain efforts to solve present urgent problems. One of these is the revision of the school health program. Dr Irving also asked that experiences of the members with "direct payments" for medical care under the categories of relief to the aged, blind, and dependent children be reported to the county society committee as well as to the local health officer for reference after the period of observation is over.

Cattaraugus County

Dr J Lous Preston, of Salamanca, died on October 3 from injuries received in an airplane accident a few days before. Dr Preston was 52 years old. Active in civic, as well as medical, organizations, he was one of the founders of the Western New York Hospital Service Corporation and a member of its board of managers, he was also one of the organizers of the Western New York Medical Plan, representing the county society on its board of managers. He was a past-president of the society and had practiced medicine in Salamanca for twenty-one years.

Columbia County

Dr Ralph S Spencer, Hudson surgeon, was elected president of the county society at the annual meeting of the organization held October 7 at the Hudson City Hospital. The meeting was presided over by Dr R. P Harris, retiring president.

Other officers elected were vice-president—Dr Cecil L. Schultz, of Philmont, secretary-treasurer—Dr Henry C Galster, Hudson, re-elected, delegate to the New York State convention—Dr John L. Edwards, Hudson, censors—Dr Clark G Rossman, Dr R. P Harris, Hudson, Dr Frank C Maxon, Chatham, Dr Henry J Noerling, Valatie, and Dr Leonard Carpenter, Germantown.

Rockland County

The fall meeting of the county society was held at the Letchworth Village, Thiells, New York, on September 24.

The speaker of the afternoon was Dr. Morris Kellogg Smith, F.A.C.S., attending surgeon at St. Luke's and New York hospitals. Dr. Smith delivered a most interesting talk on "The Medical and Surgical Treatment of Thyroid Disease."

Following the scientific session and adjournment of the meeting, the members retired to the dining room where a collation was greatly enjoyed.—*William J. Ryan, M.D., Secretary*

St. Lawrence County

Members of the county society held their annual dinner meeting at the Arlington Inn, Potsdam, on October 9. A business and scientific session followed the dinner.

Dr. W. J. Baldwin, of Potsdam, was elected president to succeed Dr. U. R. Plante. Other officers chosen were Dr. F. E. Clark, Ogdensburg, vice-president, Dr. Robert Reynolds and Dr. J. McNulty, both of Potsdam, re-elected secretary and treasurer, Dr. M. J. Stearns, Ogdensburg, Dr. Frederick Mason, Massena, and Dr. Robert Reynolds, censors.

Retiring President Plante spoke on "Acne-bulgaris," skin disease, as part of the program.

Seneca County

The members of the county society were guests of the staff of the Willard State Hospital for their annual meeting October 2.

At this meeting the fee for home calls was increased from \$2.00 to a minimum of \$2.50 and the fee for office calls was raised from \$1.00 to a minimum of \$1.50.

An amendment to the bylaws was introduced to reduce the number of yearly meetings from ten to four.

Dr. K. S. Landauer, of Geneva, showed some pictures and held an interesting bull session on "Diagnosis and Treatment of Allergic Diseases."

To take office January 1 are the following: president, Dr. G. M. Brandt, Seneca Falls, vice-president, Dr. R. E. Wallace, Seneca Falls, secretary-treasurer, Dr. D. B. Walker, Waterloo, delegate to State Society, Dr. Arthur Baldwin, Waterloo, alternate delegate, Dr. G. M. Brandt, Seneca Falls, delegate to Seventh District Branch, Dr. A. Letellier, Seneca Falls, and alternate delegate, Dr. J. E. Allen, Seneca Falls.

The Public Health Committee of the county society, through its chairman, Dr. Duane B. Walker, has organized a series of clinics to cover every village and town in the county. Dr. Don Griswold, district health officer, warns that "with the advent of cold weather, communicable disease may make its appearance and it is part of good judgment for every citizen, migrant worker, and resident alike to be immunized as far as possible."

Schenectady County

The county society held a symposium on cancer at a meeting in the auditorium of Nurses' Home, Ellis Hospital, October 7.

Members of the society who spoke and their subjects include: Dr. Arthur Q. Fenta, "Carcinoma of the Larynx, a Case Presentation," Dr.

C. L. Morave, "Primary Carcinoma of the Gall-Bladder," Dr. W. M. Brown, "Gastric Cancer," Dr. F. F. McGauley, "Carcinoma of the Large Intestine," Dr. J. M. Blake, "Cancer of the Lung," Dr. H. L. Traenkle, "Treatment of Cancer of the Skin," and Dr. C. M. Zava, "Medical Care for the Advanced Cancer Patient."

Schenen County

Members of the county society are being given a course of lectures on traumatic surgery at Bath. The lectures are given by surgical men of New York City, sponsored by the Council Committee on Public Health and Education of the State Medical Society.

The two remaining lectures in the series are November 6, "Treatment of Femur and Humerus Fractures," W. D. Ludlum, Jr., New York City, November 13, "Nerve and Tendon Injuries," Ernest Lampe, New York City.

Suffolk County

The Suffolk County Tuberculosis and Public Health Association celebrated its twenty-first birthday on September 25 at the Patchogue Hotel.

The celebration was the occasion for the presentation by the association to Dr. William H. Ross, of Brentwood, first president of the association, of a citation for public service. The citation was presented by Surrogate Richard W. Hawkins, who praised Dr. Ross for his "far-sighted leadership and unselfish service."

Among those present were the three men who first proposed the establishing of the Suffolk Sanatorium before the Suffolk Medical Society in 1912. These were Dr. Ross, Dr. Frank Overton, of Patchogue, and George Nelbach, executive secretary of the Tuberculosis Division of the State Charities Aid Association. Of the 6 original officers 4 were present and of 19 original directors 8 were present.

Sullivan County

The following lectures conclude a pediatrics series that began October 15. November 5, "Rheumatic Fever and Heart Disease" at Workmen's Circle Sanatorium, Liberty, New York, by Dr. Albert D. Kaiser, associate professor of pediatrics, Rochester University School of Medicine, November 12, "Polio-myelitis—Practical Suggestions in the Treatment and Care of a Polio-myelitis Case" at Monticello Hospital, Monticello, New York, by Dr. Francis Carr, New York City, November 19, "The New York State Program for the Rehabilitation of Handicapped Children" at Lenape Hotel, Liberty, New York, by Dr. Francis Carr, New York City, and November 26, "Infectious Diseases of Childhood" at the home of Dr. Harry Golembe, 111 Champlain Avenue, Liberty, New York, by Dr. A. C. Silverman, professor of clinical pediatrics, Syracuse University College of Medicine.

Tioga County

Dr. John B. Schamel, of Waverly, has been nominated for the presidency of the county society. Officers will be elected in December.

Others nominated are as follows: vice-presi-

and then report their findings to a central headquarters

The annual meeting of the Brooklyn Urological Society will be held on Monday evening, November 10, 1941, at 9 00 P M at the Kings County Medical Society Building

The guest speaker will be Dr Leon Herman, of Philadelphia, professor of urology in the Graduate School of Medicine of the University of Pennsylvania. He will discuss "Difficult and Obscure Urological Problems"

Monroe County

The county society, the University of Rochester Medical School, and the Education Committee of the State Medical Society are cooperating this year for the first time in sponsoring a Postgraduate Institute on November 11, 12, and 13 (See page 2164 for the complete program.)

New York County

Dr James Frederick Rogers and Dr Haven Emerson were honored at a testimonial dinner at the American School Health Association Convention held in Atlantic City on October 13

Dr Louis Faugeres Bishop died at his home in New York City on October 6 Dr Bishop, who was 77 years old, had practiced medicine in New York City for over forty years Since 1908 he had devoted his time entirely to diseases of the heart and blood vessels

Dr Eugene F DuBois, retiring as physician-in-chief of the New York Hospital and professor of medicine at Cornell Medical College, was honored by 250 physicians at a dinner at the Waldorf-Astoria in New York City on October 9 Dr DuBois, an authority on metabolism, is continuing as professor of physiology at the college

The American Social Hygiene Association arranged a dinner on October 11 to mark the thirtieth anniversary of the announcement of the discovery of salvarsan by Dr Paul Ehrlich Mrs Ehrlich was the guest of honor on this occasion. Among the speakers was Dr Thomas Parran, Surgeon General of the U S Public Health Service

Nassau County

Nassau County is in a singularly vulnerable position if trouble should start, says the *Nassau Medical News* It contains vital defense industries of considerable magnitude, it is the home of Mitchel Field But more than that Nassau County is on the direct line of flight to New York City from any point to the East Nassau must be prepared to care for its own casualties

The Office of the State Director of Civilian Defense in New York State, through Major General John F O'Ryan, recently addressed a question to the Nassau County Defense Council asking whether the hospitals of Nassau County had on hand reserve medical stores for a possible 1,500 casualties in one day

The Nassau County Medical Society sees five vital steps necessary in the care of civilian casualties first, there must be medical men immediately available at the scene of the disaster, second, these doctors must have adequate materials and supplies made available to them when they arrive, third, transportation to hos-

pitals must be provided for the more seriously injured, fourth, doctors must be at the hospital to take care of these patients when they are brought in, finally, the hospitals must have immediately available the reserve medical stores needed in an emergency

The society has completed its plan whereby doctors would be available at once both at the scene of disaster and at the hospitals. The other three steps must be taken by other official and voluntary agencies

Oneida County

The regular monthly meeting of the county society was held on October 14 at the Oneida County Hospital in Rome. Luncheon was followed by this scientific program "Carcinoma of the Penis," by Dr John Fitzgerald, "Appendicitis from Pin Worms", by Dr W Theodore Wheeler, interesting case reports and general discussion Dr J B Lawler, president, presided.

Onondaga County

Dr Garrison L Brown has just completed sixty years of practice in Euclid. Eighty-seven last June, Dr Brown is still going strong according to the *Syracuse Herald* of October 5 Dr Brown is the oldest active member of the Onondaga Medical Society and one of its first presidents a half century ago

"Examining the Town" in a recent *Onondaga Bulletin* carried the following paragraph

"One of the busiest men during the summer months was O W H. Mitchell arranging many an important meeting under the guidance of the New York State Medical Society Only a few can fully appreciate what he has done in this capacity"

During October the following broadcasts were arranged by the medical society "The School Child and Its Health" by Dr Ralph R. Scobey on October 3, "Burns" by Dr Leonard M Aquilino on October 10, "The M D and National Defense" by Dr Edward S Van Duyn on October 17, "Kidney Stones" by Dr Ephraim J Goldman on October 24, and "Anemia" by Dr Ellery G Allen on October 31

Ontario County

The regular fourth quarterly meeting of the county society was held at the Canandaigua Hotel on October 14.

The business meeting preceded the dinner after which there was a scientific session. A talk was given on "Diseases of the Skin—in Color," by Dr Leon H. Griggs, associate professor of dermatology, Syracuse University

Otsego County

The regular quarterly meeting of the Otsego County Medical Society was held on September 24, at the Hotel Oneonta in Oneonta. Preliminary steps were taken to recommend a medical adviser, chosen from society members, to act as go-between for practicing physicians and the County Welfare Department in the handling of indigent patients At the scientific session, a paper, illustrated by lantern slides, was given by Dr John Latcher, of Oneonta, on the subject "Endometriosis."

Hospital News

Hospital Bed Facilities in the U S A.

THE most widespread survey ever made of hospital bed facilities in the United States reveals that 1,282,785 beds were available in 9,614 institutions for the medical care of the American people in 1939, according to a September release by the Census Bureau of the Department of Commerce.

The country's 6,991 hospitals and sanatoriums provided the great bulk of this care—355,145,063 patient-days or the equivalent of one weekend stay in a hospital each year for every person in the United States. Infirmarys and nursing, convalescent, and rest homes provided the remainder.

Hospitals and sanatoriums had 1,186,262 beds—92 per cent of the nation's total. Census Bureau figures show that the average hospital had 169 beds and served 5,000 families.

Hospital facilities for the country, however, were well below the "minimum requirements for adequate medical service" set up in 1933 by the Committee on the Costs of Medical Care. Here's how the number of hospital beds per 10,000 population compares:

	Beds Available	Beds Needed
General	38	46
Tuberculosis	6	14
Mental	46	56
Total	90	116

To meet this minimum of 116 beds per 10,000 population, the United States would have to build 2,000 more average-size, 170-bed hospitals.

Even counting in all the beds available in infirmarys and nursing, convalescent, and rest homes, the Census figures show that twenty-six states had inadequate hospital facilities—fewer than 100 beds per 10,000 population. Eighteen states had between 100 and 124 beds—approximately adequate facilities. Massachusetts, New York, Colorado, Maryland, and the District of Columbia had good facilities—more than 124 beds per 10,000 population. New York State alone had 192,345 medical-care beds—more than one-seventh of the nation's total.

Even existing facilities are not being used fully, the Census Bureau Survey indicated. Allowing a margin of reserve for epidemic peaks, the Committee on the Cost of Medical Care estimated that general hospitals would operate most efficiently with an occupancy of 80 per cent, mental and tuberculosis hospitals, with an occupancy of 90 per cent.

In 1939, general hospitals were operating at 70 per cent of capacity, tuberculosis hospitals at 85 per cent, and mental hospitals at 95 per cent. The Census Bureau noted that many mental hospitals are overcrowded because of rapidly increasing hospitalization for this type of illness. Although only 594 hospitals—less than 1 in 10—were for nervous and mental patients, they had 602,850 beds—more than one-half of the total for all types of patient.

Approximately 77 per cent of the care rendered in 1939 was in state, local, and federal govern-

ment-controlled hospitals, 20 per cent in non-profit institutions, and 3 per cent in proprietary institutions, the Census Bureau noted.

Average Stay per Patient in General Hospitals, 1940

AS PART of the exhibit of the American Medical Association at the Cleveland meeting in June there was a chart showing the average stay per patient in general hospitals in 1940 according to the types of hospitals involved, says the Nassau County *Bulletin*.

	Days
Government Hospitals	
Federal	31 3
County	19 4
State	18 1
City	15 6
City-County	15 0
Non Proprietary	
Association	10 7
Church	10 5
Proprietary	
Corporation	8 7
Individual and Partnership	7 8

Newsy Notes

Dr Robert E. Plunkett, of Troy, general superintendent of the tuberculosis hospitals of the state, has been named by the Republic of Colombia as consultant in the construction of a new tuberculosis hospital in that country.

Dr Plunkett will assist the architect designing the building in working out details and in finding a suitable location for the structure. Colombia is the fourth South American country to receive Dr Plunkett's aid in their efforts to fight tuberculosis. Other countries he has aided are Bolivia, Dominican Republic, and Argentina.

• • •

E. W. Jones, director of Albany Hospital and president of the Hospital Association of Northeastern New York, in an address before the Massachusetts Hospital Association at Pittsfield on October 3, said that his experience has shown him that hospitals are "the least understood by the general public of all our social, health, business, industrial, or public utility organizations."

He added that hospitals can tell their story through cooperative relations with local newspapers, telling the hospital's story to the civic, social, and church organizations, and by urging hospital employees to help improve public relations. Constant contact with the community is essential, he said.

"The hospital that maintains an aloof, secretive attitude, refusing to tell its story and to cooperate with all agencies, will become a mysterious, fearsome place from which people shrink," he remarked.

ADVANTAGES OF COUNTY SOCIETY MEMBERSHIP

The Special Committee on New Members of the New York County Society sums up the advantages of membership admirably in a recent report as follows

The strength of the profession lies in its solidarity and fellowship. Membership in the society has many varied advantages and values, both professional and educational. It gives professional prestige, you have the assurance of ethical standing and professional responsibility to the public, the law, and the profession.

In addition to serving the educational needs of the doctor, the Medical Society of the County of New York engages in a wide range of advisory service in collaboration with members of the municipal, state and federal, and welfare organizations on various aspects of public health and welfare

It affords active membership in the Medical Society of the State of New York and the American Medical Association, it offers admission and participation in annual meetings of the state and national societies, it cooperates in the giving of refresher courses and graduate study courses, and at the same time gives the members an opportunity to express their viewpoint and aid in directing organized medical activities. You get the benefit of your officers and committeemen working for a common interest, collectively solving

problems impossible of solution by individual physicians

You receive the *New York Medical Week*, the *Medical Directory*, the semi-monthly scientific publication, *THE NEW YORK STATE JOURNAL OF MEDICINE*, an opportunity to obtain group health and accident insurance at a very reduced rate, and the right to free legal defense and low cost indemnity insurance against malpractice claims.

You have individual service and protection in Workmen's Compensation cases, you have protection for yourself and your patients in exposing charlatans, fraudulent schemes, and illegal practitioners through local enforcement agencies and other legal contacts of medicine.

Membership in your county society is necessary for certification by the national specialty qualifying boards, many hospitals require county society membership for staff appointment.

It goes without saying in these trying times that the profession belongs together as a unified body of ladies and gentlemen, able, willing, and cooperative with one another to such a degree that the cost of participation in the New York County Medical Society membership is a privilege and a duty which must and will pay its dividends by an enlightened and healthy community furnishing high type medical standards.

We invite your immediate attention for your own and our own good

"At the menopause 80 per cent of women experience general symptoms of varying character and intensity¹."

AMNIOTIN

Relieves
Menopausal
Symptoms

JEFFCOATE,¹ in a paper on estrogenic hormone therapy, states that 80 per cent of women experience menopausal symptoms varying from the well-recognized vasomotor disturbances to those of vaguer character such as headaches, emotional instability, depression, anxiety and muscle pains. In a large percentage of cases these symptoms can be eliminated by adequate estrogenic therapy.

During the more than 10 years in which Amniotin has been available to the medical profession its clinical effectiveness in controlling menopausal symptoms has been abundantly demonstrated.

It differs from estrogenic substances containing or derived from a single crystalline factor in that it contains, in highly purified form, estrogenic substances naturally present in pregnant mare's urine. Its estrogenic activity is expressed in terms of the equivalent of international units of estrone.

Amniotin is available in Capsules containing the equivalent of 1000, 2000 and 4000 I U of estrone, in Pessaries containing 1000 and 2000 I U and in 1-cc ampuls containing 2000, 5000, 10,000 and 20,000 I U.

A SQUIBB PREPARATION OF ESTROGENIC SUBSTANCES
OBTAINED FROM THE URINE OF PREGNANT MARES

Dr John D Stewart, member of the surgical staff of the Massachusetts General Hospital and of the faculty of Harvard Medical School, has accepted the position of full-time surgeon-in-chief of the Edward J Meyer Memorial Hospital at Buffalo and professor of surgery in the University of Buffalo Medical School

sentent with a modern, fully equipped iron lung by the Orange County Chapter of the National Foundation for Infantile Paralysis

To prevent the landlord from taking over operation of Yonkers Professional Hospital, the institution's board of directors has agreed to a higher rent schedule and will assume responsibility for whatever deficit may result from increased rent, Dr John A. Faiella, board president, disclosed on October 3

Work will soon begin on a new two and one-half story dispensary building at Cumberland Hospital, Auburn Place and North Elliott Place, Brooklyn. The foundation will be strong enough to add two more stories when sufficient funds are allotted for their construction

The dedication ceremonies of the new \$700,-000 Hillside Hospital, were held on October 19. The site of the mental hospital is at 263rd Street and Union Turnpike, Queens, Long Island.

Originally, the Hillside Hospital was located in Hastings and the directors had asked the Village Board for permission to build an additional wing to the property which was located just above Reynolds Field.

With the refusal of the Board to grant such authority, because of Village zoning laws, the hospital was moved from Hastings last year

Hospital Plan, Inc., has remodeled a building at 5 Hopper Street, Utica, for the exclusive use of the nonprofit hospital and cooperating medical plan. Hospital Plan, Inc., one of the first of 63 similar plans in the United States to be officially approved by the American Hospital Association, has adopted the Blue Cross as its emblem and, in cooperation with sixty-seven other Blue Cross plans, exchanges information and transfers enrollments and hospitalization cases

Dr Vincent Haight, of Buchanan, has been unanimously elected president of the Medical Board of the Peekskill Hospital to succeed Dr B R. Lowery whose term has expired. The consulting staff and the courtesy staff of the Peekskill Hospital were reappointed

Other officers elected were vice-president, Dr Nathaniel Blumenkranz, secretary, Dr Leo V Feichtner (re-elected), treasurer, Dr Willard W Sweet, Jr (re-elected), executive officer, Dr Theodore Trousdale, Supervisory Committee Dr Nathaniel Blumenkranz, Dr Frederick Rauch, and Dr Hyman Millman (re-elected)

The Tubercular Pavilion at Riverside Hospital' the Bronx, will not be completed this year because of material shortage, it is announced by Dr John G Grimley, deputy commissioner of hospitals. The project was one of eight city improvements given high priority ratings by the OPM, and all the steel needed for the framework of the \$1,000,000 hospital structure has been delivered. But additional steel for elevators, stairways, etc., must be obtained on the basis of priority rating that places it secondary to government needs

Sixteen hundred babies have been born at Monticello Hospital since it opened in 1923. A dollar contribution to the hospital for each of these babies was the aim of Philip Kaplan, chairman of the arrangement committee for the annual hospital banquet.

Improvements

A new emergency ward for men in the C and D Pavilion of Bellevue Hospital in New York City was opened on October 2 by Dr William F Jacobs, medical superintendent of the hospital. The ward is equipped with all modern fixtures, including indirect lighting, and has a capacity of 24 beds. There is a balcony from which physicians and nurses can look down on the entire ward

The new \$200,000 addition to the Brooks Memorial Hospital in Dunkirk will be opened to the public in the early part of December. The new building is the first of two similar wings planned to complete the new hospital plant

Metal laundry chutes, which will convey all the soiled clothing and linens (12 tons daily) of 3,600 inmates directly to washing and cleaning apparatus, will be installed by WPA, among other features incorporated in a \$207,500 Presidential-approved project. The project also involves 1,300,000 square feet of interior and exterior painting and the replacement of obsolete plumbing features including old galvanized water lines in all buildings, which cover 28 acres between Albany and Utica avenues.

According to Dr Clarence H Bellinger, superintendent in charge, the residential population of the Brooklyn Hospital has increased since 1936 from 1,250 patients to 3,600 patients

St. Luke's Hospital in Newburgh has been pre-

Defense priorities have occasioned the delay in the completion of the new addition to the Leonard Hospital in Troy, which was to have been opened September 1. The addition will probably not be ready before December

"SEE YOUR DOCTOR!" Reproduced below is Number 171 of a series of full-page advertisements published by Parke, Davis & Co. in the interest of the medical profession. This "See Your Doctor" campaign has been running in *The Saturday Evening Post* and other leading magazines for thirteen years

The man who nearly died . . . from a few kind words

BYOND THAT DOOR lies a very sick man. True, his doctor says he is going to pull through. But he has come mighty close to paying a tragic price for a few words of free advice from a well-meaning friend.

When he complained of a nagging pain in his abdomen, his friend said "You've probably eaten something that's poisoned you. Here's what I'd do . . ."

So he promptly followed his friend's suggestion and took a cathartic. And in a matter of hours he was being rushed by ambulance to the hospital with a ruptured appendix.

His friend, of course, had acted from the kindest of motives. But he didn't know that an abdominal pain might mean acute appendicitis, in which case a cathartic should never be taken.

Unfortunately appendicitis is only one of many illnesses where amateur medical advice can result in tragedy. Yet, human nature being what it is, many people just can't resist the temptation to offer advice when a friend is sick.

Intelligent medical treatment depends upon various factors which only a physician is qualified to evaluate. When something

seems wrong with you, it is the part of wisdom to observe this common-sense rule: Take a friend's advice about buying a radio, a car, or even a home if you wish; but don't let him advise you about your health.

Don't let a friend who means well tell you how to get well. To get well, and keep well, the man to see is your physician.

PHYSIOLOGIC ANTISEPSIS WITH **ARGYROL**

NO CILIARY INJURY

DECONGESTION WITHOUT VASOCONSTRICTION

DETERGENT AND DEMULCENT

NO PULMONARY COMPLICATIONS

NO SYSTEMIC TOXICITY

Safe and Effective Mucous Membrane Therapy

The ability to kill micro-organisms is but one of many factors which determine the clinical efficacy of a mucous membrane antiseptic.

It is because ARGYROL impedes bacterial life without injuring the tissues, because it aids and does not impede those natural defensive processes which the tissues employ to throw off infection, and because it is non-noxious to the organism as a whole, that ARGYROL is truly a "physiologic mucous membrane antiseptic."

ARGYROL effects a decongestion through circulatory stimulation and without resorting to powerful artificial vasoconstriction. Because of its unique physical properties it is detergent,

demulcent, and inflammation-dispelling. But it is non-injurious to the cilia—whose vital role in overcoming upper respiratory infections has been repeatedly pointed out. ARGYROL remains equally bland and non-irritating to the tissues in all concentrations from 1% to 50%, and it is free from the dangers of systemic toxicity and pulmonary complications.

ARGYROL has a superior clinical record to all other mild silver proteins and it is chemically and physically different—in colloidal dispersion, in Brownian movement, in pH and pAg and in chemical reactions. Insist on the Original ARGYROL Package.

REGIONAL MATERNAL WELFARE TEACHING DAY

Nassau and Suffolk Counties

THE Maternal Welfare Teaching Day will be held at the Nassau Hospital in Mineola, New York, on Thursday, November 13. Dr Arthur C Martin, of Hempstead, is chairman of the local committee on arrangements. Other committee members are Drs L J Barber, W W Gardner, and George Bergman from Suffolk, and Drs A F Calvein and R L Jones from Nassau.

The event is sponsored by the Long Island College of Medicine and is presented under the auspices of the Department of Obstetrics and Gynecology, the Long Island College Hospital, Maternal Welfare committees of the Nassau and Suffolk County Medical societies, the Division of Maternity, Infancy and Child Hygiene, New York State Department of Health, and the Medical Society of the State of New York.

The meeting will be called to order at 1 30 p.m. by Dr Harvey B Matthews, regional chairman, Maternal Welfare Committee, Medical Society, State of New York, who will introduce Dr George Borden Granger, chairman, Maternal Welfare Committee, Nassau County Medical Society, Dr Leon J Barber, chairman, Maternal Welfare Committee, Suffolk County Medical Society, and Dr Arthur C Martin, chairman, Local Committee on Arrangements.

2 00 P M Demonstration of a Maternal Welfare Conference Procedure, Dr Charles A. Gordon, Brooklyn, professor of clinical obstetrics and gynecology, Long Island College of Medicine (Kings County Division)

Hemorrhage Associated with Pregnancy

2 30 P M 1 Bleeding During the Early Period of Pregnancy, Dr Vincent P Mazza, instructor in obstetrics and gynecology, Long Island College of Medicine.

2 50 P M 2 Bleeding During the Last Trimester of Pregnancy, Dr Mervyn V Armstrong, assistant clinical professor in obstetrics and gynecology, Long Island College of Medicine

3 10 P M 3 Postpartum Hemorrhage, Dr Morris Glass, assistant clinical

professor in obstetrics and gynecology, Long Island College of Medicine

3 30 P M The Toxemias of Pregnancy, Dr Frank P Light, instructor in obstetrics and gynecology, Long Island College of Medicine.

Exhibits and Demonstrations

1 Postgraduate Education in New York State, Dr O W H Mitchell, Syracuse, New York, chairman, Council Committee on Public Health and Medical Education, Medical Society of the State of New York.

2 Shock (Experimental data, graphs, charts, illustrations, photographs, etc), Dr Erich Ponder

3 The Blood Plasma Bank, Dr T J Curphey and Dr J Wesley Bulmer

4 Obstetrical Pathology, Dr T J Curphey

Adjournment to Garden City Hotel

A social hour will be held at 5 30 p.m. followed by a dinner meeting at 6 30 p.m. The speaker will be Dr Alfred C Beck, professor of obstetrics and gynecology, Long Island College of Medicine. His subject will be "How Can the Obstetrician Aid in Reducing the Mortality of the Prematurely Born Infant?" The discussion will be opened by Dr Minor Hill, followed by a general discussion and/or questions.

The price of the dinner is \$4 00 plus 40¢ new Federal Tax, including cocktails and gratuities. No other fees will be charged. Dress—Informal. The Committee on Arrangements must know how many plan to attend the afternoon session and how many will be at the dinner. Reservations should be addressed to

Committee on Arrangements

ARTHUR C MARTIN, M D, chairman,

Hempstead, L I

The car had come to a sudden standstill on a country road. The motorist descended, diagnosed the trouble, and then applied at a neighboring cottage for assistance.

"Pardon me," he said to the old woman who answered his knock, "do you by chance possess any lubricating oil?"

The old woman shook her head.

"Any oil will do," said the motorist, hopefully, "castor oil if you have any."

"I ain't got it," said the old woman, regretfully, "but I could fix you up with a bit of salts."

—Kablegram

The publicizing of a biological discovery before the matter has been fought out in expert conclave is not only stupid but in many cases is cruel by reason of the false hopes it arouses and the vain expenditures of money and effort it imposes on those who may be misled. To be just to the scientists themselves, it may be said that the most serious delinquencies of this kind committed in our country in the last decade or so must be laid at the doors of administrators and directors impelled by desire for institutional advertising.—Hans Zinsser in *As I Remember Him*

Perplexities IN PROVIDING SUFFICIENT VITAMIN B *complex*

Planning of diets which provide sufficient amounts of the factors comprising vitamin B complex presents certain difficulties. The quantitative distribution in foods has been rather accurately determined for some of the factors, but regarding others much must still be learned. Moreover, there is an appreciable loss of water soluble factors during cooking.

In view of these and other perplexities, the synthesis and concentration of the various factors of the vitamin B complex group assume particular importance.

Betaplexin—vitamin B complex—is available in several forms. Variations in dosage are made readily and individual tastes are easily satisfied.

Workmen's Compensation

September 15, 1941

Concerning Physicians Making out Employer's C-2 Report of Accident

Some time ago the propriety of a physician's preparing the C-2 report for an employer was questioned. An opinion was requested of the Industrial Commissioner as to the propriety of this procedure. Under date of September 9, 1941, the following ruling has been received from the Department of Labor:

"Dear Dr. Kaliski:

"This is in reply to your letter of July 23rd in the above matter.

"In this instance the insurance carrier complained that the employer's report, our form C-2, was made out by the claimant's attending physician and submitted to the employer's bookkeeper. I have delayed in replying to this matter in order to give it second thought.

"Technically, it would appear that the employer has complied with Section 110 of the Workmen's Compensation Law since the form was signed by a person in his employ designated to perform this function. On the other hand, it was obviously the intent of the Workmen's Compensation Law to have the information required by the Industrial Commissioner corrected and fully supplied. It is conceivable that the practice complained of may deprive the Department of Labor of information as to the circumstances of the accident or injury. *It is therefore in the interest of justice that authorized physicians be advised that it is not their business to prepare reports which the law requires employers to file.*

Very truly yours,

RALPH R. BOYER, Director,
Division of Workmen's Compensation"

Authorized physicians are, therefore, requested to desist from this practice in the future. The form C-2 must be made out, signed, and filed by the employer. It would not be improper for a physician, reporting a claim, to request the employer to file the C-2 form promptly with the Department of Labor and carrier, but it is not the physician's duty or right to make out the form and submit it to the employer for his signature.

DAVID J. KALISKI, M D, Director

Announcement of Van Meter Prize Award

The American Association for the Study of Goiter again offers the Van Meter Prize Award of \$300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The Award will be made at the annual meeting of the Association which will be held at Atlanta, Georgia, June 1, 2, and 3, providing essays of sufficient merit are presented in competition.

The competing essays may cover either clinical or research investigations, should not exceed 3,000 words in length, must be presented in English, and a typewritten, double spaced copy must be sent to the corresponding secretary, Dr. T. C. Davison, 478 Peachtree Street, Atlanta, Georgia, not later than April 1.

The Committee who will review the manuscripts is composed of men well qualified to judge the merits of the competing essays. Dr. Asher Chapman, of Rochester, Minnesota, received the Award for the year 1941 in recognition of his essay entitled "The Relationship of the Thyroid and the Pituitary Glands to Iodine Metabolism and Extrathyroid Iodine Metabolism."

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author if it is possible for him to attend. The essay will be published in the annual *Proceedings* of the Association. This will not prevent its further publication, however, in any journal selected by the author.

Woman's Auxiliary

To the Medical Society of the State of New York

THE fall executive board meeting of the State Auxiliary was held at Auburn, September 30 and October 1. It was a splendid meeting, with good attendance, 44 members were present. Twenty-two county presidents answered the roll call. Mrs. George B. Adams, state president, welcomed the visitors on their arrival at her home. A delicious dinner was given at the Owasco Country Club on Tuesday evening. The Cayuga County Auxiliary was hostess to the visiting board members. Guests were entertained in private homes and at the Springside Inn on Owasco Lake. On Wednesday the business meeting was held at Springside Inn, Mrs. George B. Adams graciously presiding. She extended greetings to all present, especially to the three new county presidents. Reports of all state officers, chairmen of committees, and county presidents were read and accepted. These reports evidenced an increase in membership and continued interest in the varied activities of the Auxiliary. We are honored to have in our group Mrs. John L. Bauer, the first president of the State Auxiliary and now first national vice-president. Mrs. Carlton F. Potter, first vice-president of the State Auxiliary, is a director on the National Board.

Mrs. Henry F. Pohlman, convention chairman, announced the New York State Medical Convention, which will be held in New York City at the Waldorf-Astoria on April 27, 28, 29, 30, 1942. Mrs. Alfred Madden is planning to have the county legislative chairmen visit a legislative session. Mrs. Carlton E. Wertz is striving for more members and for more county auxiliaries. Mrs. Louis A. Van Kleeck brought good news from the Physicians' Home. All of the guests have received a remembrance on their birthday. Mrs. G. Scott Towne is taking subscriptions for the *Bulletin*, and Mrs. Albert M. Bell presented many ideas for program material.

The board members are indebted to Mrs. George B. Adams and to the Cayuga County Auxiliary members for their generous hospitality and their splendid entertainment.

Mrs. Luther H. Kice, junior president and now serving as a director, has been appointed chairman of the Nassau County Mental Hygiene Committee.

On Program

"The Doctor's Wife in Defense" is the title of an article in the postconvention issue of the *Bulletin* of the Woman's Auxiliary to the American Medical Association. This article outlines a broad program of activity for state and county auxiliaries by means of fourteen well-thought-out procedures, beginning with the all-important admonition, "do nothing without the approval of your local advisory council," and continuing on current health problems, the study of nutrition, first aid, mental hygiene, and legislation.

As our programs are the tools with which we build the structure of an active organization,

we should make sure that we fully understand the use of these instruments. Tastes differ and what interests one member keenly, another feels not worth spending time on. Therefore, we must recognize all three types of program—educational, social, and economic. The value of a planned program, printed if possible and distributed to the membership at the beginning of the year, will be noticeable in the increased attendance at meetings.

In planning the program for any auxiliary the chairman and her committee should work closely with the committee on public health and public relations. These supply material for many interesting programs, and the public health services in the state are always ready to assist by suggesting topics and speakers.

Health has been called our nation's "first line of defense." In these serious days we Auxiliary members have an opportunity to take our places alongside the members of the medical profession, interpreting to the general public the full meaning and proper maintenance of fine physical and mental health. Let us determine to serve our country both in peacetime and in wartime. If the need arises, let us be fully equipped physically, mentally, and spiritually.

Mrs. ALBERT M. BELL

County News

Columbia. Mrs. George B. Adams, state president, was a guest at a luncheon, held at Rainbow's End, Valatie, on October 21, followed by a business meeting and social hour.

Jefferson. The opening meeting of the auxiliary was held at the Black River Valley Club, with Miss Marjorie Starkweather, Y. W. C. A. representative of the U. S. O., as the speaker. The wives of all medical officers at Pine Camp and Madison Barracks were invited.

Nassau. On November 25 the regular meeting of the auxiliary will be held at the Nassau Hospital Auditorium at 8:45 P. M. Dr. Legrand Kerr, of Brooklyn, will speak on "Dames, Doctors, and Doings in the Drab Nineties."

Onondaga. The Auxiliary was happy to be given the opportunity of assisting in the plans for the luncheon given the members of Fifth District Branch held in the Terrace Room of Hotel Syracuse on September 23. Mrs. Leo E. Gibson was general chairman and was assisted by the following committee chairmen: Mrs. John Buettner and Mrs. Edward C. Reifenstein, hospitality; Mrs. Charles D. Post, luncheon; Mrs. John J. Hogan, tickets; and Mrs. Marcus D. Richards, entertainment.

A clever playlet, written by Mrs. Marcus Richards, was enacted by Mrs. Francis R. Irving, Mrs. Brooks McCuen, Mrs. Carlton F. Potter, Mrs. Tom Walsh, Mrs. Gerald Cooney, Mrs. Glendon Lewis, Mrs. Walter W. Street, Mrs. Henry H. Haft, Mrs. Albert Garofalo, Mrs. J. J. Derr, Mrs. Truman Wilcox, Mrs. John Hogan, Mrs. Neil Paul, Mrs. Herman L. Harding, Mrs. Joseph Delmonico, and Mrs. B. F. Colegrove.

THE WAR ECONOMY

To date, comparatively speaking, war economies have not affected the daily existence of the average person. The full force of non-defense curtailments and priorities has not as yet created any serious hardships. But, unless the seemingly impossible at this moment occurs soon, there will come a day when we will all be faced with the problem of obtaining some of the necessities of life and business.

True, it becomes increasingly difficult to get materials and finished products without great delays in deliveries, but actually there is no shortage of things that are really necessary. The problem, as it now stands, is to anticipate our wants and requirements far enough in advance to assure receiving things by or before the time they are needed.

Mounting costs also suggest the advisability of order-

ing an ample quantity as far in advance as may be practical. While the government in good faith may be trying to prevent war profiteering in every field, in the face of mounting taxes it is inconceivable that such efforts can be wholly successful.

For those who have some used equipment to sell, now is the time to offer it for sale. The difficulty of obtaining new equipment and the higher prices, makes this period an opportune time to dispense with things at a profit that may no longer be required by, or useful to, an individual.

The classified columns of this JOURNAL provides an excellent contact with thousands of your colleagues each issue. The cost of a few lines is small, and you can never tell without trying whether or not a colleague would be interested in the item you have to sell.

TERRACE HOUSE for ALCOHOLISM

A private sanitarium offering a specific treatment for alcoholism formulated to relieve the craving for alcohol and with re-education working toward permanent abstinence. Homelike surroundings. Competent medical and nursing care. 16 miles from Buffalo.

Moderate rates—Enquiries invited

64 Maple St. - East Aurora, N. Y. - Phone 784

Physician in Charge

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 2170]

Mrs. Edgar M. Neptune, the auxiliary president, greeted the guests and introduced the play.

The first fall meeting of the auxiliary was held at the Nurses' Recreation Hall of St Joseph's Hospital on October 7. Mrs. Grace Saunders, supervisor of cafeterias in the city schools, discussed nutrition and its effects. She described the breakfasts being served undernourished children in our community.

Mrs. DeAlton Ridings, president of the Woman's Auxiliary to the Syracuse Free Dispensary, outlined the work of the Dispensary, describing numerous ways in which our organization could assist that institution. We are outlining our work for the year now and this Dispensary is one of the fields we are hoping to work in. We will continue our collection of surgical equipment for Bundles for Britain and the Red Cross.

Mrs. Charles DeMong was chairman of the hostess committee for the evening, with Mrs. Frederick S. Wetherell and Mrs. Gerald Cooney as co-chairmen, assisted by Mrs. Albert Swift, Mrs. Brooks McCuen, Mrs. George L. Wright, Mrs. John Buettner, Mrs. Eugene N. Boudreau, Mrs. Dwight V. Needham, Mrs. Neal Conan, Mrs. Louis G. Fournier, Mrs. V. G. Van Ornam, Mrs. Francis Rosenberger, Mrs. George Raus, Mrs. William Pelow, Mrs. Thomas Walsh, Mrs. Raymond J. Devine, and Mrs. Joseph Thornton.

Oswego Members of the auxiliary opened their season with a luncheon at Hotel Pontiac, with Mrs. Harold F. McGovern, of Fulton, president, presiding. Plans were formulated for cooperating with Dr. Harwood L. Hollis, superintendent of the Oswego County Sanatorium at Orwell, in an effort to control tuberculosis. All boys and girls participating in athletics in high schools of the county are to be examined before being on teams. Plans were made for a fashion show to be held at the Pontiac Hotel on November 13.

Queens The Defense Health Forum, held at

the Medical Society Building on October 22, was an outstanding success. Dr. Thomas D'Angelo introduced the following speakers: Dr. Herbert R. Edwards, who spoke in the absence of Dr. John L. Rice, Dr. H. V. Z. Hyde, medical officer, Second Defense Area, Dr. Luvia Willard, chairman of American Women's Hospital Corps, and Dr. H. P. Menken, chairman, Medical Preparedness. A film, "In Defense of the Nation," was shown through the courtesy of Mr. Charles Freck, executive director of the Queensboro Tuberculosis and Health Association.

The first regular meeting was held on October 28, with Mrs. Michael M. Schultz, president, presiding. The speaker for the evening was Mrs. Elsie Stapleton, from Gimbel Brothers, whose topic was "Fun on a Budget." She was introduced by Mrs. William Lavelle, chairman of the program.

The Fall Dinner-Dance will be held November 15 at Hotel Pierre, Fifth Avenue, New York City. Mrs. Edward Veprosky will be in charge.

The Red Cross surgical groups and first-aid classes are still doing splendid work. Mrs. Thomas D'Angelo is in charge.

Warren On the motion of Mrs. E. B. Jenks, of the Bolton Road, the auxiliary voted at a meeting that all members collect physicians' discarded instruments and drug samples to be sent to the hospitals in Great Britain. Mrs. Leonard A. Hulsebosch reported on the executive board meeting held in Auburn. Plans for the fall were outlined in keeping with the purpose of the organization—to create closer cooperation in the community between the medical profession and the various civic and service groups. Emphasis will be placed on public health and nutrition and hygiene in connection with the community welfare, and work is being done for such groups as the American Red Cross and other service organizations. The meeting closed with a social hour and refreshments.

NEW YORK STATE SOCIETY OF PATHOLOGISTS

The annual meeting of the New York State Society of Pathologists was held on October 4 at the De Witt Clinton Hotel in Albany.

The following amendment to the Constitution of the Society was presented and carried unanimously: "that the Annual Meeting of the Society be changed to the place and date preceding the Annual Convention of the Medical Society of the State of New York, the specific time to be decided by the Executive Council."

The following officers were elected: president, Dr. Ward H. Cook, vice-president, Dr. Ward J. MacNeal, secretary-treasurer, Dr. M. J. Fein, Dr. Ralph Stillman and Dr. Walter S. Thomas were nominated and elected councillors to the American Society of Clinical Pathologists.

Dr. Ward H. Cook, chairman, has appointed a committee composed of Drs. Dalldorf, Marten, and MacNeal to join with the New York State Association of Public Health Laboratories to recommend the replacing of the coroner system by Medical Examiners.

"PETROLAGAR" CHANGED TO "PETROGALAR"

A change in the spelling of the name "Petrolagar" to "Petrogalar" has been announced by the Petrogalar Laboratories. The change is being made in both the product name and corporate name.

Company officials, while pointing out that the adoption of the new spelling does not affect the formula or quality of the product in any way, said that they considered the change advisable to avoid any possible misconception as to the nature of the product.

"Because it has never been the intention of the company to imply that agar-agar was used for any other purpose than as an emulsifying agent, the last syllable of the former name has been altered in favor of the new spelling," officials said.

Officials emphasized that no change has been made in the size of the package, price, or formulas and that each of the five different types of the product will carry the new spelling "Petrogalar." The new corporate name is Petrogalar Laboratories, Inc.

WARTIME LITERATURE

Salute, a new magazine published by the British War Relief Society, discusses in one of its articles the merits of literature in wartime.

"The criticism of books written during wartime," declares the publication, "must be concerned with the traditional problem of whether or not great writing can be achieved under the stress of great emotion."

While the article agrees that war conditions do stimulate creative ability, it feels that the emotions aroused are likely to be conflicting and violent, and, that there is inevitably a lack of perspective in writing about a war while bombs fall about the writer.

"For these reasons," remarks the author, citing *All Quiet on the Western Front* as an example, "prose classics are likely to flower long after the war that inspired them." Poetry, however, fares differently and some of lasting value was composed during the last war within battle areas.

A second branch of writing that also flourishes in wartime is that of speeches, and for just one verification of this fact we need only to recall the immortal address of our own Civil War President at Gettysburg. Eng-

land's man of the hour has created speeches "that fill two noble volumes."

The most successful literature in wartime, according to this article, must deal with the thoughts and feelings of real people—not imaginary ones, and the novelist finds it difficult to create characters and invent situations stirring enough to drag us away from our newspapers. "Personal affairs seem a little trivial and fictitious tragedies tend to dwindle against a background so awesome and exciting as the real scene today."

The author of the article in *Salute* believes it idle to attempt to prove that a wartime book (especially one penned during a current war) is great or not, but expresses the opinion that such literature does have a particular quality, a merit of its own, particularly one that gives us an idea of what people think while they are fighting a war.

Sums up the author—"All that is written later in 'tranquility,' however classic, cannot give us the first impact, the immediate reaction. It is sure to be touched by afterthoughts and later interpretations, just as books about childhood by adults can never quite recall a child's feelings."

"NO SHOWS" IN AIR TRANSPORTATION

Several serious problems face the nation's air transport companies these days, and the one that baffles them most is a solution to the "No Show" problem.

In the parlance of air transportation, "No Shows" are passengers who make reservations and then fail to appear for the flight. As a service to passengers, reservations are held right up to actual time of departure, and if the passenger is not on hand the plane must leave with the seat unoccupied.

The bad feature of this practice is the inconvenience it causes others who could have taken the plane. An empty seat might have been filled by a businessman on an urgent defense mission, or by an engineer rushing to a military post, or by a surgeon racing to an emergency operation. When flights are booked solid, it is rare when a seat reserved for a "No Show" could not have been filled by someone racing against time. And time is important to America today.

Thousands of businessmen, government officials, military leaders, and technical experts are dependent upon our fastest mode of travel, while the air lines must adhere to higher standards than before in spite of having their fleets depleted by the demands for military craft. Eliminating the "No Show" waste can help air liners and the general public alike.

If a reservation is cancelled the minute a person knows he or she cannot make the trip, the seat can be used by another passenger whose mission may be just as urgent, or more so.

So if you are scheduled to fly at any time and something urgent causes a change of plans, make some attempt to notify the air line, even if it gives them only a few minutes to replace you as a passenger. There are often others who must make a last minute decision to fly and your cancellation will provide them the opportunity they might otherwise miss.

WARTIME LITERATURE

Salute, a new magazine published by the British War Relief Society, discusses in one of its articles the merits of literature in wartime.

"The criticism of books written during wartime," declares the publication, "must be concerned with the traditional problem of whether or not great writing can be achieved under the stress of great emotion."

While the article agrees that war conditions do stimulate creative ability, it feels that the emotions aroused are likely to be conflicting and violent, and, that there is inevitably a lack of perspective in writing about a war while bombs fall about the writer.

"For these reasons," remarks the author, citing *All Quiet on the Western Front* as an example, "prose classics are likely to flower long after the war that inspired them." Poetry, however, fares differently and some of lasting value was composed during the last war within battle areas.

A second branch of writing that also flourishes in wartime is that of speeches, and for just one verification of this fact we need only to recall the immortal address of our own Civil War President at Gettysburg. Eng-

land's man of the hour has created speeches "that fill two noble volumes."

The most successful literature in wartime, according to this article, must deal with the thoughts and feelings of real people—not imaginary ones, and the novelist finds it difficult to create characters and invent situations stirring enough to drag us away from our newspapers. "Personal affairs seem a little trivial and fictitious tragedies tend to dwindle against a background so awesome and exciting as the real scene today."

The author of the article in *Salute* believes it idle to attempt to prove that a wartime book (especially one penned during a current war) is great or not, but expresses the opinion that such literature does have a particular quality, a merit of its own, particularly one that gives us an idea of what people think while they are fighting a war.

Sums up the author—"All that is written later in 'tranquillity,' however classic, cannot give us the first impact, the immediate reaction. It is sure to be touched by after-thoughts and later interpretations, just as books about childhood by adults can never quite recall a child's feelings."

Editorial

The Bitter Fruit

It has come to pass that as this is written small groups of willful men are openly defying the authority of government in these United States on a question that has nothing to do with the preservation of human rights, at a time of grave peril, when the civil liberties of everyone in the nation will have to be abridged temporarily for the common safety.

The rebellion of this musled group follows by a little more than a month (September 17) the dramatic power strike in Kansas City which plunged 400,000 people into darkness and terror, and a mere six months after the strike of maids, orderlies, employees in the nurses' home, the engineering division, and the garages of the West Penn Hospital.

Why should medicine take editorial cognizance of these strikes? Because, at this writing, Mr John L. Lewis and Mr Westbrook Pegler's well-named "union-eers" have the power, if they wish to do so, to tie up this country's entire defense program unless they get just what they want. Furthermore, if they have no hesitation or compunction about doing this, how much less would they hesitate to disorganize the country's hospitals, ambulance services, and power supplies. This has, in fact, been demonstrated in the Kansas City outrage.

The extent to which the auxiliary services of the hospitals have already been unionized is not generally appreciated. The extent of communist infiltration of

the technical services of hospitals is also not generally known. It has been assumed that institutions of this humanitarian character would be immune from threats to, or attacks upon, the welfare of the sick, the maimed, and the dying.

Apparently, the assumption is without basis in fact. Apparently, the temper of Mr Westbrook Pegler's "union-eers" is such that they do not and will not concede the immunity of the Nation's defense program or the safety of its sick, maimed, and dying from ruthless, cynical, and at times violent, attack. There is little to be anticipated from public authority, seemingly, beyond the soft word. The entire legislative structure, both federal and state, respecting labor has been, and now is, set up in a manner which, in operation, encourages the exploitation of the defenseless, both in the hospitals and throughout the Nation.

This fact is of grave concern at least to medicine, for much of medicine's ability to function effectively and efficiently in our so-called industrial civilization is dependent upon the continuity of services that lie within the domain of labor. The right of labor to strike does not in our view of constitutional liberties include the right to strike at the welfare of the helpless or to hold them as hostages to the settlement of jurisdictional disputes and irresponsible rapacity.

For the healthy to have to eat the bitter

fruit of unwise government policy toward industrial problems is bad enough, but that the sick, the maimed, and the dying should be compelled in their helplessness to have to eat it too, and to wash it down with the sour wine of their impotence in

darkness, in terror, in fear, is the last insult of a truly decadent way of life.

Is there no courage in our legislators which, in the name of God, will place the necessities of the sick above the loss of a few votes?

The Missionary Spirit

The American Association for Social Security, which is sponsoring a "health insurance"¹ bill introduced in Washington by Senator Capper, is ably represented by Mr Abraham Epstein, its executive secretary

Mr Epstein now, as in the past, is engaged in selling government "health insurance," federal and/or state. It is his life's work. He gets around. On October 10, 1941, he got around to the convention of the New York State Osteopathic Society. There he spoke. Said he, in part "It is fortunate that the leadership of the New York State Osteopathic Society has had the vision, *still lacking in the New York State Medical Society*,² to realize that constructive programs of social action along the lines of providing medical care can only help the physicians as well as the nation. To continue to ignore the problem of sickness when it is known that it is the greatest cause of poverty, is social negligence bordering on the criminal. It is obviously suicidal to permit our people to go without adequate medical care merely because they cannot afford to buy such care individually and unaided."

The Medical Society of the State of New York will doubtless be gratified to learn that Mr Epstein has reserved, if he has been correctly reported, a place in his commodious doghouse not only for the Medical Society but for the United States Treasury as well. He is said³ to have charged "the medical profession with blocking extension to its field of the social security program," and "attacked the United States Treasury Department on

the ground that it thought of the existing social security set up in terms of revenues rather than benefits"

Mr Epstein, though not yet so colorful, is rapidly acquiring the technic of salesmanship long exemplified by Mr Harold Ickes. We shall probably hear more of him as time goes on. He is selling an idea—government "health insurance"—which more and more people are inclined to think of as a *sickness tax*. It may be that this aspect of the matter accounts for the reluctance of the Medical Society of the State of New York to embrace Mr Epstein's current and past enthusiasm. The Society is not interested in sales campaigns. It is concerned now, as in the past, not with the peregrine promotion of a government sickness tax but with workable and forthright plans to provide the best possible medical service to the greatest number of people. The Medical Society of the State of New York has the vision, still lacking in diverse nonmedical groups regrettably, to see that before the best medical service can be made widely available to the public it is necessary to have a sufficient quantity of the best kind of doctors to provide it.

The possession of a certain amount of vision, in the evangelical meaning of the word, need not blind anyone to practical, common, or horse sense. The world cannot get along without the evangel. His enthusiasm, his energy, his penetration of far places, his unflagging endurance and, in the case of the urban evangel, his iron digestive tract capable of withstanding the continual assault of dinner after hotel dinner compel the admiration of lesser clods. And yet

¹ Sickness tax. Ed.

² Italics ours. Ed.

³ New York Times, October 11 1941

There remains the necessity to deal with cold, hard, inescapable fact. It is often wearisome, we admit, and unsensational. But it is our business. Our "constructive program of social action" consists, first, in assuring to the people of the state the largest number possible of thoroughly trained, well-educated physicians and, second, in providing the means and the opportunity for keeping them well informed by a state-wide program of post-graduate education. At the moment, a large proportion of the younger members of the profession are serving the government. The remainder are caring for the medical needs of the civilian population in the only way that has yet proved to be practical—namely, by painstaking attention to one case at a time, day after day. Prosaic, but practical.

True, all this has to be paid for. Physicians, like anyone else must have some means of support, even in this pleasant Utopia in which as a Nation we have attempted to isolate ourselves. Something for nothing is still comparable to perpetual motion in fact, if not in sales talks. That is probably why the United States Treasury Department, which Mr. Epstein execrates, has finally found its way into his doghouse. It must think in terms of revenues before it can begin to

think in terms of benefits, being charged with the financing of a social security program.

It occurs to us that, beginning now, a great many people are commencing to worry, not about the certainty of ultimate death but about the certainty of proximate taxes. This same hard-boiled attitude of the Treasury Department, so obnoxious to the evangelical Mr. Epstein—namely, the securing of adequate revenues—will be reflected in the citizen-taxpayer's 1942 tax bills, in his pay envelope, in the hidden levies on everything he needs.

Mr. Epstein's task of selling a government sickness tax¹ now to a citizenry already faced with a one hundred billion dollar debt, increasing at the rate of ten billions a year, to a citizenry now faced with enormous taxes and surtaxes, to a citizenry now awakening to the fact that such a government sickness tax⁴ could only be administered by a huge, expensive bureaucracy of still more tax eaters makes the job comparable to that which the *New York Times* itself has undertaken in a similar evangelical spirit. We do not see eye to eye with Mr. Epstein, but we recognize courage when we see it, even if it be the valor of enthusiasm.

¹ Often referred to as Health Insurance.

Rehabilitation

On October 10, 1941, the President announced plans for "rehabilitating 200,000 of the 1,000,000 youths who have been rejected for military service because of physical or mental deficiencies."¹

This plan has been adopted on the basis of a report to the President made by Brigadier General Hershey, director of the Selective Service System. It is a workable plan. It has been in operation as a pilot experiment in the Second Corps Area under the direction of Colonel Arthur McDermott, director of Selective Service for New York City, and under the supervision of Colonel Samuel J.

Kopetzky. It follows sound principles. It has adhered to facts and has been designed in such a way as to bring to light certain basic data about which, to date, little has been known and much has been asserted.

The program "will apply immediately to the 200,000 who were certified by local draft boards as susceptible of physical rehabilitation for the Army. Local physicians and dentists will give the treatments, for which the Federal Government will pay as part of the cost of national defense."¹

We are of the opinion that this is the proper approach to an eventual improve-

¹ *New York Times* October 11 1941 p. 1

ment in the national thinking as well as the national well-being. It has been made possible by an emergency which produced the Selective Service System, a realistic application of the democratic process, free from political considerations and concerned solely with the common safety. As such, the program must be supported wholeheartedly by the medical profession and should be given every encouragement by the public.

It involves a concept difficult for the man on the street to grasp unless it is presented simply and unless it is kept simple and straightforward. Of this concept Dr S J Kopetzky² said "Educational campaigns are not enough to make the obvious remedy to solve the problem practical. The concept that every citizen has an obligation to perform his military duty should be strengthened. A law

which makes it compulsory for the citizen to perform a year's duty in the armed forces of the country should be broadened to prevent remediable defects from deterring men from carrying out this obligation of citizenship." Later, on August 15, 1941, the Commission on Physical Rehabilitation, headed by Dr George Baehr of Columbia University, recommended to Mr Paul V McNutt, Federal Security Administrator, a government-financed program of voluntary physical rehabilitation of rejected selectees. Of this recommended plan Mr McNutt said, in part "While the program is directed primarily toward making more men available for military service, it has far greater implications for the future public health of the country, particularly in relation to the opportunities for the replacement of these registrants into civilian pursuits after the emergency is over."

This is common sense, it is the kind of hardheaded thinking which, simply stated, should appeal to the man on the

street. It is something he can understand, devoid of political or emotional obliquity. It is fair. The government contributes something, the physicians contribute something, the public contributes something. The public safety is secured and the public well-being is enhanced.

It seems to us unfortunate that in its write-up the *Times*¹ should have chosen to state in the subhead of the article "President Tells Rehabilitation Plan and Says Our Health Conditions Indict America." It seems to be true that Mr Roosevelt said "he considered the existence of the conditions revealed by the Selective Service examinations as an indictment of America." A little farther on, the news story states "Of those rejected under the Selective Service Act, 100,000 were found mentally unequipped for service, since they did not have the equivalent of a fourth-grade education."

Just how this is related to our health conditions is not clear. It is not explained. It does not appear to be related to the rehabilitation program. It is further stated "Of the approximately one million rejected, 900,000, or about 90 per cent, were found to be physically or mentally unfit." But it is seen that on the breakdown of the figures 57,000, or 6.3 per cent only, were rejected for mental and nervous diseases per se. The larger number, 100,000, were rejected because of insufficient educational equipment or educational capacity, aside from any question of mental disease or other physical handicap.

Because of the apparent irrelevancy of these figures and the false impression they tend to create, we repeat that it is unfortunate in our view that they should have been, so to speak, dragged in by the ears to becloud the straightforward issue of the rehabilitation of about 200,000 men with assorted but remediable mental or physical defects.

¹ Kopetzky, S J. New York State J Med. 41 No. 14, 1487 (July 15) 1941.

THE SIGNIFICANCE OF MUSCULAR BALANCE IN ACUTE DISORDERS OF POSTURE AND LOCOMOTION*

HENRY H JORDAN, M D , New York City

THE significance of pathologic conditions of the musculature in acute disorders of posture and locomotion has not been sufficiently recognized. In a considerable number of so-called minor ailments, seen in everyday practice by physical therapists as well as by orthopaedic surgeons, the purely muscular nature of the pathologic condition is often not diagnosed. Consequently, the treatment may not be the most efficient and the rehabilitation of the patient is either delayed or not achieved. Then, patients belonging in this group frequently turn for help to osteopaths or even chiropractors. It is exactly in the conditions to be discussed in this paper that manipulative treatment by an osteopath is often successful, casting an unfavorable reflection on the medical profession. It seems, therefore, timely to analyze and discuss acute disorders of locomotion and posture caused by disturbance of the physiologic balance between agonists and antagonists or between bilateral synergists. These conditions, if properly diagnosed, would yield readily to our treatment, as a matter of fact, these are most gratifying cases for both specialties, orthopaedics and physical therapy.

A classic example of such an acute muscular disorder is represented by the so-called spastic or rigid pronated flat foot, with its characteristic sequence of events.

A patient comes to the office walking with a marked limp and complaining of severe pain on weight-bearing in one foot. He states that he has had occasional foot trouble and that he has previously tried various types of foot plates and orthopaedic shoes with more or less success. But today, while going down the subway steps, he apparently turned his foot and, since then, has had severe pain that made weight-bearing almost impossible. Examina-

tion shows no symptoms of an acute trauma, no swelling, and no discoloration indicating hematoma. While the unaffected foot presents a moderate degree of pes plano valgus, freely movable in all directions, the painful foot is completely rigid in a position of supination. Active movements of the foot in the direction of pronation and supination are impossible, while a certain degree of dorsiflexion and plantar flexion may still be present. An attempt at passive motion of the foot from the position of extreme supination to normal alignment and pronation fails. The foot is so stiff that bony ankylosis is simulated. The metatarsus follows the tarsus rigidly into marked supination and cannot be pronated. In the upright posture the first metatarsal bone and the great toe do not touch the ground. Weight is borne on the heel and the outer border of the foot only. The tendons of the tibialis anticus and tibialis posticus muscles are conspicuously prominent. These muscles are maximally contracted, they are hard and painful. Pain in the foot may be so severe as to suggest an acute inflammation. Apart from the pain, however, the other classic symptoms of inflammation are absent. Roentgen examination may be completely negative, especially in younger patients. X-rays may, on the other hand, show osteoarthritic changes, for instance, in the region of the scaphoid or the first metatarsophalangeal joint. On the basis of such x-ray findings the acute painful condition may be diagnosed as arthritis, misleading for treatment.

Let us analyze what has actually happened to this foot. For months or years both feet have been in plano valgus position—that is in faulty static alignment with regard to the center axis of gravity in standing and walking. In the upright posture, for instance, the plumbline from the center of the hip joint through the center of the knee joint and of the ankle joint did not hit the ground through the center of the heel as is normal.* The valgus position places the heel laterally to the center axis of gravity. This faulty static alignment, which presents itself in innumerable cases, is mechanically unsound. The body weight is not properly supported by those elements of the foot which are built to take up the axial

Read at the Annual Meeting of the Medical Society of the State of New York Buffalo New York April 29 1941.

* This paper is, in the last analysis based upon the research and teaching of Hans von Baeyer. Von Baeyer has given us in countless contributions a new and stimulating realization of the role that the musculature plays for man's posture and locomotion. The influence of his teaching on the rational treatment of their disorders cannot be overrated.

The shadow of Nazism fell on the last years of his life. He died in his Fatherland but exiled from the great institution he had created. On January 22, 1941 a coronary occlusion put an end to von Baeyer's work.

compression stresses. As a result, the auxiliary soft tissue structures—namely, the muscles with their tendons and the ligaments—are forced to participate to an abnormal degree in the transmission of compression and tensile stresses. The ligaments offer considerable passive resistance but gradually become overstretched, the faulty static alignment becomes worse. When the ligaments give way, opposing articular surfaces lose their normal relation and become incongruent. Incongruence of articular surfaces interferes with normal function and renders it painful, especially under weight-bearing. Such pain calls for reflex action of the muscles. They try to restore normal alignment to avoid strain on the ligaments and incongruence of the articulations. As a result, these muscle groups are under abnormal strain and become fatigued. Waste products of muscle metabolism accumulate with the sequelae of pain, changes in circulation, and malnutrition.

The flexibility and adaptability of the foot required in the various phases of standing, walking, running, climbing, and jumping entail a considerable degree of skeletal instability below the ankle. The lower leg and foot muscles must guarantee functional stability where the skeletal stability is lacking. This purpose is achieved through the physiologic balance mainly between the lateral group of the peroneal muscles and the medial group of the tibial muscles. Both muscle groups cooperate under normal conditions to maintain the correct static alignment of the foot for optimal support of the body weight in all phases of standing and walking. With the heel in valgus position, weight-bearing causes abnormal strain on the medial structures at the ankle. In order to maintain correct alignment the tibial group must make greater efforts, while the peroneal group is relaxed. If this condition prevails for some time, the equilibrium between the two muscle groups is definitely disturbed. At first, the patient will note fatigue and pain in the tibial muscles, then comes the point where these muscles, overworked and suffering from accumulation of waste products and lack of nourishment, suddenly contract with a last spastic effort, pulling and holding the entire foot in an unphysiologic position of total supination. The onset of this final stage of chronic damage to this muscle group comes suddenly, resembling an accident. One may assume that a minor incident during walking—for instance, an unevenness of the ground—added to the imbalance already present, has furnished the

last straw. We now have the picture of an acute disorder of both posture and locomotion caused by a disturbance of the physiologic balance between pronating and supinating muscles.

If we recognize the characteristic picture of an extremely painful, completely rigid flat foot as the result of a disturbance of the equilibrium of the muscles controlling the position of this foot, the first aim of our treatment must be the restoration of the physiologic balance. Relaxation of the spastic or contracted muscle group is the logical requirement. This can be achieved in many ways. We will select those measures that restore muscular balance and, consequently, painless function of the foot with a minimum expenditure of time and energy. Relaxation would be readily accomplished by general anesthesia, which, however, is indicated only if major surgical procedures are intended.

Quick and complete relaxation of the spastic muscles in a rigid foot is obtained by local anesthesia if properly applied. There are two methods of using local anesthesia for this purpose. One consists of injections of novocain into the ankle joint. By the other, which in my experience is more effective, the affected muscle groups are infiltrated with novocain.⁵ I inject up to a total of 100 cc of a 0.5 per cent solution without epinephrine at three or four points into the spastic muscles. After a period of from ten to twelve minutes, anesthesia becomes effective, the tibial group is relaxed, and the foot can be brought back into normal alignment.

It is also possible to overcome the rigidity of the foot without anesthetics. In selected cases skillful manipulation may restore the muscular equilibrium with immediate relief of pain and spasticity, especially if we have succeeded in distracting the patient's attention. When we state that manipulation alone under favorable circumstances can restore the muscular balance, we must emphasize at the same time that it is not a manipulation of displaced joints or slipped articulations as claimed by osteopaths, what actually happens in a sudden stretching and relaxation of the contracted muscle group which accounts for the sometimes spectacular result.

Between the two extremes of general or local anesthesia on the one side and manipulation on the other, practically all modalities of physical therapy may be used to obtain the desired result. Rest, heat, and histamine iontophoresis are among the most effective. Restoration of physiologic balance between

pronating and supinating muscle groups on the foot cures the acute disorder of the painful, rigid flat foot. It does not, of course, remove the underlying cause of the disorder, and additional therapeutic measures are necessary to correct permanently the faulty static alignment and to eliminate its effect on all the structures that have suffered from the strain of abnormal weight-bearing.

It is not within the scope of this paper to discuss in general differential diagnosis and treatment of pathologic conditions of the foot. I have used the well-known picture of a painful, rigid flat foot merely as a classic example for the significance of muscular balance in acute disorders of posture and locomotion. The course of events, described for the development of the painful, rigid flat foot and its logical treatment, applies to similar conditions in other regions of the body, especially in the back.

I shall now discuss the back in reference to acute disorders of posture and locomotion. Backache of muscular origin is of greater importance than the disorders of the foot. It occurs much more frequently, and entails, as a rule, prolonged disability with all the implications including the significant economic factor. Its great tendency to recur is only too well known. Furthermore, the nature of muscular backache is not readily understood and, as a result, treatment may be inadequate.

A survey of the current literature shows a flood of publications on the subject of low back pain and of the injured back and its treatment.^{1,2} There is no doubt that an acute attack of disabling pain in the back may present one of the most puzzling problems for differential diagnosis. As far as I can see the chief interest in this subject in recent years has been focused on the discussion of two aspects of the manifold problem.

1 On the role of the intervertebral disk and its herniation, which seems to occupy a prime position in the considerations of orthopaedic and neurosurgeons.

2 On the slipping or displacement of the sacroiliac articulation. This hypothesis has found more attention on the part of the physical therapists under the noticeable influence of osteopaths who claim to cure the acute painful back by manipulation of slipped articulations. The possibility of the purely muscular origin of an acute disorder of the back has attracted little attention. This is showed by the fact that the term "acute lumbago" is rarely used nowadays, while a

diagnosis of sacroiliac syndrome, sacroiliac dislocation, lumbosacral arthritis, sciatica, etc., is favored.

To prevent misunderstanding I should like to emphasize that an acute attack of low back pain may be caused by a great variety of pathologic conditions, in many instances, differential diagnosis is difficult and requires the aid of medical, surgical, urologic, gynecologic, and neurologic examinations. It has been my experience, however, that the incidence of purely muscular disorders causing acute back pain is much higher than is generally recognized, and this statement is borne out by the result of the treatment. It is therefore worthwhile to study the back conditions under discussion from the same point of view as we have done in the first part of this paper for the rigid flat foot.

The typical picture of an acute attack of lumbago is well known. A man sitting at his desk in a swivel chair, reading a newspaper, bends over to the right to pick a section of the paper from the floor. He experiences a sudden sharp pain in the right lumbar region and is unable to resume the erect posture. With difficulty he gets up from his chair, supporting himself with his arms, his trunk is shifted and bent toward the right side, and an attempt to straighten up fails. Pain may or may not radiate down to the right leg. Every movement is painful, even coughing or sneezing causes a pain in the right lumbar region. Examination shows that the trunk is shifted toward the right side over the pelvis, the lumbar lordosis is flattened out or reversed into kyphosis. The right lumbar erector spinae muscle group is conspicuously prominent and markedly rigid. A straight leg raising test shows a positive Lasegue on the right side, it may also show a hamstring spasm on the left side with pain referred to the right lumbosacral region. The patient may localize his pain over the right sacroiliac joint and not in the region of the spastic lumbar muscles.

Regardless of the origin of the pathologic condition, this patient presents the picture of an acute disturbance of the physiologic balance between the right and the left lumbar erector spinae muscle groups. In this case we have a unilateral disturbance. In other instances the lesion may be bilateral or symmetric. A bilateral attack of acute lumbago occurs for instance when a person standing at the washbasin bends forward while brushing his teeth. When attempting to resume the erect posture he feels a sudden sharp pain in the back, as if struck by lightning, and he is

unable to straighten up Examination shows lumbar kyphosis, marked spasticity of the bilateral erector spinae muscles and, frequently, a boardlike rigidity of the abdominal muscles The disturbance of the physiologic balance between muscle groups acting on the spine concerns the erector spinae muscles posteriorly and the iliopsoas and abdominal muscles anteriorly⁷

We are now concerned with a painful and disabling disorder of posture and locomotion of the spine due to an acute disturbance of the physiologic balance between bilateral synergists (in the case of the unilateral lesion) or between agonists and antagonists (as in the bilateral lesion) The picture is similar to the one presented by the acute spastic flat foot Restoration of the physiologic equilibrium between the affected muscle groups is the first and logical aim of our treatment This requires the application of measures that will effect a complete relaxation of the spastic or rigid muscle group Before discussing the modalities of treatment which have proved most useful for this purpose, I should like to discuss the nature of the muscular disorder

Man's erect posture and the multitude of static and dynamic functions of the spinal column depend to a large extent upon the function of the muscle groups that act on the spine and control the postural relation of the spinal column and the trunk to the "closed chain" of the pelvis and the lower extremities A weakness of the lumbosacral region is, generally speaking, the price we still have to pay for the privilege of the erect posture Man's adaptation to the erect posture is not yet complete as is showed by the many skeletal variations that occur in this region The greater the individual instability at the lumbosacral junction, the greater are the demands made upon the musculature Analogous to what we have seen at the ankle, here, too, skeletal instability requires muscular stabilization. Although nature has endowed the human body with an admirable system of reserves and safety devices in order to maintain the physiologic functions even under adverse circumstances, it is readily understood that the imperfection of human nature accounts for frequent disorders The lumbar musculature bearing the greater part of the burden imposed by the erect posture is prone to fail under undue strain, especially in certain types of individuals Muscles are under abnormal strain whenever there is a discrepancy between their functional capacity and the demands made upon them. If the muscles

are normal, their physiologic balance will be disturbed by abnormal demands These may be due to intrinsic and extrinsic causes The latter are (1) overexertion from heavy physical labor or athletics, leading to muscular fatigue, and (2) trauma, causing tear of muscle fibers and hematoma

Among the intrinsic causes defective posture plays the predominant role because it entails habitually strained muscles and a lack of balance of the bones at the joints Von Baeyer¹ has pointed out that posture is the status present at the beginning and at the end of motion The essence of posture is physiologic balance or equilibrium If there is no equilibrium, there is motion Physiologic posture requires a minimum of muscular effort Active contraction of muscles means increased metabolism, physiologic muscle tone does not Defective posture necessitates constant muscle action, leading to muscular fatigue and an accumulation of waste products Next to defective posture we have to mention pathologic conditions of the skeleton which may increase the demands made upon the musculature This will be the case in symmetric and asymmetric deformities—e.g., a gibbus of the dorsal spine or a fixed scoliosis disturbing the physiologic balance between the bilateral synergists acting on the spine—and in spondylarthritis or spondylosis where the muscles are called upon to immobilize the diseased parts of the skeleton to avoid pain Finally, we must list pathologic conditions of the viscera and the central nervous system which lead to "muscular defense" to prevent pain The common denominator of all the conditions mentioned is that they place an undue strain on normal muscles, leading to an unphysiologic condition of these muscles and preparing for the occurrence of an acute attack of lumbago

On the other hand, we must consider pathologic conditions of the musculature proper which make it unfit even for physiologic demands made upon it Such conditions are general weakness of the musculature, constitutional or conditional, and diseases of the muscle fibers or the interstitial tissues, e.g., myositis or myositis ossificans Exposure to cold and humidity undoubtedly has a detrimental influence on the physiologic function of the muscles We must consider among this group, also, the results of many of the intrinsic and extrinsic causes mentioned above which lead to undue strain and which eventually impair the physiologic function of the affected muscle groups.

At this point I should like to discuss the so-called "myogeloses."

The term myogelosis^{*} was introduced by Fritz Lange and Heinrich Schade in 1921, describing a pathologic condition of the musculature characterized by painful hard nodules in the muscle fibers. These two authors, working independently, believe that myogeloses present a distinct pathologic entity and that the palpable changes of the muscle fibers are organic in nature. They have not been able to prove the exact nature of these pathologic changes. Histologic examination of excised nodules was negative. The chief objective criteria for the existence of myogeloses were a determination of the circumscribed induration in the muscle with the aid of the sclerometer. Myogeloses do not disappear in deep general anesthesia, and they remain palpable postmortem for approximately ten hours until rigor mortis has occurred (Schade). From these observations both authors concluded that myogeloses are not circumscribed spasms of muscle fibers but organic changes, very likely colloid-chemical in nature. A detailed discussion of the myogelosis problem will be the subject of a later presentation.* It may suffice to state that myogeloses are frequently found in the pathologic conditions of the musculature presented today. As a rule, they respond well to treatment—not only to the deep massage or gelotripsy recommended by Lange and Schade but also to histamine and other modalities of physical therapy.

An acute attack of lumbago occurs most frequently when a sudden uncontrolled motion puts an additional strain on a muscle group that already has been taxed to capacity for one or several of the reasons mentioned. A slight disturbance of the physiologic equilibrium, insufficient to interfere with the function of normal muscles, furnishes the last straw, the strained muscle group contracts with a last spastic effort, and the muscular balance of either bilateral synergists or of agonists and antagonists is finally deranged. This necessarily leads to a shift in the relations of the pertinent sections of the skeleton, hence, the common assumption that a displacement or slipping of one or several joints has occurred. Because pain in an acute attack of lumbago is frequently referred to the sacroiliac rather than to the lumbosacral region or the lumbar muscles, osteopaths and their

followers have established the routine diagnosis of a sacroiliac sprain or dislocation. There is not time to discuss the anatomy and physiology of the sacroiliac articulations and to explain why it is my firm conviction that a displacement of the sacroiliac articulation is highly improbable, if not impossible (with rare exceptions in the case of severest trauma). It may suffice to state that the manipulative procedure carried out by osteopaths and by some orthopaedic surgeons frequently is successful because it restores the muscular balance of the erector spinae muscles. We fully agree with regard to the classic symptoms of an acute attack of lumbago and with the possibility of immediate relief of the patient's suffering and a restoration of the physiologic balance of the affected muscle groups through adequate manipulative procedures. We do not agree with regard to the conception of the underlying pathologic condition and the name with which it is labelled.

The rationale of the treatment of the acute disorder of posture and locomotion caused by an acute attack of lumbago is essentially the same as outlined for the spastic flat foot. Complete relaxation of the spastic muscle group is a prerequisite for restoration of muscular balance. Among the various therapeutic modalities that could serve this purpose, I should like to mention two that in my experience have proved to be most efficient, while at the same time their application is simple and safe.

Since its introduction by Deutsch,² of Budapest, in 1931, I have made the most extensive use of histamine iontokataphoresis in the treatment of many pathologic conditions of the musculature, especially those characterized by muscular rigidity and myogeloses. Histamine treatment alone or in combination with other modalities of physical therapy is the treatment of choice for a majority of cases of acute lumbago. I use a histamine solution 1:10,000 and a galvanic current of 6 milliamperes for six minutes per field of application. Histamine is applied not only to the spastic lumbar muscles but to the entire back and the gluteal muscles and, occasionally, to the posterior aspect of the thigh. In some instances the first treatment brings a dramatic relief, in more severe cases treatment must be repeated on the following days. As a rule, three treatments suffice to restore the muscular balance of the erector spinae muscles and to enable the patient to resume his occupation.

Injectations of novocain into the muscles as

*"Myogeloses. The Significance of Pathologic Conditions of the Musculature in Acute Disorders of Posture and Locomotion," read before the American Congress of Physical Therapy, Washington, D. C. September 4, 1941.

recommended for the treatment of the spastic muscles in the rigid flat foot have not been so effective when applied to the lumbar muscles. I have discarded the use of novocain injections in favor of the histamine treatment. During the past two years, however, I have availed myself of a new type of injection which was recommended by Tarsy¹⁰ for the conservative treatment of low back pain.

Two cubic centimeters of "eucupin" in oily solution, a bactericidal local anesthetic of low toxicity and prolonged analgesic action containing 2 per cent iodine, are injected deep into the lumbar erector spinae muscles with a $1\frac{1}{2}$ -inch, 22-gage needle. The needle is inserted vertically to its hilt at a point slightly proximal to the tip of the transverse process of the fifth lumbar vertebra. If no blood is aspirated, $1\frac{1}{2}$ cc are deposited. During the injection of the last third of the solution the needle is gradually withdrawn. The lumbar region is then subjected to a vigorous massage. A few minutes after the injection prompt relief of the muscular rigidity is noted and the muscular balance may be restored. This type of treatment is especially suitable in cases of unilateral lumbago, where pain is localized in the lumbar erector spinae muscles rather than referred to the sacroiliac region. The injection may, of course, be supplemented by the various modalities of physical therapy and it may be repeated after two or three days.

Histamine iontokataphoresis and eucupin injections thus represent, in my experience, the preferred treatment for the acute attack of lumbago. It is, of course, not sufficient to treat the acute symptoms only. Most of these patients require not only a complete and careful examination in order to determine the underlying pathologic changes responsible for the acute disorder. They also require prolonged aftercare after the acute symptoms have disappeared and prophylactic measures to prevent a recurrence, which is so common in the conditions characterized by a disturbance of the physiologic muscular balance. The discussion of this phase of the treatment is beyond the scope of this paper.

A word may be added with regard to injections into the sacroiliac region. In selected cases where the lower back pain is connected with a radiation of sciatic distribution, injections of a 2 per cent filtered solution of iodine in alcohol into the sacroiliac region of the affected side has given good results. The injection is carried out with a 1-cc tuberculin syringe and a 3-inch, 22-gage needle. The

technic is not easy. With the patient in the prone position the needle is inserted $\frac{1}{2}$ to 1 inch lateral to the median line at the level of the proximal margin of the sacroiliac articulation. The needle is introduced in a direction toward the anterior superior spine of the same side. When the needle penetrates through the strong and tough ligamentous structures on the posterior aspect of the sacroiliac articulation, a definite resistance is felt. After this is overcome the needle comes in contact with bone, it is slightly withdrawn and from 0.2 to 0.4 cc of the solution are deposited. At this moment the patient experiences a sharp pain that frequently radiates down to the knee. The needle is then withdrawn, and the patient is allowed to get up after a short period of rest in a recumbent position.

This type of sacroiliac injection has a definite place in our armamentarium, provided the suitable cases are properly selected and the technic is correct. I have learned this method, which apparently has not been published, from Walter I. Galland and have used it for more than six years with good success. It is not quite easy to give a satisfactory explanation for its action. I believe that the small amount of iodine deposited in the midst of the network of nerves in the sacroiliac region causes a marked and prolonged reflex hyperemia throughout the entire distribution of these nerves.

Summary

A considerable number of acute disorders of posture and locomotion are of purely muscular origin. They are characterized by a disturbance of the physiologic equilibrium between muscle groups that function as agonists and antagonists or as bilateral synergists.

The spastic or rigid flat foot and an attack of acute lumbago serve as typical examples for the significance of muscular balance in acute disorders of posture and locomotion. The recognition of the purely muscular nature of such disorders shows the way to efficient treatment. Histamine iontokataphoresis and injections of eucupin into the spastic lumbar muscle group are recommended for the treatment of the acute disorders of the back. Iodine-alcohol injections into the sacroiliac region are of considerable value in selected cases with sciatic distribution of pain. Novocain injections into the spastic tibialis muscles lead to the restoration of muscular balance in the rigid flat foot.

THE CHOICE OF A BOY OR GIRL

"The newspapers and popular magazines have heralded the announcement that science can fix the sex of babies. One must view this from different standpoints. Will the possibility which is implied add to the world's troubles or, by making certainty out of uncertainty, contribute anything to happiness? Prospective and potential parents naturally have an interest in the claim that the sex of their young hopeful can be made to order and that they may have a girl baby or a boy baby according to individual preference or desire," writes Dr. George W. Kosmak in *Maternity Center Briefs*.

"The glowing accounts of what has been accomplished by experiments in the laboratory with rabbits and rats does not mean that such results are readily transferred to human beings or that isolated instances of a boy or girl baby, according to desire, prove the truth of the theory that the choice may easily be achieved by acid or alkaline diets. And if you could control the matter in such a simple fashion, would it in the end be wise? The beautiful uncertainty whether the coming baby is a boy or a girl has its advantages. Father may have his heart set on a boy and mother may prefer a girl. But mother, according to the new pronouncement, can control the situation by drinking an abundance of bicarbonate of soda or of lactic acid "cocktails," according to directions. Her personal wishes would be fulfilled, father to the contrary notwithstanding.

"No, it were better to let Nature decide. She seems to have maintained a satisfactory proportion in the past between the two sexes, and we had better continue to let her have her way. People must remember that in such matters individual preference counts for little in the

natural scheme of things. And, I repeat, would there be any real gain if we had our way in such matters? Nobody in authority has dared to say so for the simple reason that conscientiously they can't. It were better if all of these speculative theories were set aside and more attention given to the production of healthy babies, be they boys or girls.

"Either John or Jennie should be welcome. As the final outcome is surrounded with so many uncertainties, the failure of mother to bring forth the expected kind of baby will lead to incrimination and disappointment, and of what use is it all? Any normal, healthy baby should be welcomed, whether it be boy or girl. The world needs both."

"Old Dame Nature's not going to put anything over on us this time!"

AIN'T IT AWFUL?

From the Dallas (Texas) News

Docile Germs Provide Thief Perpetual Alibi

Because he is a recognized typhoid carrier, a 16-year-old Negro boy has become the problem child of Dallas County juvenile authorities. He can steal with impunity, since no jail or reformatory will accept him because of the danger of a typhoid epidemic.

The youth, who has been three times released from Gatesville reformatory because he endangered other inmates, was arrested again

Saturday for stealing a bicycle. He told R. R. Harvill, bicycle theft officer, where the stolen bike could be found, readily admitting prowling several cars recently as well as the theft of an additional bicycle.

He admitted freely, Harvill said, because he knows that at present he cannot be punished. He was released as usual after questioning—

THE VARIOUS FORMS OF SHOCK THERAPY IN MENTAL DISORDERS AND THEIR PRACTICAL IMPORTANCE

LOTHAR B. KALINOWSKY, M.D., New York City and Brentwood, New York

THE main interest in today's psychiatry centers around problems of treatment. This in itself is a fact of far-reaching significance in a field so little therapeutic-minded until a short time ago.

In the beginning the various shock treatments were overestimated by some psychiatrists, belittled by others. Today they are sufficiently recognized to discuss them before a general medical society. Sensational newspaper reports keep the interest of the laity awake. The general practitioner is constantly asked about them, and one cannot overstress the importance of his role in a field where early diagnosis and recommendation of early treatment are decisive. Therefore, we shall try to give here an account of what shock treatments are and how much of them is beyond the stage of research.

It is more than difficult to discuss in a brief paper facts and problems in this field that is so much in a state of flux. The ideas here presented are based on a year's trip through most of the European centers of psychiatric shock therapy, followed by work in shock therapy in New York State. This made it possible to utilize in this paper experiences of various psychiatric schools.

The term "shock treatment" is misleading because it is applied in general medicine to something quite different. It was introduced in psychiatry by Sakel¹ for his insulin treatment by means of which the patient is brought into a hypoglycemic coma. Later on it was likewise used for the different methods to produce epileptiform attacks as a treatment for mental disorders—namely, metrazol treatment and electric shock treatment.

These three methods are the main types of shock therapy nowadays. But it is usually overlooked that they had an important predecessor in Klaesi's² "prolonged sleep" treatment, described in 1922 and still done as a routine treatment, besides the others in the leading institutions in Switzerland. The patient is brought into a continuous sleep for eight to twelve days. It was considered

dangerous as long as somnifen was used, it is now done with a mixture of barbiturates, chloralhydrate, and paraldehyde, induced by enema. Its advantages have mostly been seen in the quieting effect and in bringing the patient into a good psychotherapeutic relation to the doctor. The best results are seen in persons affected with catatonia and in the various stages of the manic-depressive group.

Another forgotten predecessor, already called "shock treatment," is Schuster's³ treatment with anaphylactic shocks (milk injections repeated at ten-day intervals).

A wider application was given to insulin treatment than any other method since 1934. Hypoglycemia had been tried as a symptomatic treatment in morphine addicts and in psychoses. But what Sakel's predecessors avoided and feared, i.e., the production of full coma, became the main point of his technique. It is due to this treatment and to the elaboration of a precise technique that a systematic treatment of schizophrenia was initiated in all psychiatric places in the world. We can state today that whatever way psychiatric therapy may take in the future it was the insulin treatment that made psychiatrists therapeutic-minded. It was shown that physical treatments are helpful in dementia praecox and manic-depressive psychosis and that they are superior in efficiency to psychotherapeutics as far as the major psychoses are concerned.

We cannot give here details about the technique, but I can state from what I have seen in most countries that almost everywhere the original technique is being used, at least in its essential features. Only few authors recommend subcomatous doses and claim results with this so-called ambulatory insulin treatment (Polatin). Treatments should be given five or six days a week and thus for two, three, or more months.

Contraindications are acute forms of tuberculosis, liver and kidney diseases, myocardial damage, and coronary disease.

It is the definite opinion of most workers that it is desirable to bring the patient into as deep a coma as compatible with safety. Many feel that in otherwise hopeless cases it is even worthwhile to take a risk and to leave

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

From the Department of Psychiatry of the New York State Psychiatric Institute and Hospital.

the patient in a longer coma. All reports about cases complicated by a protracted coma show clearly that those cases, when they were brought out from their prolonged comatose condition, had an extremely good recovery rate (Binzley, Anderson, *et al* ⁴). A special technic to obtain a prolonged coma at will is given by Kraulis ⁵.

As far as complications are concerned, we can say that fatal accidents are rare. In all places with a good technic and a sufficiently numerous and well-trained medical and nursing staff, the death rate is kept below 1 per cent. The most important complication is the above-mentioned "prolonged" coma. When this was first seen, large doses of glucose were given to overcome it, but it is known today that it is not a prolonged hypoglycemic coma but apparently an expression of acute brain cell disease.

A second group of complications are those on the part of the cardiovascular system. They are rare but dangerous. They may occur not only during deep coma but also in the precomatous state. However, the possibility of such events is no good argument against insulin or other shock treatments. It should not be forgotten that in dementia praecox we are dealing with a progressive disease that kills the personality of the patient and, therefore, in many respects, is a more terrible disease than many organic diseases with rapid fatal results.

Epileptic seizures are a frequent occurrence in insulin treatment but are not absolutely to be considered as complications. They may occur during the coma as well as in the precomatous state. A patient of Katzenelbogen⁶ had eleven seizures the same day, the following day she showed a full remission. These and similar experiences led to the idea that epileptic seizures in insulin treatment might be of therapeutic value. Whether the cases with spontaneous convulsions during the hypoglycemic state really have a better recovery rate than others is still being discussed. This opinion, however, and the apparently incorrect idea that epilepsy and schizophrenia do not occur in the same person gave the theoretic basis for the second important group of shock therapy, the so-called convulsive treatments (von Meduna⁷). This group has in common the provocation of epileptic seizures. They are produced either pharmacologically with metrazol and similar drugs that are toxins for the brain cells or with electric stimulation of the brain—the so-called electroshock treatment.

The technic of metrazol treatment will not be discussed in detail, it consists of a quick intravenous injection of 5 cc or more of a 10 per cent solution of metrazol. The fit is preceded by a latent period during which the patient experiences a rather disagreeable sensation of anxiety. The treatment is generally given two or three times a week. A treatment course consists of fifteen or twenty applications, but improvements are usually achieved between the fourth and the eighth treatment. The short duration of this and other convulsive therapies makes it possible that a far greater number of patients can be benefited by convulsive treatment than by hypoglycemic treatment. Insulin and convulsive treatments are often used simultaneously, because in this way the therapeutic effect is considered to be more intense. They can be combined in different ways. Either the course of insulin treatment is interrupted by days on which convulsions are given or the metrazol is given at the beginning or during the insulin coma.

The opinion about metrazol treatment varies greatly in different places. In most European countries it has its place equal to insulin treatment. In England I got the definite impression that it finds a considerably greater application than insulin. Metrazol therapy has found its strongest opponents in New York State. Several health authorities even objected to its being used. It is all the more important that, recently, an objector to the method, Cheney, and his coworkers⁸ reported favorable results and strongly suggested resumption of its use where it had been discontinued.

Some unfavorable statistics about the results not so much brought up the sharp fight against the metrazol method as overvaluation of certain ill-effects.

Of these, one group has to be discussed here—namely, the fractures and dislocations, especially the vertebral fractures. After the method had been used for years, the explanation for frequent, usually slight backache was found in vertebral compression fractures. These x-ray findings were generally confirmed, but it must be stated that they have a limited or no clinical significance at all. Polatin and coworkers,⁹ who gave the first report, warned against exaggerated conclusions. The psychologic factor of the "broken back," however, considerably discredited a method that is of definite help in psychiatric treatment.

Today we have found many ways to pre-

vent these complications almost completely. Fractures of the long bones and dislocations can be avoided by a careful technic. The same holds good for the vertebral fractures, as Cheney's report shows. Chemical means, like curara and erythroidin, are used in order to paralyze the muscles and prevent the strength of their contraction, which is the cause of those fractures. The same, however, can be achieved by good position of the patient. Since these fractures occur in the anterior part of the dorsal vertebrae, we bring the patient into an exaggerated hyperextension of the vertebral column and, thus, are able to avoid fractures without the use of curara, which gives the patient acute discomfort and sometimes makes breathing more difficult.

It could, furthermore, be shown that these radiologic fractures have no clinical importance whatsoever, re-examination of those patients, which has been made two or more years after such fractures, showed that no late effects are produced which eventually may hamper the working capacity of the patient.

Other more serious complications are extremely rare. The greatest disadvantages remain as sensation of fear before, frequent intravenous injections, and a rather unpleasant condition when the injection does not bring about a convulsion.

These disadvantages, in 1937, led Cerletti and Bini¹⁰ to the attempt to produce convulsions by means of electric current. This electric shock treatment, recently introduced in many places in this country, uses the ordinary house current. We send 60 to 120 volts through large electrodes applied to both fronto-temporal regions for the duration of usually not more than $\frac{1}{10}$ second. We know that only a small part of this current, probably less than $\frac{1}{100}$, reaches the brain, and no damage from the current has to be expected. No serious accidents of any kind have been observed in those institutions using this treatment (Kalinowsky and Barrera¹¹).

Electric shock therapy gives two responses that are analogous to the corresponding phenomena in epileptic patients. With subconvulsive doses, we obtain petit mal consisting of unconsciousness, with apnea from 1 to 60 seconds. Increasing the voltage, we obtain typical grand mal convulsions. Either response can be produced at will. In old persons and in those patients where the full strength of a convulsion is undesirable, petit mal can be given, though we could show that

the therapeutic effect is definitely not the same as with grand mal seizures.

Electric shock therapy is given at the same intervals as metrazol. Its great advantages are simplicity, minimal expense, and a complete lack of discomfort on the part of the patient, who has a perfect amnesia for the treatment itself and retrograde amnesia for all the preparations. Therefore, perfect cooperation of the patient is another advantage.

Before I discuss the indications and results of the various treatments, I wish to mention briefly three other methods still in the trial stage. Many investigators believe that the common factor in all the mentioned treatments is depression of brain metabolism. With insulin this is caused by the lack of sugar, with metrazol, by the lack of oxygen. In the so-called nitrogen or "anoxic shock" treatment (Himwich, Alexander, and Lippetz¹²) anoxemia is achieved by administration of nitrogen or other gaseous mixtures, this being done preferably by an experienced anesthetist. Some reports are favorable, but information that I was able to obtain from other places where this method has been tried was not convincing.

Apparently not much applied so far is the "faradic" shock treatment of Berkwitz.¹³ Here, a current, too low to produce even unconsciousness, is supplied. Shortly after this faradization, unconsciousness is obtained by intravenous injection of a barbiturate. It is our impression that eventual results are obtained not by means of electric current but by the following artificially produced sleep.

The most recent method, still in the experimental stage, is the low-temperature treatment as used primarily for cancer, known to the public as "frozen sleep" treatment and going to be published as hypothermia by Talbot and Tillotson.

The crucial point of treatments lies in their results. The answer should be expected from the percentage of recoveries and improvements. But no good comparison is possible because opinions about the frequency of spontaneous remissions in the preshock era vary considerably. Before I mention some of the data available, I want to state that the statistical approach is not the only one. After speaking with psychiatrists of various schools and countries, I found that they all feel that the different shock treatments bring about definite results, which are not overwhelming but represent a distinct progress. Insulin, as well as the two convulsive treatments, was recommended originally for de-

mentia praecox. Later on, it was found by American authors that the convulsive therapies have their main indication in the manic-depressive group and in involutional psychoses where the most spectacular results are obtained. Everyone who has seen depressive patients mute, stuporous, and tube-fed for years, who after three or four convulsive treatments recover completely, will no more belittle the importance of these treatments. In this group, amazing recoveries are achieved in the majority of all treated cases.

Results in schizophrenia are less striking, but they occur in a number sufficient to satisfy everybody who is seriously working in shock therapy.

As to statistics, we find big differences. The percentage of improvements is higher in European statistics. But when we consider the ratio between treatment remissions and spontaneous remissions, we come to the strange result that the New York State statistics by Ross and Malzberg¹⁴ for schizophrenia are more favorable. They find nearly three times as many recoveries in insulin-treated as in nontreated patients, whereas the largest Swiss and German statistics only come to a ratio of less than 2:1 between treated and untreated cases. In the group of much improved cases this difference is still greater.

The explanation is that in American statistics the figures for recovery without treatment are extremely low (3.5 per cent). Reports utilizing figures from various European countries come to 20 per cent spontaneous remissions. This considerable difference is sometimes explained by supposing that the diagnosis "schizophrenia" is made more frequently in Europe than in the United States. Psychiatrists who have worked on both continents cannot accept this explanation. Since statistics are generally based upon cases paroled or discharged from the hospital, it is more likely that a difference in parole policy is the explanation. Apparently, a parole decision is less easily made in this country.

A fact of greatest importance resulting from all statistics is that persons with schizophrenia with short duration of disease have a better outcome than long-standing cases. In cases of less than six months' duration, between 55 and 80 per cent remissions are reported after insulin therapy by reliable workers. Cases of between six and twelve months' duration showed about 25 per cent less remissions. The rate of full remissions decreases constantly with the longer duration of the disease. Furthermore, relapses are

rarer in patients treated during the first year of the disease and become more frequent the later patients are subjected to treatment. This fact has to be stressed again and again because it shows the great danger of reluctance on the part of the practitioner and of many psychiatrists in referring patients for treatment. It is a mistake made in many places to let valuable time slip by hoping that spontaneous recovery might still occur.

Statistics of metrazol treatment in schizophrenia are still more contradictory than with insulin. Ross and Malzberg's report shows even fewer recoveries than in untreated schizophrenia. Most of the other statistics, including Cheney's last report, are far more favorable, and many statistics go up to such figures as seen in insulin treatment. In electric shock treatment the time of observation is still too short, but our own experience in two parallel series, one treated at the New York State Psychiatric Institute and the other at Pilgrim State Hospital, compares favorably with experiences with other methods.

It would be of great help if we knew more about the treatment prognosis. Prognostic aids are given by transient improvement after intravenous injection of sodium amytal (Harris, Horwitz, and Milch¹⁵), certain Rorschach findings (Piotrowski¹⁶), and other psychologic performance tests. But more important for the choice of patients and prediction of the therapeutic outcome are clinical experiences. We have mentioned the importance of the duration of the disease. Other favorable factors are conservation of a certain affective responsiveness and, in older cases, a history of previous remissions which makes even old cases worthwhile for treatment. An unfavorable factor is seen in the admixture of psychoneurotic symptoms. This latter point is in accordance with my own experience—that cases of pure psychoneuroses get the least benefit from all kinds of shock treatments.

The various groups or types of schizophrenia are believed to react differently to treatment. It is said that acute paranoid types and agitated catatonic types react better to insulin, stuporous catatonic types and hebephrenic types react more to convulsive therapy. Opinions in this respect vary widely. Apparently the treatment prognosis goes parallel to the prognosis for spontaneous remissions in the various types.

In affective disorders pure convulsive treatment has become more and more the method of choice. Bennet¹⁷ in this country was

the first to draw attention to the excellent response of depressions of the manic-depressive group, as well as of involutional cases, to metrazol treatment. Figures of 80 per cent and more were given. Cheney's recent metrazol report comes to similar results. Our own electric shock experience gives the same favorable picture for depressives as well as for manics.¹⁸

The practical value of the various forms of shock treatment cannot be doubted. What is the best possible way to utilize the new methods? It has to be admitted that we have no idea how these treatments act and that "we treat an unknown disease by unknown means" (Frostig). These methods break up a psychosis, and rapport with the world is re-established. We do not know how this occurs, but we see empirically that we obtain results. The only practical conclusion, therefore, can be that we have to treat our patients with one or another of these methods. A certain reluctance is felt in many places—a fact that one gathers not from literature but from personal contact with people. Disappointments give no right to give up. The most consistent argument one hears is the occurrence of relapses, if this were an argument against treatment, no cancer therapy would exist. Our chances are certainly better than in cancer, because relapsed psychotic patients offer a good prognosis on retreatment. We should not forget that every day outside a mental institution is a gain of life for the individual and his family and a financial gain for the community.

Treatment of large groups of patients will increase our experiences. At this time and for several years to come it will be a moot question to ask whether insulin or metrazol or electric shock is the best treatment. The best results will be achieved by a combination of the different methods in different ways. The various methods are not meant to compete but to complete each other.

This leads to the suggestion that special treatment units should be developed in all state hospitals as it was recently done in this state at Pilgrim State Hospital. In these treatment units, all methods should be used, combining them in a purely empirical way. Relatively large numbers of patients can be treated today, thanks to the convulsive therapies, which are simple and act quickly if they act at all. Thus, the more intense insulin treatment can be reserved for selected cases, perhaps after an attempt with the other methods. Insulin and the convulsive methods

are beyond the experimental stage, and further progress in therapeutic knowledge should come from studies on large groups of patients in state hospitals.

We should be able to treat all new patients who come to a mental hospital before they become chronic and institutionalized. It is another weak argument against shock therapy that it is not effective in old standing cases. All cases have at one time been recent. The population of state hospitals will decrease considerably when all new admissions can get the chance of some sort of shock therapy. I have tried to deal with all the various shock treatments in this short paper because in my opinion only common consideration of all the methods can bring us forward. These new treatments give the patient a chance to recover, they give the community the possibility of decreasing the number of inmates, to clinical research they show new possibilities for psychiatric understanding, and to the individual psychiatrist they give a satisfaction that he has missed so long—to become an active therapist in, so far, untreatable diseases and, thus, to be a physician in the sense of the word.

Discussion

Dr. Ralph W. Bohn, *Helmuth, New York*—It is a pleasure and an honor to discuss so able an exposition of the various types of shock therapy. Dr. Kalinowsky's paper is concise but inclusive.

There was only one point to which I take exception and that is the last sentence. As a psychiatrist I have felt just as competent a physician as those who deal exclusively in drugs or surgery. I believe that our therapeutic results in recent years more than justify such an attitude.

The introduction of the shock therapies is just another addition to our steadily increasing armamentarium. Dr. Kalnowsky has not exaggerated its importance.

In our enthusiasm for a method that is giving such startling results I feel that we must be careful not to stress the pharmacologic side to the exclusion of the psychic. It is still my studied belief that the shock therapies operate as a threat to the existence of the individual which cannot be ignored and thus force contact with reality. Those cases in which psychotherapy is ignored or neglected are apt to relapse quickly.

At the Gowanda State Homeopathic Hospital we have had continuous experience with Sakel's hypoglycemic shock since he introduced it to the New York State hospitals through arrangements made by our former commissioner, Dr.

Parsons. It was finally necessary to relinquish it reluctantly because of the excessive personnel necessary for safe administration. We have substituted the so-called ambulatory type of insulin therapy with rather encouraging results.

We were among the first to use metrazol and continue to at the present time. Our experiences here coincide closely with those cited by Dr. Kalnowsky. I have been particularly impressed with results in the agitated depressions and the involution melancholias. At the present time I am engaged in accumulating statistics on these two types of cases admitted to our hospital over a period of more than three years. Contrasting the metrazol treated cases with the "untreated," I find that the period of hospitalization has been neatly halved in the former, and the recoveries bid fair to rise appreciably. I hope to be able to make a formal report reasonably soon.

Last, but by no means least, it would seem that sufficient evidence has accumulated to recognize the shock therapies as "accepted treatment."

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The written examination and review of case histories (Part I) for Group B candidates will be held in the various cities of the United States and Canada, on Saturday, January 3, 1942, at 2:00 P.M. Formal notice of the place of examination will be sent each candidate several weeks in advance of the examination date. No candidate will be admitted to the examination whose examination fee has not been paid at the Secretary's Office. Candidates who successfully complete the Part I examination will proceed automatically to the Part II examination held in June, 1942.

Candidates for re-examination in Part I (written paper and submission of case histories) must request such re-examination by writing the Secretary's Office not later than November 15, 1941. Candidates who are required to take re-examinations must do so before the expiration of three years from the date of their original examination.

The general oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted by the entire Board, meeting at Atlantic City, New Jersey, in June, 1942, immediately prior to the annual meeting of the American Medical Association, to be held in the same city.

Application for admission to Group A, Part II, examinations must be on file in the Secretary's Office not later than March 1, 1942.

As previously announced in the Board booklet, this fiscal year (1941-1942) of the Board marks the close of the two groups of classification of applicants for examination. Thereafter, the Board will have only one classification of candidates, and all will be required to take the Part I examinations.

For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

ODE TO AN ULCER

Sent by A. W. H., Calif., who says it was written by a patient who had one

O duodenum miserable
Why is it when I eat considerable
A sense of comfort permeates
My being and full peace creates
But in mid-morn when belly's flat
There comes the weakness of a cat
Must I rush forth to milk a cow
To stem the pangs and stop the row

That started when the hydrochloric
Got frisky with my damned pyloric
Must I forever decorate
My innards at ten, four, and eight
With powders made of God knows what
Is that my fate, is that my lot?

BURNS? (sometimes)
—J. A. M. A.

THE GENERAL PRACTITIONER'S PART IN THE CAMPAIGN FOR THE PREVENTION OF BLINDNESS FROM GLAUCOMA

MARK J. SCHOENBERG, M D, New York City

THE decision as to whether in the future we shall have a small or large number of persons blind from glaucoma rests largely upon the general practitioner

Surveying the facts, we find

1 Out of hundreds of thousands of ambulatory patients daily consulting medical practitioners throughout this land, at least 30 per cent are 40 years of age or more

2 It is within this age group of patients, which constitutes a large part of the clientele of general practitioners and clinics, that one has to look for the present and future glaucoma victims

3 Patients afflicted with glaucoma are potentially—nay, frequently—victims of partial or total loss of sight

4 It is estimated that there are approximately 200,000 blind persons in this country, of whom over 20,000 are blind from glaucoma. In a paper recently published, Pfeiffer and Booth¹ report that of 2,685 cases of blindness 12 per cent were thus affected by glaucoma. In addition, there may be five to ten times as many one-eyed blind and two-eyed partially blind people—altogether 100,000 to 200,000 victims of glaucoma *

5 Blindness from glaucoma is preventable in a large percentage of cases

6 *The general practitioner is one of the first to have an opportunity of detecting or at least suspecting the presence of glaucoma at an early stage* By including a few more items in his list of diagnostic procedures and by asking a few relevant questions he would be able to survey the condition of the visual organs of his patients and discover, or *at least suspect*, the disease responsible for so much blindness

Recently, the National Society for the Prevention of Blindness initiated a campaign to reduce the percentage of blindness due to glaucoma. This organization, in agreement with the ophthalmologic profession, reasons as follows

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941

Chairman, Committee on Glaucoma, National Society for the Prevention of Blindness, 1790 Broadway, New York City

* The probable loss of income due to unemployment caused by blindness from glaucoma would amount approximately to \$10,000,000 per year for 20,000 persons blind from this cause. These figures do not cover the financial loss due to partial disability, etc.

A Early treatment of glaucoma gives good results and saves sight in a large percentage of cases, late treatment does not

B Early treatment cannot be administered without an early diagnosis.

C The medical practitioner's cooperation is essential to discover the early cases or at least many of those still in a stage in which treatment may save a great deal of sight

D Having established or at least suspected the diagnosis of glaucoma, medical practitioners are in a position to direct their patients as soon as possible to ophthalmologists or eye clinics for checkups and to cooperate in the treatment by furnishing the necessary information concerning their patients' general health

The result of such an effort would increase appreciably the number of glaucoma patients taking treatment and would lead to a proportionate decrease of blindness

Glaucoma—a Blinding Disease

There is a type of glaucoma—*acute glaucoma*—which has a stormy beginning and runs a stormier and exciting course. It is characterized by excruciating pain in and around the eye, almost complete loss of vision, one-sided headache, nausea, vomiting, dilation of the pupil, and cloudy cornea. Occasionally, the inexperienced physician may think he is dealing with a gastric upset or iritis. Valuable time is lost. And yet the diagnosis is simple, loss of vision, hardening of the eyeball, congestion, and cloudy cornea are pathognomonic of acute glaucoma. Immediate action can save the eye from blindness. There is nothing insidious about this type of glaucoma.

But for every case of acute glaucoma there are about 10 cases of a different type—*simple glaucoma*. This kind of illness sneaks into a patient's eye almost without his knowledge, gradually and almost painlessly robbing him of his sight. This is the type that if not discovered and treated in time causes blindness. It is for the early discovery of this type of glaucoma that the medical practitioner's help is needed. The impairment of vision usually begins in one eye at first. It usually appears around the age of presbyopia or menopause, somewhere between 40 and 50 (at times later), with an occasional blur in front of one or both

eyes and a slight, one-sided headache. The patient experiences some difficulty in reading, sometimes he complains of tearing and at other times of excitement and worry, a few hours spent playing cards or at the movies leave him with an uncomfortable feeling in his eye and blurred vision, or he may see rainbow-colored halos around the lights. Thus dangerously mild course may last a long time (months or even years) before the patient becomes aware of a considerable loss of central vision and of a defect in the peripheral field of vision. Most of the time the loss is not recoverable and, then, the problem is how to arrest further loss of vision.

And now arises the question whether the rank and file of medical practitioners, some of whom have excluded for a long time a routine eye examination from their daily practice, can still master or acquire the essential points that make up the armamentarium for recognizing or suspecting glaucoma.

The answer is definitely "Yes!" It is relatively easy to make a diagnosis of glaucoma in the advanced stage and often not really impossible in the less advanced stage. In both cases such a diagnosis is of considerable value, especially since one eye may be much less affected and may be "caught" at its initial stage when treatment is usually most effective.

Six Points of a Diagnostic Armamentarium for the Medical Practitioner

The proper technic could be acquired in a few hours by attending lectures and demonstrations organized by ophthalmologists of your locality.

1. Measure the acuity of vision. The cause of subnormal vision of one or both eyes must always be investigated.

2. Examine the size of the pupils and their reaction to light. Inequality of pupils or poor reaction to light is not to be ignored.

3. Feel with the fingers whether the eyes are normally soft or hard. One can acquire this "feel" by instruction and practice.

4. Examine each eye with the ophthalmoscope and find out whether the optic disks are pale and excavated.

5. Ask the patient about the occurrence of occasional blurring or clouding of vision, seeing rainbow rings around a distant light, one-sided headaches, discomfort in or around the eyes after movies, excitement, and worry. Inquire whether the patient experiences difficulty in reading in spite of recently prescribed glasses.

6. Ask whether there is a case of glaucoma in the family.

Above all, exercise tact so as not to alarm the patient unduly.

The presence of any one of these points is not sufficient to make a diagnosis of glaucoma, but investigation of all the points will frequently suffice to obtain enough evidence to detect or suspect the existence of glaucoma. Of these points, the technic of ophthalmoscopy is the most difficult part, but even this can be acquired within a few hours' time to a sufficient degree to enable one to see the optic disks in a majority of patients. All one needs is a willing instructor and an electric ophthalmoscope. With a pair of healthy eyes, patience, and ten carefree hours at his disposal, any medical practitioner may acquire the necessary knowledge and skill.

Now that a campaign for early diagnosis of glaucoma is about to be started, ophthalmologists have a splendid opportunity to popularize among medical practitioners the use of the ophthalmoscope, one of the most important discoveries in the field of medicine. Medical practitioners, being always ready to appropriate procedures that improve their diagnostic acumen, will surely not be indifferent to an offer from ophthalmologists enabling them to enrich their knowledge. This being so, the following question arises: Assuming that the problem of prevention of blindness from glaucoma is a serious one and that the medical practitioner agrees that he can play an important role in the present campaign of prevention of blindness from glaucoma, what plan could be suggested to familiarize the rank and file of the medical profession with the "six diagnostic points" enumerated above and their application in daily practice?

Outline for Organizing a Glaucoma Campaign Among Medical Practitioners

1. Form a committee of one ophthalmologist and one prominent medical practitioner (preferably an influential officer of the county medical society) residing in each principal town or district to conduct the local campaign. The aid and sponsorship of the county medical society should also be enrolled whenever possible.

2. The campaign committee should call a meeting of the rank and file of all local ophthalmologists, explain the object of the campaign, and ask their cooperation in presenting to general practitioners a series of lectures and demonstrations on diagnosis of glaucoma.

3. As soon as this is organized, letters and circulars should be sent to all medical practitioners inviting them to enroll for the course.

Groups of five or six men could easily get the necessary individual instruction, if necessary, two or more groups could be taught at the same time in separate lecture rooms

4 Whenever possible the course of instruction should be centered in clinics or hospitals

5 No discrimination should be made against ophthalmologists who are not connected with hospitals or clinics. All ophthalmologists should participate in the campaign of instruction and demonstration. Allow the practitioners to take the course several times if they so desire

The National Society for the Prevention of Blindness, its Committee on Glaucoma, and the New York State Bureau of Services for the Blind, through its prevention of blindness service, are eager to cooperate in every possible way to promote this important phase of the campaign

Summary

1 Every glaucoma patient is a candidate for partial or total loss of sight

2 Blindness from glaucoma is frequently preventable

3 Prevention of blindness is often attainable by (a) an early diagnosis, (b) early treatment, and (c) constant watchfulness

4 Late diagnosis and treatment mean failure in the majority of cases

5 It is better and more economical to prevent blindness than to subsidize the blind

6 *The role of the medical practitioner in this campaign is* (a) to discover or suspect the presence of glaucoma among his patients, (b) to refer them to eye clinics or ophthalmologists, and (c) to cooperate with the latter by furnishing all the data concerning the general health of the patients

Discussion

Dr William A. Groat, *Syracuse, New York*—The outline that Dr Schoenberg has presented which details the general practitioner's part in the prevention of blindness from glaucoma impresses an internist as sound medical practice. I am not one of those who believes that a general practitioner or an internist should feel himself qualified to make the finer differentiations in the special examination of the eye, but I certainly do feel that every internist, practitioner, or student who has been properly taught physical diagnosis should be, and in the main is, qualified

to make as a routine the basic examinations that Dr Schoenberg considers necessary

It might be well to point out that reciprocally the ophthalmologist should be careful not to disparage or discredit these simple routines, carried out with minimum equipment, so useful as a part of a cooperative plan to pick up deviations from the normal as early as possible

The part of a general examiner should be to know the danger signs and to be able to satisfy himself as to the absence of these danger signs in the particular patient. The part of the ophthalmologist is to carry on from there. The ultimate treatment should be a cooperation enterprise

It was a little bit of a shock to me to hear it said that there is so much blindness due to untreated glaucoma or that glaucoma is such an important item in the prevention of blindness. I, therefore, took occasion to inform myself a little bit, and I find that so far as the literature is concerned the general opinion seems to be that it is a matter of 2 to 5 per cent. There is some discrepancy perhaps because of differences of opinion as to just what blindness is and whether it is absolute, economic, vocational, or educational impairment in some degree as classified by the Division for the Blind in the State Department of Social Welfare. However, there need be no serious quibble about this. Slight or partial impairment of vision is a definite handicap to a person who does anything at all. It limits his activities and his pleasures somewhat no matter what his status may be. So far as glaucoma is concerned, acute or chronic, 2 or 3 per cent of blindness is not much as a percentage, but it is altogether too much and causes too much economic loss and suffering in the aggregate not to be an important topic for consideration by the internist, as well as the ophthalmologist

The thing to be worked for is a solution of just what glaucoma is. It seems now to be just a symptom of something deeper and unknown. It is as much the duty of the internist as it is for the ophthalmologist to discover it, and investigational research should point that way. It is nowhere near as valuable to be able to discover glaucoma early as it is to, as an Irishman might say, discover it before it happens. In other words, the true objective is to know how to prevent glaucoma rather than how to treat it. To do this the internist needs to know what glaucoma really is

Dr Harold H. Joy, *Syracuse, New York*—The National Society for the Prevention of Blindness is to be commended on its appointment of Dr Schoenberg as chairman of its glaucoma committee. Dr Schoenberg has been intensely interested in glaucoma for many years, and no one in American ophthalmology is better qualified to carry on this work

The glaucoma problem is one of intensifying importance, for it is probable that its incidence is rapidly increasing. In great part this is due to

the rise in the population age group of those over 40 and to the strain and worry to which a large part of the adult population has been subjected in recent years

I think we all agree that it is of the utmost importance to make a concerted move to attack this problem. To do this it is essential to arouse the interest and get the cooperation of all physicians practicing medicine in adults. It is not a question of converting them into ophthalmologists but of making them glaucoma-conscious.

This need is exemplified in its crudest form by the many instances of improperly diagnosed acute glaucoma. It not only is confused with iritis and even conjunctivitis but with gastrointestinal upsets and other general conditions. In the majority of cases even a cursory examination of the eye would reveal the true condition. If the physician was thinking in terms of glaucoma, such tragic mistakes would seldom occur.

The diagnosis of chronic glaucoma, particularly the noncongestive type, offers many difficulties to the general practitioner. It is probable that relatively few cases can be uncovered by him in the earlier stages in spite of any instruction ophthalmologists may give. However, if he

becomes conscious of the frequency of glaucoma and knows its symptoms, great progress can be made in diagnosing many cases before too much irreparable damage has been done. The six points which Dr. Schoenberg has brought out should, on the whole, be rather easily mastered. This is particularly true of the history, the visual acuity, and the examination of the anterior segment of the eye. I believe that less reliance can be placed on his ability to test the intraocular tension by palpation and that the interpretation of the ophthalmoscopic picture may be confusing to many.

While Dr. Schoenberg is attacking the problem in the right manner in attempting to secure the interest and cooperation of the general practitioner, the role of the medical student, intern, and nurse should not be neglected. In our teaching we should constantly impress upon them the signs and symptoms of glaucoma, its frequency, and the horrible results of mistaken diagnosis.

Whatever effort we as ophthalmologists put into this campaign will be richly rewarded in saving the vision of many who might otherwise end their days in twilight or darkness.

WE MUST LOOK BEYOND TOMORROW

Through our Selective Service Act, we are removing our future husbands and fathers from their sweethearts and wives, we break the ties which form the foundations of the family. The very thought of draft prevents many couples, who want children, from having them. No responsible man wants to turn to soldiering leaving behind a frightened wife expecting a baby. The prospects of life for her and her baby on a soldier's meager pay are terrifying.

Students of our country have been greatly concerned with the possibilities of a declining population in peacetime conditions. The threat of war and possible draft may accelerate this trend, especially among those who are imaginative, sensitive, far-sighted—who under happier conditions would be the first to have families. It is the final indictment of war that both its direct and indirect casualties fall most heavily on "the best people."

It is an established medical fact that the best ages for having children are between twenty-one and twenty-six. After that time, the risks for mother and baby rise rapidly. These young married people, therefore, for their own sakes, for their children's sakes, for the future of this land, must have in these insecure times as much security as is possible to provide. Hesitant husbands and wives should be encouraged to go ahead with their families by assurance from the community that if conception is necessary, mother and baby will receive good medical, hospital, and nursing care before, during, and after delivery.

But more is needed than just care of mother and baby during childbirth. If families must be

broken up because the husband is drafted, because he must seek work in a distant defense project, or because children must be evacuated from some areas—it should be a cardinal rule of social policy that the mother should always remain with her family. She may be both mother and father to her children. She will, doubtless, be able to keep the rudiments of family life strong, to instill courage, to build character and regard for the other fellow, to keep a unity in family living which is so necessary to the future of children and the strength of the United States in the next generation. There are many possible means of keeping a mother with her family. Some have suggested government subsidies to those families who are called upon to pay the cost of crisis in self-denial and sacrifice. The method does not matter nearly so much as the end result—that of keeping families together. We must not repeat the injustices and sufferings which befell families in the last war in this country and which are even now falling upon families in other lands.

We must look beyond tomorrow and the day after that. We must endeavor to bring as much good out of this period of flux as is possible to achieve—better children with better health, better education, better equipment for life. We need more than National Defense, we need a national offensive program to make family living—the very root of national living—stronger, richer, and more enduring. That offensive can begin in keeping the rudiments of family living strong in this crisis. That should be one of our own peacetime aims.

—Maternity Center Briefs

RECENT ADVANCES IN GYNECOLOGIC HORMONE THERAPY*

SAMUEL H. GEIST, M.D., and UDALL J. SALMON, M.D., New York City

IN RECENT years the chemists have made amazingly rapid progress in isolating and synthesizing a whole series of hormones. A number of these compounds have been employed successfully in the treatment of a variety of endocrine disorders. Others seem to be chiefly of academic interest, appearing, at present, to have little therapeutic value. Unfortunately, clinical endocrine research has not been able to keep up with the hormone chemists, so that, at present, clinicians are in the anomalous position of having available a number of pure hormone products of high potency without knowing how to apply them clinically. Moreover, the nature of the basic endocrine disturbances underlying many functional gynecologic conditions is still but imperfectly understood, and for this reason much of hormone therapy is still more or less empiric or based upon theoretic concepts. To the clinician who has to cope daily with the practical problems of correcting disorders and relieving symptoms, the academic discussions of rationale are only of secondary importance. His chief interest is in therapeutic efficacy. We shall, therefore, confine our presentation to the recent advances in gynecologic endocrine therapy that have proved effective and, in addition, present to you briefly some phases of hormone therapy that are still in an experimental stage but that are potentially of practical value.

Recent Advances in Estrogen Therapy

Clinical Considerations—Estrogens are now universally accepted for the treatment of the

menopause syndrome, whether natural, surgical, or induced by x-ray. No other phase of endocrine therapy has a more logical rationale. It is common knowledge that in this syndrome the basic hormone disturbance consists of an estrogen deficiency. This leads to a variety of symptoms that manifest themselves with varying intensity and emphasis on various systems in different individuals. Although, in the majority, vasomotor symptoms usually are predominant, in many instances other systems bear the brunt of the disorder. Thus, gastrointestinal, urinary, cardiovascular, neurologic, or psychiatric symptoms may dominate the clinical picture, either singly or in various combinations. Many of the functional disorders that were traditionally classified as "neurasthenia" and, currently, as "psychosomatic" are attributable to an estrogen deficiency. More and more evidence is accumulating which indicates that the estrogens have a much more fundamental role to play in the economy of the body as a whole than has hitherto been appreciated. There is both clinical and experimental evidence that suggests that disturbances of liver function and gastrointestinal disorders, as well as functional cardiovascular disturbances, may be related to derangements of sterol hormone metabolism.

Although recent endocrinologic studies have demonstrated the somatic basis for the menopause symptomatology, one should not lose sight of the fact that parallel with the endocrine imbalance many of these patients have emotional disturbances that may intensify or prolong the somatogenic symptoms. This is particularly important when one attempts to evaluate the efficacy of a therapeutic measure in these cases. The therapeutic end point varies in different patients, as well as in the same patient, at different times, depending upon their emotional status. A proper evaluation, therefore, of the effectiveness of a therapeutic agent should consist of a composite appraisal of the objective evidence of efficacy (e.g., hormonologic and morphologic data), as well as of the patient's emotional makeup.

With regard to objective diagnostic methods, it is worth remembering that the studies of Papanicolaou and Shorr^{1,2} have

made available for us, in the vaginal smear, a method to determine whether an estrogen deficiency is present. The finding of definite evidence of the deficiency in a patient enables one to interpret these symptoms more accurately, supplies one with a basis for rational therapy, and leads to a more comprehensive appraisal of the total personality of the patient and, therefore, to a more accurate prognosis. We have simplified the above-mentioned method for determining estrogen deficiency so that this extremely valuable diagnostic procedure can be performed in the office or clinic in a few minutes.^{2,3}

Estrogenic Compounds—It has been established that α -estradiol is the physiologic estrogen normally produced by the ovary. And for clinical purposes this compound and/or its esters, at present, appear to give the most satisfactory results. It has only one disadvantage and that is its costliness.

Numerous studies, both in animals and humans, have demonstrated that the benzoate acid ester of estradiol is absorbed and utilized more slowly than estradiol and, by virtue of this property, is therapeutically more efficient. Recently, another ester of estradiol was prepared—namely, estradiol dipropionate.

Experimental studies in animals have shown that the dipropionate ester of estradiol has a more prolonged estrogenic effect than any of the other estrogenic compounds.^{7,9} Two years ago before this Society we presented a preliminary report on the use of this compound. Since then, we have used it in a series of over 100 patients in varying doses. We have obtained satisfactory therapeutic results with this compound. Morphologic and hormonologic studies performed in these patients have demonstrated that estradiol dipropionate is an estrogen of high potency. It is available in concentrations of 5 mg per cubic centimeter making it possible to administer large doses of estrogens in concentrated form.

Stilbestrol This synthetic compound has, in the past two years, attracted a great deal of attention. Aside from the academic interest in the fact that it is a synthetic compound not related chemically to the natural estrogens, it has enlisted the interest of clinicians because of its high potency when administered by mouth. Another factor that is of great importance is its low cost. It has one disadvantage and that is that it induces unpleasant reactions in some patients. These include nausea, vomiting, epigastric pain,

and dizziness.^{4,5} The incidence of these reactions, according to reports of different observers, varies, ranging as high as 60 per cent.^{5,7} Studies of liver function and of the blood chemistry to date have not revealed the cause of these symptoms.^{6,7,8} Pregnant women appear to be able to tolerate large doses without ill effect.¹⁶ A lively controversy is going on at present as to the advisability of using stilbestrol clinically.

The first report on stilbestrol in America was made before this Society in 1939.⁴ We felt then that since the administration of estrogens constitutes, in the majority of instances, substitution therapy, necessitating treatment for many months and possibly years, the ideal substance for this purpose would be one that most closely approaches the endogenous physiologic hormone. Although we have amplified our studies with stilbestrol, to date we have not found any reason to change our views on the subject. Without losing sight of the importance of making available a therapeutic estrogen of low cost to those of limited means, it seems to us that the primary considerations in the appraisal of a therapeutic agent are its efficiency and lack of deleterious action. Judged by these criteria, stilbestrol is distinctly inferior to the physiologic estrogens. It is to be hoped that further research will result in the elimination of the unpleasant reactions induced by stilbestrol and that the price of the physiologic estrogens will be reduced so that their therapeutic properties will be made available to all in need of estrogen therapy.

Ethinyl Estradiol In our search for an orally effective and inexpensive estrogen during the past year, we have treated a series of 55 cases with ethinyl estradiol.⁹ This compound was prepared by Inhoffen and Hohlweg¹⁰ by the replacement of the seventeenth carbon atom in estradiol by an ethinyl group. The authors report that when given subcutaneously in oil, ethinyl estradiol and estradiol are equal in potency but, when given orally, ethinyl estradiol is fifteen to twenty times as active as estradiol. The use of ethinyl estradiol has been reported in secondary amenorrhea and oligomenorrhea, and proliferative changes have been demonstrated in the uterine mucosa following doses of 56 mg of ethinyl estradiol over a period of twenty days.

Our studies have revealed that this compound is an estrogen of extremely high potency as demonstrated by its estrogenic ef-

RECENT ADVANCES IN GYNECOLOGIC HORMONE THERAPY*

SAMUEL H. GEIST, M.D., and UDALL J. SALMON, M.D., New York City

IN RECENT years the chemists have made amazingly rapid progress in isolating and synthesizing a whole series of hormones. A number of these compounds have been employed successfully in the treatment of a variety of endocrine disorders. Others seem to be chiefly of academic interest, appearing, at present, to have little therapeutic value. Unfortunately, clinical endocrine research has not been able to keep up with the hormone chemists, so that, at present, clinicians are in the anomalous position of having available a number of pure hormone products of high potency without knowing how to apply them clinically. Moreover, the nature of the basic endocrine disturbances underlying many functional gynecologic conditions is still but imperfectly understood, and for this reason much of hormone therapy is still more or less empiric or based upon theoretic concepts. To the clinician who has to cope daily with the practical problems of correcting disorders and relieving symptoms, the academic discussions of rationale are only of secondary importance. His chief interest is in therapeutic efficacy. We shall, therefore, confine our presentation to the recent advances in gynecologic endocrine therapy that have proved effective and, in addition, present to you briefly some phases of hormone therapy that are still in an experimental stage but that are potentially of practical value.

menopause syndrome, whether natural, surgical, or induced by x-ray. No other phase of endocrine therapy has a more logical rationale. It is common knowledge that in this syndrome the basic hormone disturbance consists of an estrogen deficiency. This leads to a variety of symptoms that manifest themselves with varying intensity and emphasis on various systems in different individuals. Although, in the majority, vasomotor symptoms usually are predominant, in many instances other systems bear the brunt of the disorder. Thus, gastrointestinal, urinary, cardiovascular, neurologic, or psychiatric symptoms may dominate the clinical picture, either singly or in various combinations. Many of the functional disorders that were traditionally classified as "neurasthenia" and, currently, as "psychosomatic" are attributable to an estrogen deficiency. More and more evidence is accumulating which indicates that the estrogens have a much more fundamental role to play in the economy of the body as a whole than has hitherto been appreciated. There is both clinical and experimental evidence that suggests that disturbances of liver function and gastrointestinal disorders, as well as functional cardiovascular disturbances, may be related to derangements of sterol hormone metabolism.

Although recent endocrinologic studies have demonstrated the somatic basis for the menopause symptomatology, one should not lose sight of the fact that parallel with the endocrine imbalance many of these patients have emotional disturbances that may intensify or prolong the somatogenic symptoms. This is particularly important when one attempts to evaluate the efficacy of a therapeutic measure in these cases. The therapeutic end point varies in different patients, as well as in the same patient, at different times, depending upon their emotional status. A proper evaluation, therefore, of the effectiveness of a therapeutic agent should consist of a composite appraisal of the objective evidence of efficacy (e.g., hormonologic and morphologic data), as well as of the patient's emotional makeup.

With regard to objective diagnostic methods, it is worth remembering that the studies of Papanicolaou and Shorr^{1,2} have

days, (b) that estrogenic effects on the vaginal mucosa may persist for periods varying from four to fourteen months, and (c) that symptoms may be relieved for periods varying from three to upwards of twenty-two months.

Comparison of Therapeutic Effectiveness of Pellets and Crystals—In the series of cases implanted with pellets of comparable weight and chemical constitution, the physiologic and therapeutic effects were of much shorter duration. In a number of cases in which the pellets were excised, it was found that a fibrous capsule had formed about the pellets and apparently prevented further absorption of the hormone, so that the majority of these patients, several months after implantation, manifested morphologic evidence of estrogen deficiency even though they retained pellets within their tissues weighing as much as 40 mg.

On the basis of these observations we have come to the conclusion that the implantation of loose crystals is far superior to pellets for therapeutic purposes.

Prophylactic Implantation of Estrogens—A series of patients requiring hysterectomy and bilateral ovariectomy was implanted with estrogen crystals at the time of operation, or shortly thereafter, in an attempt to prevent the castration syndrome. The details of this study have been reported elsewhere.⁴¹ The results to date have been encouraging. Many patients have remained symptom-free for periods of over one year. It is obviously difficult to determine accurately the value of this prophylactic therapy, since the incidence of symptoms after surgical castration is variable. Final evaluation will have to be deferred until a much larger series of cases has been studied.

Implantation of crystals of estrogens is undoubtedly the most efficient and economical method of estrogen administration. This form of therapy should be reserved for patients with severe symptoms and with morphologic evidence of estrogen deficiency.

Recent Advances in Androgen Therapy

In the past three years, synthetic male hormone has been used with increasing frequency in the treatment of a variety of functional gynecologic disorders.⁴²⁻⁴⁵ In order to understand the therapeutic *modus operandi* of androgens, it is necessary to know the biologic effects of androgens when administered to women.

Biologic Effects of Androgen Administration in Cyclical Women—The most potent androgen available is testosterone propionate.⁴⁶

If 500 mg or more of testosterone propionate is administered to a woman with a regular menstrual cycle, the following occur (1) gonadotropic activity of the hypophysis is inhibited, (2) follicle growth and ovulation are suppressed, with consequent failure of estrogen and progesterone production, (3) no pregnandiol is excreted in the urine, (4) the next menstrual period is suppressed for four to six weeks, (5) the secretory pattern in the endometrium does not develop, normal proliferation is inhibited, and the endometrium is reduced to a state of hypoplasia or atrophy and (6) the vaginal mucosa undergoes regression and the vaginal smears and biopsies reveal changes indicative of estrogen deficiency.^{47, 48}

In addition to the above, in some patients this dose will induce acne and arrhenomimetic^{49, 50} (masculinizing) symptoms—viz, hypertrichiasis, deepening of the voice, and enlargement of the clitoris. Within a few weeks after discontinuation of therapy, there is a gradual regeneration of the vaginal and uterine mucosa, a restoration of the normal ovulatory pattern, followed by menstruation. The acne disappears within two or three weeks and the arrhenomimetic effects, within several months. In order to induce the aforementioned biologic and arrhenomimetic effects, a minimum of 500 mg of testosterone propionate in one cycle is usually required.

Rationale for Androgen Therapy—It is obvious from the above that androgens counteract or negate the biologic effects of the female sex hormones, and the therapeutic use of androgens in gynecology is based upon this antigynecogenic property.⁴⁹

Clinical Indications and Dosage—*Functional Menorrhagia* Twenty-five milligrams of testosterone propionate, given two or three times weekly, have been found to be effective in the majority of cases of functional uterine bleeding.^{38, 35}

Menometrorrhagia Associated with Fibroids Abnormal bleeding associated with small myomas responds to treatment with testosterone propionate. It has been found, however, that if the menometrorrhagia is caused by a submucous fibroid the therapeutic result is only temporary and, in the majority of cases, excessive bleeding recurs shortly after cessation of therapy.³⁵

Metrorrhagia Associated with Endometriosis The abnormal bleeding responds to androgen administration but is likely to recur shortly after discontinuation of therapy.⁴²

Dysmenorrhea The dosage is essentially

fect on the vaginal mucosa and endometrium and by the relief of estrogen deficiency symptoms. Estrogenic effects in the vaginal smears were noted at the end of five days following an average daily dose of 0.5 mg. Clinical relief of symptoms occurred within four to seven days on average daily doses varying between 0.15 and 0.45 mg. The majority of the patients were kept symptom-free on maintenance doses of 0.15 mg. daily. Ethinyl estradiol was found to be at least ten times as effective as estradiol administered orally.

Eighteen per cent of the cases developed nausea or epigastric discomfort in doses as low as 0.15 to 0.45 mg. per day. These unpleasant reactions, as in the case of stilbestrol, in our opinion detract from the value of this estrogen for therapeutic purposes. This compound, however, deserves further study in order to determine and eliminate the causes of the unpleasant side reactions.

Sublingual Administration of Estradiol in Propylene Glycol Solution—At present, estrogen maintenance therapy is most commonly administered by the oral route. Absorption of estrogens from the gastrointestinal tract is not satisfactory. For instance, judged by vaginal smear reactions, only about one-tenth of ingested estradiol appears to be effective. This makes oral therapy rather expensive. We have, therefore, attempted to administer estrogens through other routes. Estradiol is absorbed through the skin,¹¹ but there are obvious objections to this method. The vaginal route is effective in some patients but is not satisfactory in the majority of parous women, since much of the material is lost from the vagina and many women object to vaginal medication for esthetic reasons.

Recently, we have reported on the absorption of estradiol, in solution in propylene glycol, from the sublingual space.¹² We have found evidence in the vaginal smears of estrogenic effects within three or four days and with surprisingly small doses. In postmenopausal and castrated women with characteristic estrogen deficiency smears, estrogenic effects were noted at the end of one week with daily doses of 0.2 to 0.3 mg. The solution contains 0.5 mg. of α -estradiol per cubic centimeter of propylene glycol. Most satisfactory results were obtained by instilling 4 drops under the tongue and instructing the patient not to swallow for five minutes thereafter. This procedure is repeated several times daily. Once the clinical symptoms are

controlled, the patients have been maintained on as little as 0.1 mg. (1,200 rat units) per day of estradiol.

We have since employed this method of administering estrogens in a series of 42 cases with encouraging results. This method has some objections. It requires the intelligent cooperation of the patient, since the drops must be taken three or four times daily and the patient must be mindful not to swallow for at least five minutes after their sublingual instillation. In some "nervous" patients it is rather difficult to insure observance of these directions. Excessive salivation may interfere with absorption, although medication with atropine controls this satisfactorily. The chief advantage of sublingual administration lies in its effectiveness in small doses.

None of the patients reported any untoward reactions from the propylene glycol. Although a number of experimental studies have been reported in animals and humans attesting to the absence of toxicity of propylene glycol,¹³⁻¹⁵ further studies should be conducted in order to determine what the effect of continued administration would be, before recommending this method for general use.

Implantation of Crystals and Pellets of Estrogens—Two years ago before this Society, we presented a preliminary report on the implantation of estradiol crystals into menopausal patients.⁴ This method of administering estrogens was undertaken to determine whether it was possible to prolong the therapeutic effects of estrogenic hormone and obviate the necessity for frequent injections. Since then, we have implanted over 150 patients. We have attempted to supplement our evaluation of the clinical effectiveness of the implanted hormone by objective methods, viz. (a) duration of pituitary inhibition (as indicated by suppression of gonadotropic hormone production) and (b) duration of estrogenic effects in the vaginal mucosa (as indicated by vaginal smears and biopsies) and endometrium.

For this purpose we have used doses varying from 4 to 50 mg. of estradiol, estradiol benzoate, and estradiol dipropionate in the form of loose crystals as well as compressed pellets. Some phases of this study have already been reported.^{13, 14, 16, 17}

Prolonged Action on Pituitary, Genital Tract and Symptoms—These studies have revealed (a) that by the implantation of estrogen crystals gonadotropic hormone secretion may be suppressed for as long as ninety

role in the normal sex hormone economy of the female

There is considerable evidence in support of this concept. Thus, it has been shown by a number of investigators that normal adult women excrete significant amounts of androgens (26 international units per day as compared to an average of 40 international units per day by men)⁷³⁻⁷⁶ On the basis of these and related observations, the theory of androgen-gynecogen balance has been formulated "In the normal, sexually mature women, gynecogens and androgens are conceived as being in a state of dynamic balance, giving rise to the normal female secondary sex characteristics and normal menstruation. The equilibrium, however, may be upset in one direction or the other. If the gynecogens become dominant, either as a result of a qualitative or quantitative deficiency in androgens or because of an excessive production of gynecogens, the resulting imbalance would be manifested clinically by menorrhagia, metrorrhagia, premenstrual tension, mastopathies, and dysmenorrhea, separately or in various combinations

"If, on the other hand, the androgen influence were to predominate, the clinical picture would consist of oligomenorrhea or amenorrhea and arrhenomimetic phenomena. It is obvious that in such a dynamic system similar biologic and clinical effects may result from an excess of the one as from a deficiency of the opposing factor. It is tempting to accept this theory of a dynamic gynecogen-androgen balance since it appears, at present, to offer a solution to the riddle of functional gynecologic disorders."⁴

Pregnenolone—This compound possesses a unique variety of biologic properties. In animals, it has progestomimetic, some estromimetic, and slight andromimetic action. It is, furthermore, active when administered orally.⁴³

In a series of 20 cyclical women, treated orally with doses varying from 30 to 60 mg per day over periods of one to two months, none of the suppressive (antigynecogenic) effects, which can be so strikingly produced by testosterone propionate and methyl testosterone, were observed. Menstruation was never suppressed and no estrogen deficiency phenomena appeared. Furthermore, in no instance did arrhenomimetic phenomena develop.⁴³

When administered orally to postmenopausal women after adequate priming with estrogens, gestational changes were pro-

duced with doses of 300 to 600 mg, administered over periods of one to two weeks.⁴⁴

In pregnenolone, we have available an orally active substance that has a progesterone-like action. We have found it helpful in some types of dysmenorrhea and in premenstrual tension. It has proved ineffective, in our hands, in functional menometrorrhagia.

The use of pregnenolone has been advocated in the treatment of threatened and habitual abortion.⁴⁵ However, recent studies by Hamblen⁴⁶ shed considerable doubt on the value of progesterone therapy in these conditions.

Recent Advances in Gonadotropin Therapy

Gonadotropins—Ever since gonadotropic extracts have become available for therapeutic use, gynecologists have been interested in attempting to demonstrate gonadotropic effects in humans. Many reports have appeared purporting to prove such effects. Unfortunately, the majority of these reports were solely of a clinical nature and presented no conclusive morphologic evidence of gonadotropic effect on the ovaries. In 1933, Geist⁴⁷ described atretic follicles with hemorrhage in women treated with chorionic gonadotropin. In a carefully controlled study of the effects of gonadotropins on human ovaries, Ross⁴⁸ and Hamblen⁴⁹ failed to find evidence of induced ovulation and reported the finding of regressive changes in these ovaries. Recently, Brown, *et al*,⁵⁰ have described atrophy of the endometrium, in women with normal menstrual cycles, following prolonged treatment with chorionic gonadotropin. In the past two years several enthusiastic reports have appeared describing the production of ovulation by means of the gonadotropin of pregnant mares' serum.⁷⁰⁻⁷¹ We have used three different brands of the same hormone (Anteron—Schering, Gonadogen—Upjohn, Gonadin—Cutter) in a variety of doses, intravenously as well as intramuscularly, but we could not demonstrate to our satisfaction conclusive evidence of induced ovulation. Recently, Mazer and Ravetz⁷² have reported striking gonadotropic effects in the ovaries of women treated with a combination of hypophyseal "synergist" and chorionic gonadotropin (Synapoidin—Parke, Davis). We have noted similar histologic reactions in women following the administration of combinations of hypophyseal "synergist"⁷³ and

* Gonadotropic Factor (Collip)—Ayerst, McKenna and Harrison. Follicle-Stimulating Hormone (Schwenk)—Schering Corporation.

the same as for functional menorrhagia. Satisfactory results are frequently obtained with smaller doses (100 to 200 mg of testosterone propionate) administered during the latter two weeks of the cycle.^{49 57 58}

Ovulation Pain and Bleeding Four to six doses of 25 mg each, given at two-day intervals, beginning on the second to fifth day of the cycle, has proved effective.⁴⁹

Premenstrual Tension Symptoms are almost invariably relieved with 25 mg, two or three times weekly, beginning on the tenth to fifteenth day of the cycle and continued to within two or three days of menstruation.⁴⁹

Premenstrual Mastopathies The swelling, pain, and tenderness usually respond to 10 mg, twice weekly, beginning on the tenth day of the cycle. It may be necessary to increase the dose in some cases. In the majority of the foregoing conditions it has been found advisable to continue administration of the hormone for three consecutive cycles, reducing the dose by 25 to 50 per cent each month.

Postpartum Congestion of Breasts Fifty milligrams daily, for three days, beginning immediately after delivery, have been found effective in the majority of patients.

Safeguards Against Overdosage—Although the threshold for arrhenomimetic effects has been found to be 500 to 600 mg, occasionally one encounters patients who appear to be unusually susceptible and will develop hypertrichosis or acne after smaller doses. The hirsuties is likely to occur in dark-complexioned individuals with an inherent tendency to hypertrichiasis. Likewise, individuals who have had acne may experience a recurrence even with therapeutic doses. Fortunately, the incidence of these complications is so low with the therapeutic dose that the chance of their occurrence need not be considered a deterrent in the use of androgens as therapeutic agents in women.

Value of Vaginal Smears in Avoiding Arrhenomimetic Effects—During the course of our studies it was observed that the vaginal smears would frequently reveal signs of estrogen deficiency before any clinical evidence of overdosage was noted. Making use of this observation, we have found it of value to take vaginal smears weekly during the course of androgen therapy. At the first sign of androgen effect^{29 35} in the vaginal smears, androgen therapy should be discontinued.

The Value of Androgens in the Treatment of the Menopause—Androgens have been found valuable in the treatment of patients with

symptoms of the climacteric, who are still menstruating.⁴⁹ Administration of estrogens to such patients frequently aggravates the symptoms and causes menorrhagia. In these cases, 25 mg of testosterone propionate, twice weekly, are usually helpful in controlling the symptoms.

In addition, there are some menopause patients who are refractory to estrogen therapy. Such patients may show adequate estrogen response in the vaginal smears but remain symptomatically unimproved.⁴⁹ Some of these patients often experience symptomatic relief from androgens.

Oral Androgen Therapy—Methyl Testosterone This compound has been found to be a therapeutically effective androgen when administered by the oral route. Its biologic and therapeutic properties are similar to those of testosterone propionate. It appears to be approximately one-third to one-half as effective by mouth as testosterone propionate is when administered parenterally.⁴⁹ It has also been found to be absorbed in effective amounts when administered by skin incision, but this method of hormone treatment is unsatisfactory.

Sublingual Absorption of Testosterone in Propylene Glycol Solution—We have found that testosterone is absorbed in therapeutically effective amounts if administered sublingually in solution in propylene glycol. The solution contains 25 mg of testosterone per cubic centimeter of propylene glycol. In order to insure absorption of the hormone, the precautions advocated with regard to the use of estrogens in propylene glycol¹² must be observed.

Implantation of Crystals and Pellets of Testosterone and Testosterone Propionate—We have found this method of administering androgens of little value for clinical purposes. While a few patients with dysmenorrhea and menorrhagia experienced good therapeutic results for several months, the majority developed arrhenomimetic symptoms within a few weeks, necessitating excision of the pellets. With the availability of enteral and sublingual methods of administering androgens, it seems quite unnecessary to resort to implantation.

Theoretic Implications of Androgen Therapy—The therapeutic efficacy of androgens in a variety of gynecologic endocrinopathies raises the question as to whether the androgens have a purely pharmacologic action or act as a form of substitution therapy. If we assume the latter, then we are committed to the theory that androgens play a physiologic

role in the normal sex hormone economy of the female

There is considerable evidence in support of this concept. Thus, it has been shown by a number of investigators that normal adult women excrete significant amounts of androgens (26 international units per day as compared to an average of 40 international units per day by men)⁷⁵⁻⁷⁶ On the basis of these and related observations, the theory of androgen-gynecogen balance has been formulated. "In the normal, sexually mature women, gynecogens and androgens are conceived as being in a state of dynamic balance, giving rise to the normal female secondary sex characteristics and normal menstruation. The equilibrium, however, may be upset in one direction or the other. If the gynecogens become dominant, either as a result of a qualitative or quantitative deficiency in androgens or because of an excessive production of gynecogens, the resulting unbalance would be manifested clinically by menorrhagia, metrorrhagia, premenstrual tension, mastopathies, and dysmenorrhea, separately or in various combinations.

"If, on the other hand, the androgen influence were to predominate, the clinical picture would consist of oligomenorrhea or amenorrhea and arrhenomimetic phenomena. It is obvious that in such a dynamic system similar biologic and clinical effects may result from an excess of the one as from a deficiency of the opposing factor. It is tempting to accept this theory of a dynamic gynecogen-androgen balance since it appears, at present, to offer a solution to the riddle of functional gynecologic disorders."²

Pregneninolone—This compound possesses a unique variety of biologic properties. In animals, it has progestomimetic, some estromimetic, and slight andromimetic action. It is, furthermore, active when administered orally.¹²

In a series of 20 cyclical women, treated orally with doses varying from 30 to 60 mg per day over periods of one to two months, none of the suppressive (antigynecogenic) effects, which can be so strikingly produced by testosterone propionate and methyl testosterone, were observed. Menstruation was never suppressed and no estrogen deficiency phenomena appeared. Furthermore, in no instance did arrhenomimetic phenomena develop.¹³

When administered orally to postmenopausal women after adequate priming with estrogens, progestational changes were pro-

duced with doses of 300 to 600 mg, administered over periods of one to two weeks.¹⁴

In pregnenolone, we have available an orally active substance that has a progesterone-like action. We have found it helpful in some types of dysmenorrhea and in premenstrual tension. It has proved ineffective, in our hands, in functional menometrorrhagia.

The use of pregnenolone has been advocated in the treatment of threatened and habitual abortion.¹⁵ However, recent studies by Hamblen¹⁶ shed considerable doubt on the value of progesterone therapy in these conditions.

Recent Advances in Gonadotropin Therapy

Gonadotropins—Ever since gonadotropic extracts have become available for therapeutic use, gynecologists have been interested in attempting to demonstrate gonadotropic effects in humans. Many reports have appeared purporting to prove such effects. Unfortunately, the majority of these reports were solely of a clinical nature and presented no conclusive morphologic evidence of gonadotropic effect on the ovaries. In 1933, Geist¹⁷ described atretic follicles with hemorrhage in women treated with chorionic gonadotropin. In a carefully controlled study of the effects of gonadotropins on human ovaries, Ross¹⁸ and Hamblen¹⁹ failed to find evidence of induced ovulation and reported the finding of regressive changes in these ovaries. We have noted similar histologic reactions in women following the administration of combinations of hypophyseal "synergist" and

* Gonadotropic Factor (Collip)—Ayerst McKenna and Harrison. Follicle-Stimulating Hormone (Schwenk)—Schering Corporation.

chorionic gonadotropin (Pranturon—Scher-ing) The reactions elicited, however, do not appear to be physiologic in character and, in many instances, appear to border on the pathologic In our opinion, such stimulation of the parenchyma of the ovary and the follicular elements is abnormal and does not appear to serve any useful purpose *Until unequivocal morphologic evidence of an orderly gonadotropic action on the human ovary simulating the normal physiologic effect is demonstrated, clinical reports of therapeutic triumphs achieved with gonadotropins should be regarded skeptically* At present, the gonadotropins available for clinical use appear to have little, if any, therapeutic value in gynecology

Summary and Conclusions

1 A brief summary of recent advances in gynecologic hormone therapy is presented In the field of estrogen therapy, the therapeutic effectiveness of the following estrogenic compounds is described estradiol benzoate, estradiol dipropionate, stilbestrol and ethinyl estradiol

2 A preliminary report on the sublingual administration of estradiol in solution in propylene glycol is made

3 The value of estrogen implantation is described

4 Prophylactic implantation of estrogens when removal of both ovaries is necessary is recommended

5 The biologic and therapeutic properties of androgens are described and the value of androgen therapy in the treatment of functional menorrhagia, dysmenorrhea, premenstrual tension and premenstrual mastopathies, and the menopause is appraised

6 The therapeutic properties of an orally effective androgen, methyl testosterone, is described

7 The signs and symptoms of androgen overdosage are detailed and methods for preventing the arrhenomimetic phenomena are described

8 The biologic and therapeutic properties of pregnenolone, an orally active progestomimetic compound, are described

9 The therapeutic value of the gonadotropic hormones is briefly reviewed

NINE OUT OF EVERY TEN YOUTHS IN NYA POSSESS HEALTH DEFECTS

"While about 80 per cent of the young people employed by the National Youth Administration are fit for any type of work, nine out of every ten have health defects, most of which can be remedied provided suitable treatment is made available, according to preliminary statistics compiled under the health program of the National Youth Administration," a report in the Medical Preparedness Section of the *Journal of the American Medical Association* for May 31 states.

"These figures are based on the results of medical examinations of 10,000 NYA workers made by local practicing doctors and dentists who have been employed by the National Youth Administration to do this work. The records tabulated to date reflect the health needs of youth as seen by physicians from twenty-one states representing all geographic regions of the United States.

"With the cooperation of the medical profession as well as of federal and state health authorities, the National Youth Administration's health program now operates in all states. The basis of this health program, which is an important part of the defense work of this agency, is a medical examination which facilitates assignment of youth to suitable work activities and at the same time discloses to young people their need for remedial treatment.

"While the primary aim of the NYA is to provide young people with basic work experience to fit them for jobs in private industry, it has a logical concern with building up the health and physical fitness of its employees, both from the standpoint of the national welfare and as the largest employer of youth labor in the country.

"Dental care was recommended for 56 per cent of those examined. This is made up of recommendations made by both physicians and dentists. If dentists had been used to make the dental examination for each youth, the figure would have been considerably higher, since among youths examined by dentists 72 per cent were reported as having carious teeth, while physicians reported only 47 per cent.

"It is of interest that, in 10 per cent of the youth, each had from ten to thirty decayed teeth.

"Tonsillectomy [surgical removal of the tonsils] was recommended for 15 per cent.

"Refraction [of the eyes] was recommended for 15 per cent.

"Special diets were recommended for 10 per cent.

"Minor surgery was recommended for 2 per cent.

"Venereal disease treatment was recommended for 2 per cent. If a youth is already under treatment for a venereal disease, many physicians do not recommend treatment in this type of examination, although they do note presence of the disease.

"Major surgery was recommended for 2 per cent.

"Hookworm treatment was recommended for 2 per cent. Considering youth from the southern states only, treatment for hookworm disease and hookworm infection was recommended for 5 per cent.

"Slightly over 5 per cent were described as being malnourished, while obesity was present in 3 per cent.

"Organic heart disease was reported in almost 3 per cent of those examined.

"In this first group to be reported, tuberculin testing and chest roentgenograms had not been completed, however, 95 cases of pulmonary tuberculosis were reported, of which 26 were active.

"The eight leading health defects for which corrections have been recommended can largely be taken care of in clinics or offices of physicians and dentists. Only a small group need hospitalization. Most of the health defects noted do not affect, at this early age, the ability of approximately 80 per cent of these youth to work, but many of the defects will influence unfavorably the selection of many youths by private industry and will, at a slightly later stage of life, decidedly affect the efficiency of the individual on any job, as well as eligibility for military service."

MULTIPLE NECROTIZING SKIN LESIONS IN CHRONIC ULCERATIVE COLITIS

JOSEPH FELSEN, M D, New York City

THE following report is of interest because of the unusual character of the complications in chronic ulcerative colitis. There occurred during the exacerbation phase of a previously existing chronic ulcerative colitis multiple areas of skin necrosis, generally discrete but sometimes confluent, often appearing in successive crops, rapidly progressive and distinctly phagedenic in character. The distribution of the lesions was chiefly over the chest, abdomen, buttocks, back, and extremities. Starting as a small, painful, reddened papule, there was exhibited within approximately twenty-four hours a central zone of necrosis and pus surrounded by a dark red, angry-looking halo that gradually tapered off into the surrounding normal-appearing skin. In all instances the floor of the ulcer was formed by muscle or fascia, the general picture resembling that seen in *Bacillus histolyticus* infection where massive necrosis and dissolution of tissue occur almost overnight. In our patients, however, the necrosis did not involve the muscle. The lesions described were usually widely separated and discrete but sometimes continued to advance rapidly until contiguous ulcers (5 by 5 and 5 by 10 cm. in 1 case) were separated by a bridge of 7 cm. of intact skin, which, however, was completely undermined and finally broke down to form a single large confluent ulcer. Multiple fresh lesions appeared, varying in size, shape, and stage of development, as long as there was evidence of progressive pathology. With healing, soft pink granulation tissue covered the floor of the ulcers and delicate bluish epithelium grew from the margins of intact skin. Occasionally, temporary regression took place, portions of the young epithelium becoming necrotic. In general, advancing skin lesions were concomitant with the height of intestinal pathology and healing was synchronous with subsidence of intestinal symptoms and signs. The end result was a slightly depressed, dimpled, round or oval scar at the site of each ulcer, often with a marginal area of brownish pigmentation.

In no case were the necrotizing skin lesions ever present during the remission phase or in previous exacerbations of the chronic ulcerative colitis.

Besides the rapidly necrotizing character

of the skin lesions, two striking features were the depth and extension of subcutaneous involvement. Indeed, in some areas healthy-appearing skin adjacent to an ulcer was seen to be totally undermined with subsequent death en masse. This was particularly manifest in Case 3 in whom a deep cellulitis of the cervical tissues occurred with final breaking down of the overlying skin and subcutis, producing an immense ulcer covering the right side of the neck and upper anterior aspect of the chest.

We have seen the sternocleidomastoid, biceps, trapezius and gluteus maximus laid bare in part by these rapidly progressive, histolytic, or phagedenic ulcers. While most of them occurred in hairy regions, in Case 1 they also involved the cornea and conjunctiva. The time of healing varied from approximately one week in the case of small discrete ulcers to several months for the largest ones. Cultural studies revealed *Bacillus coli*, *Staphylococcus aureus*, and a nonhemolytic streptococcus in Cases 1, 2, and 3, respectively. No anaerobic organisms were recovered.

Case Report

Case 1—E. W., a single woman, aged 22, referred by Dr. Samuel C. Levine, was admitted to the Bronx Hospital on April 11, 1939. Approximately four months previous she had begun to complain of frequent abdominal cramps and bowel movements. These increased in severity with minor remissions until frank blood and pus were noted in the stools. There was marked anorexia and loss of weight. At the time of her admission she exhibited the characteristic symptoms and signs of a severe chronic ulcerative colitis in the exacerbation phase, with frequent watery, purulent, and bloody diarrheal discharges. The major pathology in the bowel extended from the cecum to the sigmoid, with somewhat lesser involvement beyond this point. The blood revealed an agglutination titer of 1:320 against Flexner Y, and dysentery bacteriophage was found in the feces. Toxic systemic manifestations with articular or periarticular involvement, chiefly of the upper extremities, were prominent clinical features. A number of discrete, deep necrotic ulcers were present over the buttocks, trunk, and lower extremities. Successive crops appeared until sixteen were present, varying somewhat in appearance depending upon their stage of development. In

general, each was surrounded by a dark red hemorrhagic halo and was exceedingly painful to the touch. The skin, arthritic and general toxic manifestations appeared to reach their peak when the intestinal infection was at its height. The temperature was 104.5 F with gradual decline to 101 F. Six blood counts revealed leukocytes totaling 17,400 to 22,500 per cubic millimeter, with segmented forms varying from 56 to 80 per cent and nonsegmented forms from 1 to 22 per cent. With recedence of the colitis the other symptoms and signs gradually disappeared and the temperature fell to normal. She was discharged on May 2, 1939. On December 10, 1939, she was admitted to Mt Sinai Hospital* because of recurring symptoms. The clinical course was similar to that just described. The skin lesions were distributed over the left leg and left side of the trunk. In addition, there was an ulcer of the left cornea, above the limbus, which progressed rapidly with formation of a deep slough extending toward the center of the cornea. Simular ulcers developed in the right upper palpebral conjunctiva. Both the corneal and conjunctival ulcers were poorly vascularized, the tissue appearing to have "just melted away." The temperature varied from 99 to 103 F and there were four to eight fluid bowel movements daily. The blood count was as follows: hemoglobin, 75 per cent, leukocytes, 16,000 per cubic millimeter, polymorphonuclear neutrophils, segmented forms 16 per cent, nonsegmented forms 44 per cent, lymphocytes, 24 per cent, mononuclear cells, 10 per cent, eosinophils, 3 per cent, plasma cells, 3 per cent. There was marked toxic granulation of the polymorphonuclear cells. Healing of the necrotizing skin lesions was again synchronous with subsidence of intestinal symptoms and signs. Cultures of the pus in the ulcerated areas revealed *B. coli*. Anaerobic cultures were negative.

Case 2—J. D., a married man, aged 35, was referred by Drs Frank M. Frankfeldt and David Zahn. In July, 1937, the patient, his wife and child were involved in a hotel outbreak at Rockaway Park, Long Island, characterized by abdominal cramps and diarrhea. Almost all of the residents were affected. While no accurate data are available regarding the nature of this outbreak, it occurred in an endemic area of bacillary dysentery, and the incubation period and clinical picture were highly suggestive of the disease. Three months later there was a recurrence of symptoms in the patient and his wife, bloody movements occurring in both, the latter being affected for two weeks. Since then the patient has suffered from repeated attacks, increasing in severity and duration. On May 14, 1938, the time of his first consultation, sigmoidoscopy revealed the typical picture of chronic ulcerative colitis. This period corresponded to that noted in the follow-up studies of the Jersey City epi-

demic of Flexner dysentery, 10.7 per cent of the patients developing chronic ulcerative colitis or distal ileitis by the end of 9 to 12 months.¹ Of further interest in this connection is the recent recurrence (December, 1940) of bloody movements in the wife and diarrhea in the child. Under appropriate treatment there was an apparently complete recession of the ulcerative colitis in the husband without any evident signs of pseudopolyposis, intramural fibrosis, or luminal stenosis. In the spring of 1940 the patient had a serious infection of both middle ears eventually necessitating bilateral mastoid operations. He ran a stormy clinical course with a poor general physical state as an aftermath. During this time, signs of recurring intestinal manifestations were noted which appeared to yield temporarily to neoprontosil, which was being used for treatment of the ear infections. Within a few weeks, however, the ulcerative colitis reappeared in a much more aggravated form than ever before. It was at this time that the multiple, focal, or discrete ulcers appeared, chiefly on the face, chest, lower extremities, and neck. New lesions were noted almost daily during the height of their evolution. Necrosis was rapid and deep and on the anterior aspect of the chest a large geographic denudation of the skin was produced, measuring approximately 15 by 10 cm. in size. This was produced by the confluence of two rather widely separated, but rapidly spreading, ulcers, which gave the impression that the skin was melting away. The intervening normal appearing skin was completely undermined for a distance of approximately 7 cm. before breaking down. The pectoral muscle fibers could be discerned. With subsidence of the intestinal symptoms and signs the ulcers healed rapidly, leaving slightly depressed dimpled scars. On December 13, 1940, the ulcer on the chest and another on the right thigh were still present but were almost completely epithelialized. It is of interest that at the height of the recurring colitis, when massive intestinal hemorrhages occurred, small focal areas of necrosis were noted in the advancing edge of marginal epithelium. A culture of the pus bathing the ulcerated areas disclosed a *Staph. aureus*. The blood culture was negative.

Case 3—N. S., a single man, aged 20, was referred by Dr Alfred M. Wise. In March, 1934, the patient noted bloody stools for the first time, accompanied by indefinite generalized abdominal discomfort. Recurring attacks increased in severity and duration until July 6, 1934, when the patient was seized with severe right lower quadrant pain accompanied by bloody, diarrheal movements. On July 8 the temperature rose to 105 F, and a laparotomy was performed by Dr J. Landy with a presumptive diagnosis of acute appendicitis. The findings were a severe ulceration of the entire colon with a rather doubtful involvement of the appendix. The patient was subsequently treated at two other hospitals for chronic ulcerative colitis with no appreciable

* I am indebted to Dr. George Baehr for the follow-up data in this case.

effects On September 8, 1940, following an attack of sore throat, there developed a severe cellulitis with lymphadenitis on the right side of the neck With it there was an increase in intestinal manifestations The cervical infection advanced rapidly with marked dissolution and necrosis en masse of the overlying skin until a single, large, ulcerated area covered the entire right side of the neck and upper third of the anterior aspect of the chest The floor was formed by the muscles and fascia of the neck and chest Healing of this ulcer proceeded steadily with beginning recession of intestinal symptoms At the time of consultation on December 20, 1940, several discrete healed ulcers were present in addition to the large area, described above, which was still denuded to a size of approximately 15 by 20 cm A nonhemolytic streptococcus was recovered from the area of cervical cellulitis, throat, and feces Anaerobic wound cultures proved negative Blood cultures were also negative

Therapy and Comment

The therapeutic procedures that appeared to be most helpful may be summarized as follows, starting with those of greatest effectiveness

1 Repeated whole blood transfusions, more particularly from a donor immunized with dysentery-colitis vaccine² More recently, I have had comparable results in severe toxic cases of chronic ulcerative colitis by the repeated use of polyvalent desiccated (lyophil) plasma (Sharpe and Dohme) Its use was predicated upon the assumption that some degree of passive immunization was afforded by the intravenous or intramuscular injection of pooled homologous plasma fractions of the blood from 25 to 50 donors Other advantages were availability without the necessity of blood grouping, compatibility or Kahn tests, the reported adequate preservation of antibodies and complement by the lyophil process, and control of plasma concentration The last consideration is of some value in hypoproteinemias and nutritional edema, conditions sometimes encountered in chronic ulcerative colitis Where profuse intestinal hemorrhage and anemia are present, whole blood supplemented by plasma transfusions may prove more effective than either used alone

2 High-vitamin diet supplemented by oral and parenteral administration of large amounts of synthetic vitamins, particularly B complex, C, and A

3 Intestinal oxygenation³

4 The local use of sulfathiazole powder dusted upon the ulcerated area A 2-per cent

alcoholic solution of gentian violet applied locally occasionally aborted an early lesion.

5 Sulfonamide (sulfathiazole, neoprontosil, sulfanilamide) medication. These should be used with great caution since, in addition to the known toxic manifestations, I have occasionally noted hemorrhagic necrosis of the intestinal mucosa following their administration

6 Local dressings of boric acid ointment are applied thickly to protect the granulating areas and borders of epithelization. Frequent exposure of large ulcers to the air or sunlamp also appears to favor healing

The pathogenesis of the peculiar necrotizing skin lesions can only be surmised from a careful study of the clinical aspects of the cases described It appears quite evident that a single bacterial agent is not involved, since cultures revealed different organisms in each instance The general clinical features indicate a close relationship between the skin lesions and exacerbation phase of the intestinal infection, since the former were never seen in the remission phase when the patient's general health was at a relatively high level We have previously pointed out that the exacerbation and remission phases of chronic ulcerative colitis often corresponded to low and high degrees of immunity⁴ While this statement was predicated to some extent upon serologic studies, the limitations of such studies are well recognized⁵ However, many clinical observations lend support to this view, since recurring attacks of ulcerative colitis are often precipitated by unrelated extraenteric infections such as those involving the upper part of the respiratory tract Once the exacerbation phase develops there occurs a rapid undermining of the nutritive economy due to a vicious combination of anorexia, frequent bowel movements, and toxemia The result is a state of nutritional imbalance involving excessive loss of body fluids, salts, vitamins, fats, and other elements at a time when they are most needed to enable the body to combat the intestinal infection Their adequate replacement is essential for the maximum immunologic response involved in recovery One of the most important components appears to be the vitamins The deficiency is of the multiple vitamin type (A, C, and B complex) With adequate replacement, prompt resolution of the skin lesions occurred in our cases, but not until the intestinal infection also began to recede Therefore, we feel that while the skin ulcers appear to be due largely to a vitamin deficiency with

poor tissue resistance both are essentially secondary manifestations of the ulcerative colitis. The necrotizing lesions have been seen thus far only in the severe forms of chronic ulcerative colitis. Their rarity is attested by an incidence rate of less than 0.3 per cent in my series.

Summary

Necrotizing phagedenic skin lesions occur

as a complication of severe forms of chronic ulcerative colitis. They appear to be associated with loss and inadequate replacement of the essential nutritive elements of the body, particularly vitamins.

PUT THE DOCTOR ON A PAR WITH OTHER CREDITORS

The average run of citizens who take automobiles to a garage for overhauling or repairs do not expect to recover their property until they have paid the mechanic's bill. How different is their attitude toward the doctor's indebtedness!

The doctor is mechanic, engineer, and all-around repairman for the ailing human frame, yet he rarely gets paid when his work is done. According to an editorial some time ago in *America*, the Metropolitan Life Insurance Company made an interesting survey among its millions of policyholders. The survey reports that the average annual payment of the average family to its physician was \$140. Only the doctor himself knows when and after what delays this sum was finally paid to him.

The commentator says wisely: "Now the cost of repairing the human machine engenders one of the most interesting problems of the day. It is a most important factor in the family budget. From very many parts of the country the report has come that after the bill for medical services has been rendered, the family physician, who floated into the house with healing upon his angelic wings, assumes the menacing part of a Shylock."

"That medical, hospital, and surgical fees do impose a terrific burden upon some families is beyond all question. To many a man working for a salary, the physician's order to go to a hospital for an operation is worse than a decree in bankruptcy. It means, in many instances, the loss of his job, and a period in which bills pile up so high that he must work for the rest of his life to pay them."

"This fact is recognized by the professional. For several years medical, surgical, and hospital committees have been surveying the field, and as they are animated by an honest purpose we can rely upon an accurate and intelligent diagnosis of a very serious social problem. But it has already become apparent that the reason for many a heavy hospital bill is the fact that the patient and his family have demanded unnecessary, and even luxurious, accommodations and special service. Even when they are sick, some people never lose their ambition to keep up with the family of Jones."

"One aspect of this problem should not be lost sight of. If some physicians demand, and collect exorbitant fees, others never receive the modest fees which they ask. Every profession has its list of nonpaying clients, but the physicians probably have the longest catalogue. Men who have been snatched from what Mr. Toots would designate the Cold and Silent Tomb are so jubilant that they are quite unable to think of anything so prosaic as a bill for professional services rendered. Besides, now that the crisis is safely passed, they are too busy arranging a trip to Europe."

"Most families have a tale of the Exorbitant Physician. There is such a creature. But there is also the physician who comes home tired out after a long day, to wonder where he can scrape enough money, together to meet his office rent. In his behalf, we would urge the Divine, sanctioned by all law, human and obligation, to pay one's debts as promptly as possible."

—*Illinois Medical Journal*

The Nueces Valley District [Texas] Dental Society, composed of thirty-three members, has an organization which is called the "Chicago Club," in which each member pays one dollar per month and at the end of the year numbers are drawn allowing two winners. These two winners divide the money to pay their expenses to the Chicago Dental Midwinter Meeting for that year. They are obliged to bring detailed reports of the meeting to the Society.

Great longevity without health is much more than an individual tragedy. Contrariwise, increased longevity can be made an incalculably valuable asset to the commonwealth if the potentialities of the elderly are wisely guided. A period of intellectual conquest may be dawning. Man at last will live long enough to have time to think.—Dr. Edward J. Stieglitz, consultant in gerontology, National Institute of Health, Bethesda, Maryland.

SODIUM PHOSPHATE IN THE TREATMENT OF DIABETES

A Clinical Study

BARNET JOSEPH, M D , New York City

SODIUM phosphate is a preserver of muscular energy. This was first demonstrated by Embden, and the salt was administered on its largest scale to the fighting personnel of the German Army during the War of 1914-1918.

Since then considerable evidence has accumulated to prove that sodium phosphate in submaximal doses can retard muscular fatigue and exert a benign influence on the metabolism of the body.

I began its use as a therapeutic agent against the complaint of "weakness" in 1920. Among those who were placed under this treatment were several diabetic patients in whom weakness was a persistent complaint. It was soon observed that under this therapy the glycosuria of the latter became reduced, that their general well-being was distinctly elevated, and that they could tolerate an increased carbohydrate intake without materially increasing the amount of urinary or blood sugar.

In the first few years of insulin I did not discontinue the use of sodium phosphate for most of my diabetic patients who either refused or were in no position to undergo the hormonal treatment. In 1925 one of our patients who had been using insulin (about 20 units daily) for four weeks went into insulin shock, followed by mild delirium, one hour after what would today be estimated at about a 20-unit dose. She was a woman aged 54, with diabetes of four years' standing, who was careful of her diet even while taking sodium phosphate. Following the shock-effect, she refused to take any more insulin and was not seen for several months. She continued to feel well on the now more liberal diet but was taking more sodium phosphate.

That it was the sodium phosphate that intensified the action of insulin in the first case was demonstrated a year later when another of my diabetic patients (a woman, aged 50, with diabetes for three to four years) had a similar accident, under almost exactly the same conditions as obtained in the one previously mentioned. Thereafter, proof of the synergistic action of sodium phosphate to insulin was made manifest in increasing numbers, the case herewith recorded being a common occurrence.

Case Report

S. R., a moderately diabetic woman, aged 48, (first blood sugar 260, now 140-190, first urine $4\frac{1}{2}$ per cent, lately 0.5 to 1.3 per cent) shows a comparatively sugar-free urine when she uses 10 units of insulin before dinner, three times a week, and 2 Gm. of sodium phosphate a day. Therapy in this case was begun with 30 units of insulin divided in 3 *ante cibum* doses, and 3 Gm. of sodium phosphate daily. At the end of ten days, the urine was sugar-free and the blood content on a fasting stomach was 150. The insulin was then brought down to 20 units, which occasionally had to be remitted because of evidence of hypoglycemia in spite of a satisfactory diet. Four weeks later insulin was established at 10 units once a day. Mild insulin shock occurred two hours after the last meal of the day under the uninterrupted use of the 10-unit dose for fifty-eight days. She was taken off the daily insulin and the dosage of the sodium phosphate was made more frequent, but still, at the end of another week of treatment, there was evidence of shock after the fifth successive insulin injection.

Since that period (four years at this writing) this patient feels comfortable under 10 units every other day if she takes the sodium phosphate, otherwise it becomes necessary to increase the insulin to 30 units a day, for at least six days, in order to keep her urine sugar-free. Without the sodium phosphate for a few days and even with her full complement of insulin, this patient complains of weakness and nervousness.

It is because many diabetic sufferers are in no position to receive insulin injections according to directions and, as a consequence, are but inadequately treated that I have used sodium phosphate as an additive treatment in 104 diabetic patients (46 men) during a period of twelve years. Of that number I have reason to believe that only about 30 per cent are consistent users of insulin as directed.

To prove the status of this salt in sugar metabolism, sugar tolerance tests were conducted on 12 nondiabetic patients (whose blood sugar content was slightly over 120 on the fasting stomach) who were all past the age of 40, on 14 with higher sugar levels in their blood, and on 8 diabetic women under insulin control. From eight to twelve days after the administration of sodium phosphate, retesting

for sugar tolerance showed that close to 90 per cent had an increased sugar tolerance on the test days ranging from about 20 to over 90 per cent. As is to be expected the non-diabetics gave the better figures.

Twenty-four of the more moderately diabetic patients under the simultaneous administration of phosphate of soda and insulin increased their carbohydrate intake (including such foods as ice cream and chocolate) from one-fifth to one-third of their usual allowance without any perceptible effect on the blood sugar content or urinary sugar excretion.

Pruritis is one of the most common first complaints of hyperglycemia. The word "hyperglycemia" is used advisedly, since many of these patients at first have but few of the classic symptoms of diabetes. It was the chief complaint in 83 out of 604 diabetic patients observed in the past twenty-six years. It was present as a secondary complaint in 48 and occurred at one time or another in 84 others.

In this class of patients the blood sugar content is invariably higher than the urinary sugar. In fact, the arbitrary ratio that I have been able to establish among my private patients (1 in the blood to 1.5 in the urine) is more than reversed in patients whose chief complaint is pruritis.

Four of these patients (3 men, 1 woman) showed, respectively, at the first examination blood sugar, 4.6, urine, trace, blood sugar, 3.3, urine, 0, blood sugar, 5.1, urine, 0.2 (woman), blood sugar, 2.5, urine, trace.

Virtually all of the more severe cases of pruritis when first seen presented evidence of marked focal infection or had recently overcome an infection or suffered for a long time from a chronic focus, especially in the sin-

Prior to the advent of insulin, the customary mode of the treatment of pruritis due to hyperglycemia was the immediate deprivation of all forms of sugar, the reduction of starches, and the administration of bicarbonate of soda. Success depended a great deal on the treatment of any focus of infection. The results varied from fair to poor.

Better results followed the addition of sodium phosphate to the above treatment but was partially discarded in a number of patients when it was discovered that insulin worked far more rapidly than any other form of treatment. In fact, insulin is almost an immediate specific in pruritis. However, where insulin was not immediately available,

sodium phosphate alone gave us better results than any other form of therapy.

Two of the most common complaints of the undertreated diabetic patient are dryness of the mouth and dull headache. Sodium phosphate seems to act almost as a specific in the relief of these complaints. An outstanding example of this action of the salt was demonstrated in one of our patients (Mrs. S., aged 49, a rather severe diabetic sufferer of fifteen years' duration) who averages 40 units of insulin a day with sodium phosphate but 60 to 80 without this salt. While on a cruise she found herself without insulin and could obtain none for forty-eight hours. Dryness of the mouth and headache became intense in twelve hours. The dryness was not relieved by copious draughts of water, although the headache was somewhat modified by acetyl salicylate.

The ingestion of approximately 2 Gm. of sodium phosphate in divided doses gave relief from the dryness in about eight hours, while the headache disappeared entirely. The appetite, which failed from the first omission of the insulin, now returned.

In the past eight years 44 of the 104 diabetics (of whom 81 were women and on whom these observations are built) "juggle," so to speak, their insulin with the sodium phosphate. Some who are on doses of 10 units a day or under sometimes give up the insulin in favor of the phosphate for weeks at a time, the criterion being the reappearance of traces of sugar in the urine.

Two female patients, aged 38 and 46, respectively, with rather severe diabetes (first blood content in both, 4.8 per cent) and under insulin for years, went over six weeks at one time and nearly eight weeks at another without insulin but on sodium phosphate. In both periods and on an unchanged diet, there was only a moderate increase in the blood sugar, while urinary sugar occasionally ran up to 4 per cent in one and 2.8 in the older patient. No acetone or diacetic acid could be ascertained in fourteen examinations of the urine in each of both periods.

Moderate mildly diabetic patients under sodium phosphate treatment not uncommonly cut their insulin treatment down to a third or less for long periods at a time, none, however, to the best of my knowledge, ever developed acidosis if they were careful not to go beyond certain limitations.

One man, aged 50, known to have had diabetes with hypertension for about four years, can get along with 10 to 15 units of

TABLE I

	1st Following Morning	2nd	3rd	4th	5th	6th	7th
Average blood sugar content on fasting stomach of first noninsulin day—2.1%	2.4		2.8		2.4	2.4	2.6
Average sugar in urine collected 24 hours of the last day of insulin—0.3%		1.4	1.5	1.4	1.5	1.6	1.6

insulin a week while taking sodium phosphate, but he requires 10 daily units without the salt. In this case, in spite of a more liberal diet, hypoglycemia symptoms develop after six consecutive daily 10-unit doses of insulin if he takes the sodium phosphate at the same time.

In the course of the past twelve years, 24 ambulatory diabetic patients—selected because of recent onset of symptoms, closer age period, and for presumed reliability in following orders—cooperated in tests to prove the effects of sodium phosphate on their blood and urinary sugar contents while still on increased diets but without using insulin. The test period was of eight days' duration, 33 others who underwent the insulin deprivation for the same length of time had urinary tests only. All patients (of whom 48 were women) had exactly thirty days of insulin treatment (average 30 units per day), and none had taken sodium phosphate prior to the first test. The average age was 44. The average presumable date of onset of symptoms was barely more than two months, the average first blood sugar content was 3.35 to 3.5, the average urinary content, 4.2. No patient took less than $2\frac{1}{2}$ Gm. or more than 3 Gm. of sodium phosphate a day during the test period. All blood tests were made on the fasting stomach, the urine consisted of mixed small quantities of each voidance in twenty-four hours. The individual variations were negligible and are omitted from Table 1.

On their own initiative, 14 patients continued the therapy for several days more, 6 of them for as long as two weeks, and 2 others for as long as three weeks. No further tests, however, were performed except on the 2 patients who went without insulin for three weeks. In these and on the day prior to the reinstitution of insulin the blood sugar content was 2.8 and 2.6 per cent, respectively, their blood sugar at the first visit was 3.85 and 3.2 per cent, respectively, and at the end of the first eight-day series of tests the blood sugar was 1.4 and 1.6 per cent, respectively. The last urinary examination made on the last day of their noninsulin therapy showed a sugar content of 1.8 and 1.2 per cent, respectively.

All were free from symptoms and several

TABLE 2

	2nd Day	3rd	4th	5th	6th	8th
Blood	1.6		1.6		1.8	1.8
Urine	0.4	0.4	0.6	0.62	0.7	0.64

expressed the satisfaction of not having to take hypodermic medication. So similar were the conditions in the patients selected for the tests that the individual variations never went beyond 20 per cent above or below the average established for the group as a whole.

Eight of the above group (all women) were retested six months after the first study (average blood sugar content was 1.5, urinary sugar was 0.3 before being taken off the insulin) in exactly the same manner as on the prior occasion, and Table 2 gives the average of a week.

To prove whether sodium phosphate had the same muscular energizing effect in diabetic, as in nondiabetic, patients, all were, at various times, requested to note the effects on their physical capacity under nearly identical physical conditions as season, diet, exercise, etc., under insulin alone, under sodium phosphate alone, and in a combination of the two. Few knew the name of the salt, the information being withheld in order to eliminate a mental factor.

Twelve of these thought themselves better off under insulin alone, 7, under sodium phosphate alone, and the remainder, under the combination of sodium phosphate and insulin as against insulin alone, stating that they would not be without either.

Conclusions

Sodium phosphate was found to affect favorably the physical and mental status of diabetic patients. In subluxative doses this salt is of undoubted benefit in all forms of fatigue, especially that affecting the skeletal muscles. This salt is a preserver of sugar as proved by its effect on both the blood sugar content and excretion in the urine of 104 diabetic patients and 16 normal patients with low sugar tolerance. It appears to enhance the action of insulin but is in no sense a substitute for the latter, for sodium phosphate does not create extra insulin. A significant

fact is that insulin utilizes phosphates in the conversion of glucose into glycogen

I have given moderate doses of sodium phosphate to over 1,500 patients, including those with diabetes, in the past nineteen years and have never noted any deleterious effect. At least 10 per cent of our patients have taken this salt more or less constantly for over ten years. There is preponderant clinical evidence that sodium phosphate in small repeated doses is productive of increased physical and mental power.

In moderate doses sodium phosphate augments the combining power of CO_2 and conserves the excretion of fluids in almost all true diabetic cases (the diabetic patient is readily dehydrated). On the other hand, because of its mild chologenic action, small doses of sodium phosphate minimize the invariable constipation of these patients.

The administration of sodium phosphate raises the threshold of sugar excretion in the urine and, thus, spares a great deal of anguish to the diabetic patients who are accustomed to test their urine themselves and who become mentally distressed when the color is even only slightly greenish, they then get into real trouble by suddenly limiting their diets to the point of exhaustion and acidosis. Regardless of the extent of the glycemia, sodium phosphate lowers the amount excreted in the urine.

Sodium phosphate is a protection to the ambulatory diabetic patient, who, for some reason or other is unable to follow a strict regimen both as to diet and the use of insulin. It is, however, no substitute for insulin but apparently a good synergist to the hormone and an adjuvant to the general treatment of diabetes.

PSYCHOTHERAPY IN THE GENERAL PRACTITIONER'S OFFICE

"Emotional Factors in the Etiology and Therapy of Medical Conditions" was the subject of a recent address by Louis H. Twyeffort, consulting psychiatrist to the Medical Division of the University Hospital, and psychiatrist to the Pennsylvania Hospital Institute, University of Pennsylvania. He said, in part, that owing to neglect in the past of this phase of therapy in the curriculum of most medical schools, there is a confused idea as to the true etiology of functional disorders, also a completely inadequate comprehension on the part of the patient. There is need to understand the "total person" in treating disease processes. In every illness there is both an anatomic and a mental component, each of which should be properly evaluated.

The majority of functional disorders are primarily psychologically conditioned. It is unfortunate to call them, for instance, "cardiac neuroses," or "gastrointestinal neuroses," as these disorders are actually part manifestations of a larger disorder involving the entire personality. Incapacitating personality traits and attitudes, as well as that which happens to the individual, will cause emotional turmoil and its physiologic repercussion. These traits frequently result, not from inheritance, but from early conditioning by parental attitudes. The overdominant parent may foster overdependency in the child, for example. Such inadequacy will give rise to strong emotions frequently operative on a subconscious level, yet still very active in producing chronic tension states and their physical manifestations.

A comprehensive appreciation of functional illness must remain anatomically oriented. The hypothalamus serves as a bridge between psyche and soma and acts as the chief effector of the emotions by way of the autonomic nervous system. Hence emotional perturbation reflects itself principally in those organs containing

smooth muscle fibers and in disturbance of endocrine glandular tissue.

It is being increasingly suspected that functional disturbances may play a significant role in bringing about actual structural changes and tissue damage. Psychiatric contributions have supplemented our knowledge of the etiology of many cases of peptic ulcer, mucous colitis, etc.

Diagnosis of psychogenesis is established usually in indirect fashion. A thorough personality study should be part of any thorough medical approach to such a case.

No surgery should ever be undertaken "in the hope of relieving" some functional disorder without a complete preliminary psychiatric examination and evaluation.

Psychotherapy in the simpler functional disorders is not a prerogative solely of the neuropsychiatrist but should be handled in the general practitioner's office. By promoting understanding of the meaning of his symptoms and the nature of his conflicts, the clinician may gradually show his patient how strong emotions cause physiologic dysfunctions, with the result that his symptoms may soon have an entirely new meaning for him.

During the treatment the energies of repressed emotional conflicts are converted from their somatic channels into psychic channels, permitting a constructive solution of the conflict through the medium of speech and volition. The successfully treated patient speaks less in terms of his symptoms and more in terms of the situations and inner attitudes which cause their appearance. Where it becomes necessary to refer refractive cases for specialized treatment, the physician can help the patient by acquainting him and his family with the reasons for the need of specialized help, as well as by emphasizing the time, effort, and cooperation necessary for successful results.

—Pennsylvania M J, August, 1941

RESIN DERMATITIS FROM NEW PAJAMAS AND NEW SHORTS

ADRIAN G GOULD, M D , ARTHUR B BERRESFORD, M D , and
NORMAN S MOORE, M D , Ithaca, New York

IT IS our intention to amplify, by means of this report, an article¹ published under the title, "An Outbreak of Dermatitis from New Resin Fabric Finishes."

In the several months after the opening of college late in September, 1940, 5 students were seen with severe acute dermatitis, the onset of which followed the wearing of new shorts or pajamas that had not been laundered. The dermatitis appeared in from a few hours to two days after donning the new clothing. In all of the cases there was a period of about twenty-four hours of penile and scrotal irritation followed by a rash on the inner sides of the thighs which soon became quite generalized over the body except on the head.

The penile irritation consisted of an erythematous macular area extending from the meatus down the foreskin to the most dependent part of the latter. Where the tip of the foreskin made contact with the scrotum there was a similar erythematous area. Both regions were slightly inflamed and they burned and itched. During the next twelve to twenty-four hours, edema of the penis and scrotum occurred. Both became immense in size, and the former looked as though a pin puncture would result in the loss of a considerable amount of fluid.

The eruption on the extremities and trunk was maculopapular, and the presence of scratch marks, due to the intense pruritus, resulted somewhat in the appearance of scabies. The interdigital spaces and the shaft of the penis were free of maculopapular lesions, however. The pruritus was almost intolerable before treatment, the patients complained bitterly of their discomfort and, in several cases, frantically scratched to relieve the irritation.

Four of the 5 patients had histories of various types of allergy. One patient while in the infirmary manifested a mild allergic reaction to ephedrine, which had been administered to him.

Treatment

The following measures were found to be efficacious in these cases of resin dermatitis and were almost routinely used in all of the

group. The patients were admitted to the Cornell University Infirmary, the offending clothing was removed and was replaced by pajamas that had been previously worn without the occurrence of skin irritation. A house diet was provided. A histaminase compound (torantil) was given by mouth up to 25 units four times a day. Calcium gluconate was given in 22½-grain doses three times a day. Starch baths were used during the daytime to allay the pruritus, and calamine lotion with phenol was available at night for local application. These measures gave relief in a short time, and the edema and the eruption subsided simultaneously.

One of the men had put on newly purchased shorts and started by automobile to New York City. After he had driven about 100 miles, the irritation of the skin and genitalia became so disagreeable that he sought a physician's advice and treatment. The administration of epinephrine solution and the application of calamine lotion gave temporary relief. The trip was completed, and several days later upon his return to the university he put on a pair of shorts that also had been newly purchased and not laundered. Within a few hours there was an acute exacerbation of the previous eruption which had somewhat subsided but had not completely disappeared. This was the only patient in which epinephrine had been used. The administration of ephedrine to another of the group resulted in marked edema of the eyelids.

In the original article by Schwartz, *et al.*,¹ the suggestion was made that clothing that might contain the resin should be laundered before wearing. One of our patients, after recovery from his dermatitis, laundered the newly purchased pajamas and upon wearing the suit had a return of his dermatitis, although each laundering seemed to remove more and more of the offending material and lessened the amount of resulting dermatitis. He and others in the group finally discarded the garments or returned them to the merchants from whom they had been purchased. Patch tests were not performed because of the liability of securing a negative response after such a severe allergic response and because of the desire to return the undamaged garments to the merchants for a monetary re-

From the Student Health Clinic and Cornell Infirmary
Cornell University

bate The histories of the cases, the similarity of the symptoms and signs in all, the universal response to the outlined therapy, plus the recurrence of the dermatitis in 2 cases upon re-wearing of the new garments seemed sufficient, with Schwartz's report of widely disseminated cases of a similar affection, to warrant the diagnosis of resin dermatitis

We agree with the observation of Schwartz

and his collaborators that white garments may offend in some persons, as well as colored or striped clothing, and that the garments were not the product of one manufacturing company

ROCKEFELLER FOUNDATION MAKES \$75,000 GRANT TO FINANCE THREE-YEAR STUDY OF HEALTH AGENCIES IN UNITED STATES

The National Health Council, which has served for the past two decades as a clearing house for national voluntary organizations promoting better health, is undertaking a comprehensive study of the activities of all private health agencies in the United States under a special grant of \$75,000 from the Rockefeller Foundation, it is announced by Dr Kendall Emerson, president of the Council.

"Great strides have been made in health education during the past twenty or thirty years," said Dr Emerson, "and the American public has come to understand that it is much more economical, as well as far more humane, to prevent disease than to cure it. Communities throughout the country have built up many excellent private health services devoted to the prevention of illness, and we have now reached a point where it seems desirable to appraise this whole field of endeavor in order that our efforts may be even more effective

"The study will take about three years to complete, and the report will answer such broad questions as the following: What are the various types of state and local voluntary health agencies? What fields do they cover? What methods of cooperation with official health agencies have they established? What do they cost to operate? What types of health work lead to the greatest active participation on the part of the citizens?"

Dr Louis I. Dublin, chairman of a special committee of the National Health Council, which has been making plans for this study, said "It is particularly appropriate that the Rockefeller Foundation should finance such an under-

taking, for it was the support of the Foundation which made possible the establishment of the National Health Council in 1921, and since then the Foundation has shown unmistakable interest in various Council activities. We are especially pleased that the Foundation has met our request to grant a leave of absence to its vice-president, Mr Selskar M. Gunn, one of the world's outstanding authorities on public health problems, to direct this study."

Mr Gunn returned to America recently after a long stay abroad as director of the European headquarters of the Rockefeller Foundation in Paris, now closed because of the war. Previously, he had been in charge of the Foundation's program of rural reconstruction in China.

The active members of the National Health Council include the following: American Red Cross, American Public Health Association, American Eugenics Society, American Heart Association, American Social Hygiene Association, American Society for the Control of Cancer, American Society for the Hard of Hearing, Conference of State and Provincial Health Authorities of North America, Maternity Center Association, National Committee of Health Council Executives, National Committee for Mental Hygiene, National Organization for Public Health Nursing, National Society for the Prevention of Blindness, and the National Tuberculosis Association.

There are two associate members—the American Nurses' Association and the Foundation for Positive Health—and there are two advisory members—the United States Children's Bureau and the United States Public Health Service.

YOUR BEST FRIEND WON'T TELL YOU

Some people walk in their sleep at night. Others sleepwalk straight around the clock. The former may get up a little dull in the morning. The latter are dull all day, and even their best friends won't tell them how dull they are. They

are intellectual sleepwalkers who wander haltingly from cradle to grave, their most exciting powers unexercised—*Stringfellow Barr, president of St. John's College, in the magazine Tomorrow*

History of Medicine

[The Session on History of Medicine was created last year, and four papers were read at the Annual Meeting in Buffalo. Two are herewith published, and the other two will appear in a subsequent issue.—EDITOR.]

HELMHOLTZ IN MEDICINE

ELLIOTT B. HAGUE, M.D., Buffalo, New York

IN 1921 scientific societies in this country and abroad celebrated the centenary of the birth of Hermann Ludwig von Helmholtz. Honored during his lifetime for outstanding achievements in the field of physics, it was he, more than any other, who laid the broad foundations of the science of biophysics. His contributions to thermodynamics, hydrodynamics, electrophysiology, acoustics, physiologic optics, and experimental psychology were of exceptional magnitude.

His early inclination would have led him to devote himself entirely to the field of physics. In his maturity he was always associated actively with institutions of higher learning, and his scientific productions were of such great importance to the then rapidly developing field of physiology that he was immediately recognized, and has since been always honored, as one of the principal architects of the basic preclinical sciences. Moreover, in his later years he devoted himself more entirely to the field of pure physics where his discoveries and pronouncements so greatly opened up the channels of modern scientific methods that his contributions to the field of clinical medicine are relatively obscured and forgotten.

The year 1942 will mark the one-hundredth anniversary of Helmholtz' graduation from the Royal Medical and Surgical Institute in Berlin, where he received a medical education gratis with the understanding that after his graduation he was to serve as a surgeon in the Prussian Army. In this inaugural thesis, presented when he was 21 years of age, he demonstrated for the first time the connection between nerve fibers and nerve cells. It was only eight years previously that nerve cells had been discovered in ganglia and, although no connection between nerve corpuscles and nerve fibers had been observed, one of the greatest of Helmholtz' teachers had held it likely that such a connection existed.

This youthful discovery is regarded by physiologists as laying much of the groundwork of neurologic histology. The previous year he had spent the autumn vacation in the Charité Hospital prostrated by typhoid fever. As a medical student he was cared for without charge, and on his recovery he found that his small stipend, barely enough to cover the expenses of his living, had accumulated sufficiently to enable him to purchase a microscope. In his own words: "The instrument was not beautiful, yet I was able to recognize by its means the prolongations of the ganglionic cells in the invertebrata, which I described in my dissertation."

Helmholtz' contributions to medical science came in the years closely following his graduation in medicine. As I shall briefly list them, I think that the breadth and depth of their medical relevance may surprise you.

For the purposes of this paper it would seem more pertinent to limit biographic data elsewhere available and to touch upon a few unconnected medical topics, illuminated directly or indirectly by Helmholtz' work and comment. Except for his brief army experience, Helmholtz never practiced medicine. He was always reticent in regard to his experience with army discipline, although we do know that he regarded self-discipline more efficacious than that imposed from without. In his later years, it is known, he resented the fact that civilians were subject to pushing and shoving on the sidewalks of Berlin by the uniformed servants of the state. To us it appears important that official circles quickly recognized his actual worth and that he was relieved of the necessity of wasting his mental substance in medical routine.

Perhaps the only real justification for a paper on this subject lies in the need we have today for the same clear thinking that illuminates Helmholtz' method. In the period of his youth, many medical dogmas, long held unquestionable, were beginning to be doubted. As he put it: "It was a period of fermenta-

tion, of the fight between learned tradition and the new spirit of natural science, which would have no more of tradition, but wished to depend upon individual experience" Doubt of the older dogmas as they affected medical treatment led naturally to the position of therapeutic nihilism, and we have had little more to offer our patients, until observations in the new natural sciences have accumulated and, today, are giving medical progress most of its momentum

In his popular writings, Helmholtz frequently recurred to the influence that dogma and deductive thinking played in current medical practice, as well as in the sciences allied to medicine, in his earlier years. Medical deductions based on faulty assumptions were, he was aware, the fundamental error of former medical times. It was, indeed, heresy to carry out original observations either in the laboratory, where investigative work was deemed beneath the dignity of the titled pedagogue, or in the sick room, where it was not considered good form to perform oscultation or percussion or to use a sphygmomanometer or the ophthalmoscope. In his time, medical knowledge based upon authority alone, tinged with a psychologic anthropomorphism, was not easily dislodged, and Helmholtz, possibly better than any other man of his time, popularized the need for widespread medical research and, by so doing, gave it impetus

It is today a curious fact that legislative bodies feel called upon to distinguish between scientific medicine based only upon careful observation of many facts and certain varieties of cult medicine. What Helmholtz said of cult medicine is probably as true today as when he said it in 1877. He pointed out that medical cults assume that it is possible to refer all diseases to a single explanation. "One characteristic of the schools which built up a system on such hypotheses, which they assumed as dogmas, is the tolerance of expression which I have already partially mentioned. One who works upon a well-ascertained foundation may readily admit an error. He loses by so doing nothing more than that in which he erred. If, however, the starting point has been placed upon an hypothesis, which either appears clouded by authority, or is only chosen because it agrees with that which is wished to be believed true, any crack may then hopelessly destroy the whole fabric of conviction."

Although Helmholtz expressed a consistent and calm optimism in regard to medical

progress, this man, who was at once one of the greatest of our medical geniuses and at the same time a keen observer and analyst of social tendencies, realized that eternal vigilance is a real duty if the status of medical practice is to be maintained. "But do not think, gentlemen, that the struggle is at an end. As long as there are people of such astounding conceit as to imagine that they can effect, by a few clever strokes, that which man can otherwise only hope to achieve by toilsome labor, hypotheses will be stated which, propounded as dogmas, at once promise to solve all riddles. And as long as there are people who believe implicitly in that which they wish to be true, so long will the hypotheses of the former find credence. Both classes will certainly not die out, and to the latter the majority will always belong."

In his later years, Helmholtz was singularly distinguished by numerous honors bestowed upon him by institutions of higher learning and by the state of which he was always a loyal citizen, loyal enough, it may be said, to recognize certain superior qualities more inherent in other races than in his own, while at the same time he staunchly maintained the existence of certain fine qualities common in his own countrymen.

We may doubt that under any circumstances his inclination would have led him to develop in himself the qualities that enable the physician to apply the healing arts, and yet it is as one of us that he spoke when he said "I am glad that I am able to address an assembly consisting almost entirely of medical men. Medicine was the intellectual home in which I grew up, and even the emigrant best understands, and is best understood by, his native land." I consider the study of medicine to have been the training which preached more impressively and more convincingly than any other could have done, the everlasting principles of scientific work, principles which are so simple and yet so easily forgotten, so clear, and yet, always hidden by a deceptive veil."

In view of the importance and amplitude of the scientific productions of Hermann von Helmholtz, it is, perhaps, surprising that so little is known of the life and more intimate personal qualities of the man. Although there are several biographies and although some of his students are living today, there is a certain paucity of material that relates well as biography. It appears to have been on this account that one of his biographers, the Scotch physiologist, McKendrick, limits himself

History of Medicine

[The Session on History of Medicine was created last year, and four papers were read at the Annual Meeting in Buffalo. Two are herewith published, and the other two will appear in a subsequent issue.—EDITOR.]

HELMHOLTZ IN MEDICINE

ELLIOTT B. HAGUE, M.D., Buffalo, New York

IN 1921 scientific societies in this country and abroad celebrated the centenary of the birth of Hermann Ludwig von Helmholtz. Honored during his lifetime for outstanding achievements in the field of physics, it was he, more than any other, who laid the broad foundations of the science of biophysics. His contributions to thermodynamics, hydrodynamics, electrophysiology, acoustics, physiologic optics, and experimental psychology were of exceptional magnitude.

His early inclination would have led him to devote himself entirely to the field of physics. In his maturity he was always associated actively with institutions of higher learning, and his scientific productions were of such great importance to the then rapidly developing field of physiology that he was immediately recognized, and has since been always honored, as one of the principal architects of the basic preclinical sciences. Moreover, in his later years he devoted himself more entirely to the field of pure physics where his discoveries and pronouncements so greatly opened up the channels of modern scientific methods that his contributions to the field of clinical medicine are relatively obscured and forgotten.

The year 1942 will mark the one-hundredth anniversary of Helmholtz' graduation from the Royal Medical and Surgical Institute in Berlin, where he received a medical education gratis with the understanding that after his graduation he was to serve as a surgeon in the Prussian Army. In this inaugural thesis, presented when he was 21 years of age, he demonstrated for the first time the connection between nerve fibers and nerve cells. It was only eight years previously that nerve cells had been discovered in ganglia and, although no connection between nerve corpuscles and nerve fibers had been observed, one of the greatest of Helmholtz' teachers had held it likely that such a connection existed.

This youthful discovery is regarded by physiologists as laying much of the groundwork of neurologic histology. The previous year he had spent the autumn vacation in the Charité Hospital prostrated by typhoid fever. As a medical student he was cared for without charge, and on his recovery he found that his small stipend, barely enough to cover the expenses of his living, had accumulated sufficiently to enable him to purchase a microscope. In his own words "The instrument was not beautiful, yet I was able to recognize by its means the prolongations of the ganglionic cells in the invertebrata, which I described in my dissertation."

Helmholtz' contributions to medical science came in the years closely following his graduation in medicine. As I shall briefly list them, I think that the breadth and depth of their medical relevance may surprise you.

For the purposes of this paper it would seem more pertinent to limit biographic data elsewhere available and to touch upon a few unconnected medical topics, illuminated directly or indirectly by Helmholtz' work and comment. Except for his brief army experience, Helmholtz never practiced medicine. He was always reticent in regard to his experience with army discipline, although we do know that he regarded self-discipline more efficacious than that imposed from without. In his later years, it is known, he resented the fact that civilians were subject to pushing and shoving on the sidewalks of Berlin by the uniformed servants of the state. To us it appears important that official circles quickly recognized his actual worth and that he was relieved of the necessity of wasting his mental substance in medical routine.

Perhaps the only real justification for a paper on this subject lies in the need we have today for the same clear thinking that illuminates Helmholtz' method. In the period of his youth, many medical dogmas, long held unquestionable, were beginning to be doubted. As he put it: "It was a period of fermenta-

writings Among his achievements the following are to our interest discovery of the way to measure the angle of aperture in a microscope, leading to important improvement of that instrument, contributions to the analyses and interpretations of heart sounds, a clear clinical description of hay fever—from which he himself suffered—reporting organisms, believed to be pollen granules, which he found in the nasal mucosa, the classical analysis of the action of the muscles of the upper arm. He also founded the science of acoustics and gave the definitive anatomic description of the inner ear

The broad foundations of the field of ophthalmology as we know it today were laid by three men Bowman, of England, whose various anatomic discoveries bear his name, Donders, of Holland, and the German, von Graefe, who from the date of their first meeting in 1851 were in frequent correspondence with one another—"a constant source of stimulus and encouragement, each to the other two" The year of their first meeting was the year that Helmholtz announced his invention of the ophthalmoscope This instrument was received with enthusiasm by von Graefe and by the other leaders in the field of ophthalmology As we know, with it, observation of the interior of the eyeball was made clinically possible for the first time Through the ophthalmoscope the physician was able to observe multiform manifestations of ocular disease and, beyond that, by visualizing changes in the retinal tissues he may contribute to the diagnosis and prognosis of many systemic diseases The ophthalmoscope helps to maintain the close association between the oculist and the internist, an association that we prize partly on account of historical considerations Bowman in his time and, in our time, Sir Henry Smith, to whom more than any other we owe our growing esteem of the intracapsular method of cataract extraction, practiced general, as well as ophthalmic, surgery The triumvirate of Bowman, Donders, and von Graefe, all men of medicine, led us to our present understanding and treatment of the relief of eyestrain

In the invention of the ophthalmometer Helmholtz gave us an instrument that led us to a proper understanding of the cause of astigmatism and enriched our diagnostic armamentarium Among his other ocular

contributions were original and important studies on ocular movements, an interpretation of ocular accommodation, work of primary importance on color sensation and color blindness, and the use of oblique illumination for clinical purposes in his invention

Indeed, so greatly and in so many ways did he contribute to medicine that we are apt to forget or to minimize how much we now depend upon a number of his discoveries

One of the personal characteristics of Helmholtz was modesty He took less pride in his invention of the ophthalmoscope than in his development of brilliant pupils Although he considered it his democratic duty to indicate to the general public the bearing that the new science had on their way of life and, although his public addresses—such as "On Thought in Medicine," "Academic Freedom in the German Universities," and "On the Origin of a Planetary System"—are models of clarity of exposition, he was not popular as a classroom teacher because of the supposed obscurity of his style and the difficulty of following his mathematic explanations

It was on this account that for some time some physicians refused to use the ophthalmoscope, believing that an understanding of his mathematic explanation of the construction of the instrument must precede its clinical use Helmholtz used higher mathematics as the simplest method precisely to express definite relationships and, along with Riemann, preceded Einstein in quite a complete development of the concept of the fourth dimension

Among his pupils were Hertz, the inventor of the hertzian wave used in wireless telegraphy and radio transmission, Stenway, whose instruments won prizes for their mechanical and acoustic excellence, the American psychologist, G Stanley Hall, and the internationally known ophthalmologist, Casey Wood Hermann Knapp knew him, and Dr Nicholas Murray Butler attended his lectures to observe his teaching methods

One must agree with G Stanley Hall that no brief sketch can do justice to a man whose attainments added so greatly to the sum of scientific medical knowledge To the medical historian, the intellectual stature and scientific discretion of Helmholtz are indeed remarkable

454 Franklin Street

largely to a chronologic account of Helmholtz' scientific inquiries. In preface he writes "Helmholtz was one whose private life was known only to a few, and he would have instinctively recoiled from biographical revelations of a purely personal character. At the same time, I have endeavored to give the reader some idea of the man—calm, placid, reserved, thoughtful—whose love of truth, yearning of the spirit of inquiry, and great intellectual powers give him a place in the front ranks of the interpreters of Nature. A life full of intellectual activity, creative, ever productive, could not contain much in the way of trivial accident."

In a biography of Hermann von Helmholtz, Hermann Knapp wrote "The father of Hermann Ludwig von Helmholtz was born in 1792 in Berlin. He chose philology for his support, participated as voluntary chasseur in the campaign against Napoleon in 1813 and 1814, entered the philosophical faculty in Berlin University in 1815, and was called as a teacher to the (Lyceum) in Potsdam, where he received the appointment as professor in 1828. In October, 1820, he married Caroline Penn, the twenty-three-year-old daughter of a Hanoverian artillery officer, a direct descendant of William Penn, the founder of the State of Pennsylvania. Caroline Penn Helmholtz, whose maternal grandmother came of a family of French refugees, was remembered as 'a plain, intelligent and refined woman.' Her speech was direct, her judgment clear, with a kind of divination, apparently without premeditation, she quickly penetrated difficult problems to their remotest consequences, and expressed her opinion in the simplest form."

Hermann von Helmholtz, the eldest of 5 children, was born in Potsdam on August 21, 1821. Frequently ill for the first seven years of his life, he was not considered a precocious child, although his father—a teacher in philology, philosophy, and mathematics—tutored him until he was well enough to attend school. Distinct in his recollections of these earlier years was his inability to remember facts or phrases unless they were organized or related in logical sequences of thought. He always found it impossible to commit prose passages to memory, he found it difficult to remember idiomatic expressions and irregular grammatic forms, this lack of memory for disconnected facts showed itself even in the difficulty of distinguishing between left and right. It is surely noteworthy that a man who correlated and interpreted data dealing with the most fundamental factors of our existence

was able to cope with his environment only as he correlated—only as he interpreted and rationalized.

The year following his graduation in medicine he was a military physician at Potsdam. In 1848 he taught anatomy in Berlin. This teaching appointment followed his announcement of mathematic proof of the doctrine of conservation of energy. When he first informally shared the details of this demonstration with several of his contemporaries, the magnitude of his findings was immediately recognized. DuBois Reymond, widely known in the field of electrophysiology and a former schoolmate of Helmholtz and, with him, one of the cofounders of the Berlin Physical Society, immediately acclaimed this paper as an historical document. When Helmholtz later read it before the Berlin Physical Society he made the occasion the most memorable in the Society's annals, and "manifested himself forthwith as a physicomathematician capable of solving any problem." This paper, which "showed his capacity as a mathematical physicist," furnished the foundation upon which our present sciences of physics and chemistry rest, namely "that all modes of energy are capable of transformation from one to the other but are indestructible and impossible of creation. This had actually been demonstrated for physiological processes by the Heilbronn physician, Robert Mayer, whose priority in this regard Helmholtz recognized, and, for physical phenomena by Joule." but Helmholtz gave it universal application. In 1849 he was made professor of physiology and pathology at Konigsberg. In 1855 he was called to the chair of anatomy and physiology at Bonn and, in 1858, to that of physiology at Heidelberg. His official connection with the teaching of the vital sciences terminated in 1871 when he became professor of physics in the University of Berlin, in 1877 when the Physico-Technical Institute was founded at Charlottenberg, largely at his own recommendation and advice Helmholtz was chosen as its first director. In 1891 the seventieth anniversary of his birth was celebrated in Berlin with great ceremony, in which representatives of all parts of the German Empire and from many countries participated. By the Emperor he was pronounced "Germany's foremost citizen, No. 1 public friend."

It would greatly exceed the limits of this sketch to indicate in detail the scope of Helmholtz' work in the various fields of science or even in medicine. You will find thirty items alone in a bibliography of his ophthalmologic

a medical journal. He also spent a portion of his time in Montreal where his father and brother were then practicing. In 1858 he left Plattsburg for good and set up practice in Montreal. He spent the rest of his life there and contributed many articles to the *British-American Journal*. He died at the early age of 42 on December 19, 1863.

The *Lancet*

In April, 1850, Horace Nelson published the first number of his medical journal. It was called the *Northern Lancet and Gazette of Legal Medicine* and bore on its masthead the motto "Truth Without Fear." The place of publication was Plattsburg. Nelson published this journal continuously for the next six years, but its name and form were changed from time to time.

In July, 1851, one number of a weekly supplement, *American Lancet*, was published. There were no other numbers. Publication of two medical journals was too impossible a task for a man as active as Dr. Nelson. This was also the year in which the St. Lawrence School of Medicine was founded.

In October, 1851, the name was changed to *Nelson's Northern Lancet and American Journal of Medical Jurisprudence*. In April, 1853, it was changed again, this time to *Nelson's American Lancet, A Monthly Journal of Practical Medicine*. The space devoted to legal medicine had been getting smaller and smaller, and this department was finally dropped. In December, 1855, the *Lancet* was changed from a monthly to a weekly publication. This was not an improvement. The quality of its articles and the number of subscribers speedily declined. The last number was published on June 2, 1856.

At the height of its career, the *Lancet* had an exceedingly wide circulation. Letters from readers would indicate that it circulated in at least twenty states—from Vermont down to Georgia in the east and as far west as Wisconsin and Louisiana. However, as new journals serving these areas sprang up, these readers gradually dropped out. In the last feeble year of its life, the *Lancet's* circulation was practically confined to New York and Vermont.

Prior to 1855 the *Lancet* was quite an impressive journal. Its mainstays were the reports of lectures delivered in the various large medical schools. Two series of such reports deserve special mention.

Alfred Nelson, Horace's brother, was a student in the University of London. From

him Horace obtained notes of Professor Anthony Todd Thomson's lectures on medical jurisprudence. These notes were well edited and occupied fully half of each issue of the *Lancet*. They constituted its only claim to being a journal of legal medicine. When Alfred returned to Montreal in 1853, jurisprudence was dropped from the title page.

An even greater attraction were the reports of "Clinical Lectures on Diseases of Women and Children" by Dr. Gunning S. Bedford of New York University. These were reported to the *Lancet* by various medical students. They were not well edited and varied, depending on the reporter, from short, sketchy abstracts to flowery rewritings of the students' notes. These lectures appeared in almost every issue of the journal until 1855, when Dr. Bedford published a book on the subject. This marks the beginning of the *Lancet's* decline.

In addition to these lectures, the *Lancet* contained occasional articles by other authors and numerous articles by the several doctors of the Nelson family. The rest of its pages were taken up with letters from readers, abstracts from other journals, editorials, and whatever miscellaneous matter Dr. Nelson chose to throw in.

Some of this miscellaneous matter seems singularly out of place in a medical journal. For example, "Coffee is largely adulterated with corn, peas, potato-flour and rye, chestnuts, acorns, etc., and to give it a high and rich color sugar is burnt with these substances. Purchase the raw coffee, burn and prepare it, and you will avoid the imposition."

There is neither time nor space enough in this paper to detail the medical and scientific matter that the *Lancet* contained. It was no different from the common medical knowledge of the period which has been amply presented by other writers. One item, however, a reprint from the *London Lancet* of March, 1851, is worthy of note. It is as follows:

"The formation of cancerous growths will be retarded by the application of cold and, were it at all possible to bring down the temperature of an entire growth below the vegetating point, it would inevitably be killed. Apply $\frac{1}{2}$ pound of broken ice, with $\frac{1}{4}$ pound of common salt, keeping it on for five minutes. The skin becomes white in a few seconds. The sore on the breast becomes clean and even healthy in appearance."

Last year the refrigeration treatment of cancer was reintroduced. Yet, it was prac-

HORACE NELSON AND HIS *LANCET*

LEONARD J SCHIFF, M D , Plattsburg, New York

THIS is the story of an obscure man who practiced medicine in a small town in northern New York one hundred years ago. He published a medical journal which, after six years of vicissitude, died. He started a medical school which did not last two sessions. His name is known now but to a few, his journal to a still smaller number, and his abortive medical school only to one or two. Yet, in his lifetime, his voice rang loud and clear and his journal was known from Vermont to Ohio. He was a member of a large and active family of doctors, men who were not only doctors but great political figures.

This man's story has never been told. It is worth telling, for it is an interesting tale. But more than that it is a graphic picture of medicine one hundred years ago.

The Man

Horace Nelson was born in Canada in 1821. The family was distantly related to the famous admiral. Horace's father, Wolfred Nelson, and his uncle, Robert Nelson, were both doctors and apparently good ones. However, they were much more interested in politics than medicine, they were revolutionists and French-Canadian sympathizers in the unsuccessful revolution of 1837. As a matter of fact, Wolfred actually took part in the fighting. His forces were speedily overcome and, following his arrest, he was sent to Bermuda. In 1838 he was allowed to come to the United States and in 1845, following the general amnesty, returned to Canada. He again took up politics and eventually became mayor of Montreal.

Horace was also arrested in 1837 but was allowed to come to the United States. Evidence would indicate that the family settled in Plattsburg, New York, which is about 20 miles from the Canadian border. A great many of the French-Canadian families now living in Plattsburg first came over here at that time.

Horace was 16 at the time of emigration. Nothing is known about the next six years of his life. In 1843 he graduated from the University of New York Medical College and presumably returned to Plattsburg to practice.

It is quite evident from his writings that at least part of his time for the next fifteen years was spent practicing medicine in Plattsburg. It is also quite evident that he was not in this city all of the time.

From 1845 to 1847 he was professor of anatomy and physiology in L'École de Médecine et de Chirurgie of Montreal. This school, after many ups and downs, eventually became incorporated into the University of Montreal Medical College. In 1851, he helped to found the St Lawrence School of Medicine—also in Montreal—and occupied the chair of anatomy. This school lasted only one or two years. Dr Nelson's connection with it was even shorter, for early in 1852 he refers to himself as late professor of anatomy, etc.

Undaunted, however, he joined the faculty of the University of Vermont Medical School in 1853 as professor of theory and practice of medicine and pathology. He occupied this post until 1854, at which time he became professor of surgery and surgical jurisprudence. In 1855 this versatile teacher found it necessary to withdraw from the faculty because of "numerous professional engagements."

Such a varied multitude of teaching positions might be enough to satiate the average man, but Horace Nelson was not an average man. The desire to teach and to spread medical knowledge must have been strong in him. In June, 1854, the New York School of Practical Medicine at Plattsburg, New York, was opened. The professors were Dr Edward Kane, of Plattsburg, Professor Henry Erni, of Vermont, and Dr Horace Nelson, of Plattsburg. There is no doubt that the latter was the principal instigator and moving spirit behind the school. Unfortunately, after one session, the school disappeared. Its life was so brief that it is not even mentioned in the various histories of Plattsburg which deal with this period.

This ended Dr Nelson's teaching. In August, 1854, he was offered a post in the newly organized Atlanta (Georgia) Medical College which he refused. Not even Horace Nelson could commute between Atlanta and Plattsburg and publish a medical journal at the same time.

During all this time Dr Nelson was practicing medicine in Plattsburg and publishing

Case Report

REPORT OF A CASE OF PNEUMOCOCCUS TYPE XVIII MENINGITIS COMPLICATED BY SO-CALLED "SILENT MASTOID"

JAMES M. DOBBINS, M.D., F.A.A.P., and MICHAEL A. BRESCIA, M.D., Long Island City,
Queens, New York

IT WAS thought pertinent to report this case of *Pneumococcus* type XVIII meningitis because it presents some interesting features regarding the course of the disease which lend themselves to speculation concerning additional procedures that may have been followed. This case of pneumococcal meningitis was treated extensively with sulfapyridine and specific serum.

Case Report

J. L. B., a boy, aged 8 months, had *Pneumococcus* type XVIII meningitis.

Past and Family History—The child was born spontaneously at full term, he was an only child and his parents were living and well. He had never been ill and was well until the onset of the present illness on July 13, 1940.

Present Illness—At about 8:00 A.M. on July 13 the parents noted that the child had a temperature, was breathing rapidly, and was less playful than usual. At about noon of the following day the child began to have convulsions involving mainly the right side, and soon the convulsions became generalized, at which time the child was hospitalized.

Physical Examination on Admission—The child was well nourished and well developed and appeared acutely ill and pale. The respirations were rapid. The hands, arms, and legs moved continuously in an uncoordinated manner. There was slight opisthotonos and the neck was somewhat rigid. The abdomen was soft, with no palpable masses, the skin, clear, the throat, reddened. The pupils reacted to light sluggishly. Coarse moist rales could be heard at the right base of the chest. Both eardrums were injected and Kernig's signs were negative, the neck, Brudzinski was positive and the Babinski, doubtful. The patellar reflexes were active. The impression on admission was (1) lobar pneumonia, (2) acute tonsillitis, and (3) bilateral acute catarrhal otitis media.

The following day the child had generalized convulsions with clonic twitchings of the right arm and deviation of the eyes to the right. The neck was more rigid. A spinal tap done at this time revealed cloudily fluid and the culture yielded *Pneumococcus* type XVIII. This same organism was also recovered from the blood.

Treatment (see Chart 1)—The child was on sulfapyridine by mouth for the first eleven days in the hospital and, in addition, received for five days sulfapyridine intrathecally as 2 per cent solution of the sodium salt. At the same time

the child was given specific concentrated anti-pneumococcus rabbit serum* intramuscularly, intrathecally, and one dose intravenously. Sulfathiazole was given for three days when *Staphylococcus hemolyticus* was reported from the right ear culture. In all, the child received 843.5 grains of sulfapyridine (orally 793 grains, intrathecally 30.5 grains, as 2 per cent solution of the sodium salt, and intravenously 15 grains, as 5 per cent solution of the sodium salt) and 180 grains of sulfathiazole (by mouth only). In addition to the sulfonamide compounds, this child received a total of 1,215,000 units of specific concentrated rabbit serum (intramuscularly, 650,000 units, intrathecally, 540,000 units, and intravenously, 25,000 units).

A paracentesis of the right eardrum was performed on July 14 and again on the eighteenth, yielding blood each time. The left ear and mastoid were considered normal by the ear department. A right mastoidectomy was done on July 29. The mastoid appeared to be normal at operation. Culture from pus of the middle ear at operation showed *Pneumococcus* type XVIII. The child received two blood transfusions and other supportive therapy as indicated.

Course—The boy seemed to be improving under the treatment of sulfapyridine and specific serum until July 21 when his condition became critical. He continued to become worse after this date. Difficulty in deglutition was noted, and feeding and medication were given by gavage. A right mastoidectomy was advised because of the downhill course in spite of what appeared to be adequate therapy, but this was opposed because of the precarious condition of the patient and the "lack" of patent clinical evidence of mastoiditis. However, after roentgenologic studies of the mastoids indicated what was thought to be a right mastoiditis, the right mastoid was opened on July 29 and was found to be normal. The operation had no apparent effect on the course of the disease. The condition remained the same notwithstanding all therapy, and the child finally died on August 10, the twenty-ninth day of illness.

In spite of the large doses of the sulfonamide compounds used in this case (an infant of about 15 pounds) there was no vomiting, cyanosis, or other disturbing symptom that could be attributed to the exhibition of the drugs.

Laboratory—The results of blood counts, spinal and blood cultures, and the sulfapyridine determinations of the blood and spinal fluid are noted on Chart 1. The urine findings were negative. The microscopic spinal fluid examinations always revealed large numbers of white blood

Case presented at the Pediatric Staff Conference October 7, 1940.

From the pediatric service of Dr. J. M. Dobbins, St. John's Hospital, attending pediatrician and assistant attending pediatrician, respectively.

*The antipneumococcus serum used was obtained from the Department of Health, City of New York.

ticed (not quite so vigorously) one hundred years ago. To the historian nothing is entirely new.

The nineteenth century was a troublous time for doctors. Suits for malpractice in the case of fractures were apparently common. At any rate, they worried Dr. Nelson enough so that he devised an indemnity bond. In this bond the patient agreed to refrain from suits, actions, and judgments against the physician. If the patient or his legal representative would not sign such a bond, Nelson refused to take the case. He frequently published the bond in the *Lancet* as a warning and example to other physicians.

One of the most interesting features of the *Lancet* is the editorial department. Horace Nelson was a fighter. He carried on a continual editorial battle with doctors all over the country. Most of his opponents were the editors of other medical journals, but he also found time to criticize book reviewers, professors, druggists, lawyers, and many others. Practically every issue of the *Lancet* contains at least one angry or sarcastic editorial. Nelson was not a man who could hold his tongue. On the contrary, he seemed to take a perverse delight in exposing himself to battle. His greatest joy was to take a righteous stand and then fire away—it did not matter whom the bullets hit.

The most lengthy and vicious campaign was directed against David M. Reese, of New York. Reese had once been a minister but had left this profession (Nelson says, he was thrown out). He obtained a medical degree and began to publish a journal, *The New York Medical Gazette*. His particular enemies were the teachers at New York University—especially Dr. Valentine Mott. Now, Nelson was an alumnus of New York University and a former pupil of Mott's. Naturally he sprang to the defense. Reese had some friends who did not agree with Nelson, and so the weary battle dragged itself through all twelve volumes of the *Lancet*.

Another of Dr. Nelson's pet hates was the American Medical Association. Thus, he begins one editorial: "The Association met in St. Louis, on the 2nd day of May, and continued two days in Session. As usual, nothing

of any importance was transacted, and as we can better employ some half dozen pages than by copying the proceedings we will give a short abstract of what was done, leaving our Readers easy to find out what should have been done."

In the last few issues of the *Lancet* the editor describes a case that not only shows his nature but also gives a clue to the character of the period in which he lived. He was called by the coroner to examine the body of a man who had died two months after receiving a head injury. Dr. Nelson asserted that the patient had died not from the injury but because he had been "very unscientifically and injudiciously treated." Not only did he tell the coroner this, he published it in the *Lancet* (naming the doctor whom he accused), and he appeared at the trial as a witness for the man who struck the blow. The prisoner received a sentence of only three years as a result of this testimony. Naturally, this did not increase Nelson's popularity with the medical profession of Plattsburg, and it may be one of the reasons why he left that city, two years later, for Montreal.

Conclusion

This is the story of an active and restless man—a man who had to be always doing something. He was a bold man who took "Truth Without Fear" for his motto and tried to live up to it. But it is more than the story of a man; it is the story of an age in medical history—the nineteenth century.

The nineteenth century was a turbulent, hurly-burly century. It was a period of great vigor and expansion, with all the strife and tribulation that accompany growth. It saw the rise and fall of many medical schools and many journals. It was a time of outspoken acrimonious debate. American medicine was having growing pains.

The story of Horace Nelson and his *Lancet* is, I think, the story of the nineteenth century.

I wish to acknowledge the helpful assistance of Miss Maude E. Nesbit of the New York State Medical Library and Dr. W. W. Francis of the Osler Library, McGill University.

To be merry in the herte is a grete remedie for helth of the body.—*Bishop of Arusiens (1486)*

A college professor has discovered that cockroaches have no vitamin A.

cells with polymorphonucleus predominating. *X-Rays of Mastoids (July 27, 1940)*—X-rays showed a thickening of the sinus plate of the right mastoid with localized rarefaction within the petrous cells. The left mastoid was normal. The findings indicated right mastoiditis.

Autopsy

Brain.—Pia mater and dura were adherent. There was an enormous amount of thick yellow pus present over the entire brain which appeared to be organizing at the base. There was moderate internal hydrocephalus and the ventricles contained cloudy fluid.

Cranial Surfaces.—Both mastoids appeared to be normal, and both lateral sinuses were normal and without thrombi. Removal of the left temporal bone showed the middle and inner ear to be filled with thick yellowish purulent exudate. The ossicular chain was completely surrounded, exudate filling the entire cavity. No evidence of exudate was found in the region of the left internal auditory meatus, there was no localized cerebellar or subdural abscess over the petrous portion of the temporal bone. The mastoid portion of the left temporal bone was necrotic. The right mastoid area was entirely normal.

Anatomic Diagnosis.—(1) Acute suppurative otitis media, left, (2) acute suppurative mastoiditis, left, (3) *Pneumococcus* type XVIII meningitis, and (4) acute parenchymatous degeneration of the liver.

Discussion

One always appears to be the wiser in retrospection rather than in prospect. However, in reviewing this case it appears that the treatment could have been improved by doing a bilateral mastoidectomy at the first relapse despite normal findings by x-rays and the ear department. This child had received what we thought was adequate serum and drug therapy and appeared to be on the way to recovery when there was a sharp turn for the worse and the child became critical. This indicated the presence of a focus that was feeding virulent bacteria into the system, and the most likely site of such a focus must have been either or both mastoids or inner ears. It has been demonstrated that the prognosis in pneumococcal meningitis with a secondary focus is worse than in a so-called primary meningitis¹ and that the sulfonamide compounds are not effective when bone is involved.² One should also bear in mind when dealing with infants that a mastoid can be "silent," i.e., without any apparent clinical manifestations of mastoiditis, that x-ray studies are deceptive, and that with the more recent use of the sulfonamide compounds there have been many reports of

masking of symptoms of mastoiditis, as may have very well occurred in this case.

This case clearly illustrates that greater emphasis should be placed on surgery of mastoids and that these should be explored early despite the lack of either clinical or x-ray evidence of disease when other foci have been eliminated. The futility of the sulfonamide compounds and large doses of type-specific serum to overcome a persistent focus of infection is demonstrated.

No particular reaction in the blood was noted because of the relatively large doses of sulfapyridine and sulfathiazole. However, we noted in this case an antipyretic effect, per se, of sulfapyridine. This has been reported by many.³ After the first series of sulfapyridine (see Chart 1) the temperature came down by rapid lysis, but after the second and third series of sulfapyridine there was a drop in temperature by crisis. The sulfathiazole had no such effect on the temperature.

Judging from the facts and subsequent course in this case, it appears definitely to be clear that surgery of the mastoids must be resorted to early in similar cases even before clinical evidence of mastoiditis is present. This is further confirmed by the lack of benefit from any form of therapy. It is our opinion that closer teamwork by a limited group specializing in the treatment of this disease will offer greater success.

Summary

1 A case of *Pneumococcus* type XVIII meningitis is presented.

2 The advisability of early attack of secondary foci whenever suspected in cases of pneumococcal meningitis is discussed.

3 A fatal result was obtained in spite of the use of large amounts of specific serum and sulfapyridine.

We wish to express our appreciation for the advice and many valuable suggestions given to us by Dr. Josephine B. Neal in the treatment of this case.

apy (6 Gm. daily) the patient expired on the forty-second hospital day

Laboratory Data.—Frequent examinations of the urine were normal. No Bence-Jones protein was found. Stools were negative for occult blood, ova, and parasites, and culture revealed a normal flora. The blood urea nitrogen, uric acid, sugar, chlorides, calcium, and phosphorus were all within the normal limits. Serum cholesterol was 85 mg per hundred cubic centimeters with esters of 45 mg per hundred cubic centimeters. The serum proteins totaled 6.1 Gm per hundred cubic centimeters, but the A/G ratio was inverted, the albumin fraction being 2.9 Gm and the globulin, 3.2 Gm. There was 20 per cent retention of bromsulfalein one hour after the administration of 5 mg per kilogram of body weight. Serologic examination for syphilis was negative. Westergren sedimentation rates varied between 13 and 20 mm per hour. X-ray studies of the long bones, pelvis, and skull were negative. The electrocardiogram and basal metabolic rate were within normal limits. Sputum cultures showed a predominance of *Staphylococcus aureus*, and on one occasion yeast cells were present. Agglutination tests for the enteric fevers, brucellosis, tularemia, and typhus were all negative. Repeated blood cultures showed no growth. Intradermal tests with tuberculin and brucellergin were negative. A Weltmann test showed a band of 5. Hanger's cephalin test was 4 plus. Erythrocyte fragility and heterophilic antibody tests were normal.

Discussion

DR EDWARD F. HARTUNG. In a case of this sort one may select the outstanding finding and then classify the possibilities explaining this particular finding. The leukopenia was an outstanding finding in this patient. There are many causes of leukopenia, but I will mention only a few. Most of them have been ruled out by the thorough laboratory study of this case—typhoid fever, for example. Another possibility is undulant fever, which might give arthralgia or even arthritis. The points against this diagnosis are the negative agglutination tests and the low mortality rate of undulant fever, so I think it would be difficult to defend this as a diagnosis. The virus diseases also cause a leukopenia, but their course is usually of short duration. Toxic drug reactions may result in leukopenia. The medication prescribed for the arthritis in this case may have been the etiologic factor. Pyrimidone, the sulfonamide group, arsenic and

gold medicaments commonly used in the treatment of arthritis may all cause bone marrow changes. An interesting phase of the leukopenia in this case was the drop in the absolute number of both neutrophils and lymphocytes. This feature does not fit in with a diagnosis of agranulocytic angina. Felty's syndrome—consisting of arthritis, splenomegaly, and leukopenia—is another possibility.

Of the above-mentioned causes of leukopenia, there are three that should be considered in the differential diagnosis of this case. These are rheumatoid arthritis followed by (1) toxic hepatitis due to drugs, (2) Felty's syndrome, and (3) undulant fever.

In my opinion the patient had rheumatoid arthritis. She was seen in the dispensary, and it was the impression then that there were some objective signs of arthritis in the joints. The fever, hyperglobulinemia, hypocholesterolemia, and a Weltmann band of 5 favor the presence of an inflammatory process. The relative increase of plasma cells in the bone marrow and the presence of toxic granulation in the neutrophils and the leukopenia indicate a toxic effect on the bone marrow. The patient was treated by her local physician for arthritis, and he may have used arsenic, gold, or one of the sulfonamide group which would result in bone marrow irritation with or without toxic hepatitis.

The abnormal retention of bromsulfalein and the 4 plus Hanger's test suggest liver damage. In arthritic patients who have liver damage with an altered A/G ratio, the sedimentation rate is usually normal. When the sedimentation rate in patients on gold therapy decreases suddenly, we think of a toxic hepatitis.

The absence of splenomegaly makes the diagnosis of Felty's syndrome unlikely. Undulant fever is ruled out by the negative agglutination and intradermal tests.

Dr Hartung's Diagnoses

Rheumatoid arthritis with hepatitis and leukopenia of toxic origin.

Bronchopneumonia, terminal.

DR GREENE. Is there any other discussion before the pathologist gives his report? The impaired bromsulfalein test, the positive Hanger's test, and the hypocholesterolemia indicate liver damage despite the normal icteric index.

DR HERBERT K. ENSWORTH. This patient's chest findings were always more marked on physical examination than the x-ray showed.

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Date May 20, 1941

Presiding Dr Carl H Greene

History

DR ROBERT McGRATH A 42-year-old single woman was admitted to the hospital on December 31, 1940, and died on February 10, 1941. Her family history and past history were negative with the exception of a subtotal thyroidectomy for hyperthyroidism in 1932. The present illness began two and one-half years prior to admission when she noticed stiffness in the joints of the hands and feet. She was treated by her family physician for one month with complete relief. One year later stiffness involving the feet, knees, hips, shoulders, elbows, and hands recurred. There was no swelling or redness of any of these joints. Despite the administration of thyroid extract and a series of injections, some of the finger joints became swollen during this period. At the end of three months she had again completely recovered and remained well for about one year. Three months before admission there was a recurrence of the same symptoms accompanied by moderate pain. She had lost 16 pounds during this period. There was no history of fever.

On admission to the hospital her temperature was 101 F (38.5 C), pulse, 80 per minute, and respirations, 20 per minute. Physical examination showed a well-developed, although somewhat thin woman not appearing acutely ill. The skin was of normal color and texture. Pyorrhea was present, and the tonsils looked chronically infected. The lungs were clear. A soft systolic murmur heard at the apex was not transmitted. Regular sinus rhythm was present, and the blood pressure was 120/80 mm Hg. Active movement of the involved joints was painful, but careful passive movements caused little or no discomfort. Questionable swelling of the wrist and interphalangeal joints was noted. The remaining joints were normal in appearance. An orthopaedic consultant reported limited internal and external rotation of both shoulders. Vascular, neurologic, and gynecologic examinations were normal.

Course in the Hospital—On the day of admission, 10 mg of aurothioglucose was given intramuscularly. On the same day the leukocyte count was 3,600 per cubic millimeter with 87 per cent neutrophils. The red cells numbered 3,850,000 per cubic millimeter, and there were 13 Gm of hemoglobin. A letter subsequently received from her physician stated that two months prior to admission her leukocytes totaled 3,800 per cubic millimeter and the basal metabolic rate was -13. Thyroid extract had been prescribed.

A week after admission the leukocyte count dropped to 1,850 per cubic millimeter with 72 per cent neutrophils. Ten cubic centimeters of pentonucleotide was given intramuscularly, and a severe febrile reaction followed. Daily leukocyte counts ranged between 900 and 2,450 per cubic millimeter, of which 75 per cent were neutrophils and 25 per cent were lymphocytes. Some of the neutrophils showed toxic granulations. Sixteen days after admission a sternal bone marrow biopsy showed a slight increase in the plasma cells. A lymph gland was removed from the left axilla, and normal histologic structure was found on microscopic examination. On the following day, impaired resonance, bronchovesicular breathing, and crepitant rales were noted at the right base associated with herpes labialis. An x-ray of the chest was suggestive of a pneumonic infiltration in the right lower lobe.

From this time on the patient had a febrile course (102 and 103 F) associated with changing pulmonary signs at both bases. Blood pressure readings were consistently low during this period, averaging 88/50 mm Hg. Treatment was symptomatic, consisting of vitamin B complex, yellow bone marrow, liver extract, and a series of blood transfusions. One month after admission an x-ray of the chest showed a possible bronchiectatic lesion in the central portion of the right lower lobe. The patient went rapidly downhill with signs of consolidation at both bases. No pneumococci or tubercle bacilli were found in the sputum. The leukocyte count increased to 5,600 with 90 per cent neutrophils. Despite sulfadiazine ther-

Medical News

County News

Albany County

Dr Edward D Churchill of the Harvard Medical School addressed the county society on October 22 in the Albany College of Pharmacy. His subject was "Wounds of the Chest." The woman's auxiliary met the same night in the auditorium of the Nurses' Home, Albany Hospital. Dr John Swan, of Rochester, was the speaker.

Bronx County

The regular meeting of the society was held at Burnside Manor, 85 West Burnside Avenue, on October 22. Following the executive session, Dr Abner Stern, president, delivered the inaugural address. The research director of the State Health Preparedness Commission, Dr John J Bourke, spoke on "Health Defense and Emergency Medical Service and Their Relation to the General Defense Program in New York State."

The first fall dinner meeting of the Doctors' Club was held at the Park Royal Hotel, West 73rd Street, on November 9, at 7 30 p m.

The Doctors' Club was organized for the cultural and social activities of Bronx doctors. Those interested in joining are requested to communicate with the president, Dr H Silver, or the secretary, Dr H P Posner.

One of a series of Obstetrical Conferences, conducted by the Maternal Welfare Committee and sponsored by the society, will be held on November 19 at 4 00 p m. at the new quarters—District Health Center Auditorium, 1826 Arthur Avenue. The Bulletin announces that doctors wanting reminder cards of the monthly meetings should send their names to the county society offices and they will be put on a special mailing list—a good way to boost attendance.

Canandaigua County

Dr A. W. Armstrong spoke on "Home and Health" before the county society on October 9. Dr Frederick C McClellan was host at Wenna Kenna, with dinner served to 21, Dr J F Maltman presided.

Dr Hubbard K. Meyers, of Buffalo, former president, was among those present. Guests were Dr Hans Hansen and Dr Parker G. Borden, Veterans' Hospital, Dr O J Mason, Farmington, Dr John Marsh, Palmyra, Dr Carl Smith, Victor, Dr Ludwig Mayer, Manchester, and Dr Frederick C Robbins, Brigham Hall.

Dr Margaret T Ross, Brigham Hall, was hostess on November 13.

Dutchess County

At the county society meeting on October 15 a special committee was appointed to consider the question of whether or not the children's preventorium at Bowne Memorial Hospital will be continued.

Dr A. L. Peckham is chairman of the committee and other members are Dr John I

Cotter, Dr E. A. Stoller, Dr Samuel E. Appel, and Dr A. A. Rosenberg.

The report of the committee is scheduled to be given at the society's meeting in November.

A moving picture on "The Vitamin B Complex" was shown, depicting symptoms of deficiency of the vitamin and the effects of treatment.

Dr James T. Harrington, president, presided.

Erne County

At the Fall Clinical Day, held November 13, the guest speakers were Dr Chas. Gordon Heyd, of New York City, former Buffalonian and former president of the American Medical Association, Dr J. C. Meakins, of Montreal, Dr Logan Clendenning, of Kansas City, and Dr Jennings C. Lutzenberg, of Minneapolis.

The evening was devoted to honoring the Buffalo physicians with fifty years or more of practice, who are: Herbert Beals, A. L. Benedict, Alice Bennett, Albert J. Colton, J. Henry Dowd, Sidney A. Dunham, Thomas F. Dwyer, Edgar A. Forsythe, Lawrence George Hanley, Herman E. Hayd, George A. Hummelsbach, Jeannette Hummelsbach, F. Whitehall Hinkel, William Hoddick, John D. Howland, Allen A. Jones, Benjamin G. Long, Eli H. Long, William H. Mansperger, Salo Matheus, Henry John Mulford, Albert W. Persons, Irving W. Potter, Frank B. Rasbach, Anna Reinstein, Charles J. Reynolds, Charles A. Schladermundt, James C. Spiegel, Chester T. Stewart, Emil Tobie, Frank B. Voght, James F. Whitwell, James P. Wilson, and Harry A. Wood.

Doctors in other communities are: William Henry Norrish, Kenmore, Frank Sweetland, Angola, Albert Erb, Clarence Center, E. W. Buffum, East Aurora, Mark N. Brooks and Thomas B. Fowler, Springville, John J. Finerty, Derby, and Edgar J. Foote, Williamsville.

Franklin County

At the county society's annual meeting held in Malone on October 15 the following officers were elected: Dr Frank F. Finney, of Malone, president, Dr Francis Trudeau, of Saranac Lake, vice-president, Dr Daisy Van Dyke, of Malone, secretary-treasurer.

The meeting was held in the Nurses' Home at the Alice Hyde Hospital in the afternoon and was featured by a talk by Dr William H. Wehr of the State Institute for the Study of Malignant Diseases of Buffalo. He told of the newer concepts and developments in operative methods and treatment of cancer.

A dinner at the Hotel Franklin concluded the meeting.

Greene County

At the annual meeting of the county society held in October the following officers were elected:

Dr William V. Wax, of Catskill, president, Dr Elusha B. Van Deusen, vice-president, Dr Wm. M. Rapp, secretary, Dr Mahlon H.

DR MAURICE N. RICHTER I should like to ask whether or not skin lesions were ever noted.

DR McGRATH There was no history of skin eruptions, and none were noted on physical examination.

Pathology

DR RICHTER The gross lesions found at autopsy were not so striking as the clinical features would lead one to expect. In the lungs there were areas of lobular pneumonia and edema. There was thickening of the pleurae, and fluid was present in each pleural cavity. The liver and kidneys were congested. In the heart a small area of thickening was found in the ventricular endocardium beneath the mitral valve. The other organs showed no gross features of interest.

In contrast to the gross findings, the microscopic changes were of great interest, the most important ones being in the heart. Here, there were areas of cellular infiltration in the myocardium between the muscle bundles. The cells appeared to be lymphocytes and mononuclear cells. These cells and cell collections were not the same as in rheumatic fever and were not necessarily related to blood vessels. They formed linear cell arrangements in the interstitial tissues of the myocardium.

In addition to the presence of the cells, there was a change in the appearance of the collagenous fibers. They seemed coarser than usual and slightly more basophilic. With azure-eosin they became differentiated more slowly than normal collagen fibers and were, therefore, more clearly demonstrated.

The only other vascular lesion found was in one of the periadrenal arteries. A small degenerative lesion with cellular infiltration, not unlike the lesion of diffuse vascular diseases such as periarteritis or scleroderma, was noted in one side of the vessel. This lesion was too small to classify accurately.

In the spleen there was a peculiar arrangement of the connective tissue around the arterioles, forming concentric circles of collagen fibers.

Several sections of voluntary muscle were examined, in only one of which a lesion was found. This consisted of a cellular collection in the interstitial tissue too small to study advantageously.

The thyroid gland showed a moderate degree of diffuse hyperplasia with areas of involution. This was compared to sections of the gland removed at operation nine years before and found to be similar.

The lesions described are not comparable to any that I have seen before. Rheumatic fever, interstitial myocarditis of the usual types and periarteritis nodosa can be ruled out. While the case was under discussion in the laboratory, Dr. Arthur C. Allen remarked that the cardiac and splenic lesions were similar to those in cases of lupus erythematosus which he had seen in Dr. Klemperer's laboratory. Accordingly, sections were sent to Dr. Klemperer, who confirmed the diagnosis and permitted us to study some of his material. Dr. Klemperer feels that alteration of the collagenous tissues is the principal underlying change in cases of this type.

The lesions in the heart and spleen are described by Drs. Klemperer, Pollack, and Baehr in a recent paper.

The splenic lesion in particular interested us, since Dr. Homer Kesten recently showed us similar lesions in a spleen removed surgically for purpura hemorrhagica. In his case the patient had had a skin lesion diagnosed as lupus erythematosus thirteen years before.

We have, therefore, made a diagnosis of lupus erythematosus. In this connection it is worth calling attention to the fact that symptoms referable to the joints and reduction in the white cell count, as seen in this case, have been noted in lupus erythematosus before.

Pathologic Diagnoses

Interstitial myocarditis, lupus erythematosus type

Acute arteritis (periadrenal), lupus erythematosus type

Periarterial fibrosis of spleen

Lobular pneumonia, bilateral

Edema of lungs

Hydrothorax, bilateral

Atelectasis, right and left lower lobes

Chronic passive congestion of liver

Hyperplasia of thyroid gland

Montgomery County

A regular meeting of the county society was held on October 14 in Amsterdam at the Elks Club with the president, Dr Julius Schiller, presiding. New members introduced were Dr Leonard Bolognino and his wife, Dr Christine Heffernan, and Dr Daniel P McMahon, district health officer.

The scientific paper was given by Dr J A. Dickson, the subject being "Surgical Indications of Treatment of Peptic Ulcer." The paper was discussed by Dr Welch, professor of surgery in Albany Medical College.

There followed a general discussion participated in by members of the society, after which a buffet luncheon was enjoyed.

The following attended: Dr Julius Schiller, Dr Leonard Bolognino, Dr Christine Heffernan, Dr Welch (Albany), Dr L. H. Finch, Dr Erich Hausner, Dr James P. Curran, Dr William H. Seward, Dr Max Gutmann, Dr E. C. LaPorte, Dr Edwin B. Kelly, Dr Peter J. Lucas, Dr J. A. Dickson, Dr E. J. Collier, Dr C. A. Spence, Dr N. T. Lombardi, Dr G. C. Ferguson, Dr Harry S. Howard, Dr M. T. Woodhead, Dr J. B. Conant, Dr M. F. Geruso, Dr R. R. Violyn, Dr Walter Dreyfuss, Dr John G. Butkus, Dr L. M. McGuigan, Dr S. L. Homrighouse, Dr Adam A. Kindar, and John Zeigler.

Nassau County

Dr Louis H. Bauer has been appointed head of public health and welfare, with Dr A. L. Higgins, deputy head, of the Nassau County Defense Council. Dr Earle Brown, head of the county health department, is the operating head of the health division. A program embracing practically every war emergency health problem has been worked out by the Council with the aid of the County Health Department, the Nassau County Medical Society, and local voluntary organizations.

The plan as set up by the Council will include surveying emergency hospital facilities, ambulance service, nursing service, first aid, sanitation, immunization, the prevention of infection and contagion, and the listing of available medical supplies. Under the supervision of the medical preparedness committees of the county society, a county-wide plan has been worked out under which every physician in the county will be assigned to emergency duty.

New York County

The first meeting of the county society for the fall was held at The New York Academy of Medicine, October 28. Dr Nathan B. Van Etten addressed the meeting on "Triumphs of Optimism in Social and Scientific Medicine, 1841-1941." The Honorable Bernard L. Shientag, Judge, Supreme Court, had as his topic "Whither Medicine?"

One of America's greatest needs, according to Dr Van Etten, is more average practitioners to take care of average patients and fewer medical specialists. He said that most teachers in medical schools are themselves specialists and actually inspire their students to follow their example, with the result that many interns have decided on specialized fields by the time they

begin their internships and seem uninterested in general clinical work. Dr Van Etten advocated the postponement of specialty teaching until it is demanded by the graduate students. He also said that he would like to see many of our specialists re-educated in general medicine in order to improve their appreciation of the importance of coordinated study of the whole patient.

Justice Shientag said that while he did not favor any plan of compulsory health insurance, he believed that the doctors might have to face the likelihood of such a system unless they adequately met the problem of medical costs in serious illness affecting low-income patients.

Dr John C. A. Gerster, for fifteen years chairman of the New York City Cancer Committee, received a testimonial from the American Society for the Control of Cancer at the committee's fifteenth annual dinner held at the Advertising Club in New York City last month. The dinner preceded the opening of the committee's campaign for \$75,000 for its work in 1942. In an address by Dr Frank E. Adair, chairman of the national society's executive committee, he said that the proof of the effectiveness of any such campaign can only be ascertained by exact scientific studies of the facts and that in the case of the New York City Cancer Committee striking demonstration of effectiveness is shown by the fact that in 1920 the operable cases of breast cancer averaged eleven months and seven days between the patient's first noticing a lump and her admission to the hospital for treatment. In 1940 the same type of case averaged only four months and seven days, a reduction of 62 per cent in lost time.

The Doctors' Orchestral Society has resumed its regular weekly rehearsals at the National Hospital for Speech Defects at 61 Irving Place. Mr Fritz Mahler, conductor, directed the National Theatre in Mannheim, conducted the Berlin Radio Symphony, Copenhagen Symphony, British Broadcasting Symphony Orchestra, and other notable symphonies in Stockholm, Budapest, Vienna, Warsaw, and Dresden.

The annual concert will be given at Town Hall, New York City, on May 8, 1942.

Onondaga County

An experiment being conducted in Syracuse by the College of Medicine, Syracuse University, with a grant of the Josiah Macy, Jr., Foundation of New York City, has interested the United States Public Health Service to the extent that Dr Dean A. Clark of the research division spent two days in Syracuse last month looking into the work, which is being carried on by Dr Frode Jensen, extramural resident who maintains offices at University Hospital, in collaboration with Dr Herman G. Weiskotten, dean of the college.

Since July 1, 1940, ward patients of University Hospital, upon being taken to their homes after treatment for medical—not surgical—illnesses, have been given needed treatment by physicians under Dr Jensen's direction.

The purpose of this activity has been to determine whether this practice is the best method of aiding the medical indigent, it has been sought

Atkinson, treasurer. Dr Percy G Waller was named chairman of the legislative committee, Dr T Earl McQuade, chairman of public relations, Dr Kenneth F Bott, Greenville, delegate to the State Society, and Dr William A Petry, alternate.

Herkimer County

Dr Byron G Shults, of Herkimer, was nominated for president of the county society at the meeting held October 14 in the Mohawk Valley Country Club at Herkimer. He has been first vice-president. Other officers nominated were first vice-president, Dr Nicholas D Lill, Dolgeville, second vice-president, Dr Dominick Aloisio, Herkimer, third vice-president, Dr F M Neuendorf, Mohawk, treasurer, Dr A. C Fagan, Herkimer, secretary, Dr Fred C Savin, Little Falls, librarian, Dr George F Eveleth, Little Falls, delegate to State Society meeting in April, Dr George A. Burgin, Little Falls.

Dr Sabin was nominated for his eighth term as secretary and Dr Fagan has completed seven terms as treasurer.

The nominations were proposed by a committee headed by Dr T B O'Neil, of Ilion. Election will take place at the December meeting, but nomination is tantamount to election.

Dr Shults, as first vice-president, presided over this meeting, in the absence of Dr H. Dan Vickers, of Little Falls, president, who is honeymooning in South America.

The medical men discussed the question of fees for county work and the method of payment, but they took no action.

Kings County

The first series of "Lectures to the Laity," sponsored by the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn, in cooperation with the Brooklyn Institute of Arts and Sciences, will be given this winter in the Music Hall of the Brooklyn Academy of Music at 8 15 P.M.

The series includes "Devils, Drugs, and Doctors," Mr Howard W Haggard, professor, Department of Applied Physiology, Yale University, Tuesday, October 28, 1941. "Relation of Medicine to Crime Detection," Dr Thomas A. Gonzales, chief medical examiner, City of New York, Tuesday, November 25, 1941. "What and Why Is Your Mind?" Dr Foster Kennedy, professor of neurology, Cornell University Medical College, Tuesday, January 27, 1942. "The Man Within the Patient," Dr George Draper, associate professor of clinical medicine, Columbia University Medical College, Tuesday, February 24, 1942. "Food, Faith and Civilization," Dr Walter C Alvarez, senior consultant in medicine, Mayo Clinic, Rochester, Minnesota, Tuesday, March 24, 1942.

The regular meeting of the Pediatric Section of the county society will be held on Monday, November 24, at 8 30 P.M. at the County Building, 1313 Bedford Avenue. A paper, "The Foot Problem in Children," will be given by Dr Dudley J Morton, of New York City. Dr Herbert C Fett, of Brooklyn, will discuss the paper.

The profession is cordially invited to this meeting.

The first fall meeting of the county society was held on October 21. The speaker for the scientific session was Dr William P Murphy of Boston. He discussed two subjects, "Chronic Leukemia" and "Esophageal Hiatus Hernia." The latter subject is an unpublished paper of particular interest to hematologists, gastroenterologists, and general practitioners. Dr Murphy is consultant hematologist at the Melrose Hospital, senior associate in medicine at the Peter Bent Brigham Hospital, and associate in medicine at Harvard University.

Madison County

Dr Eugene W Carpenter, Oneida, was named president of the county society at the 135th annual meeting on October 16 in Oneida. He succeeds Dr Howard Beach, Oneida, who presided at the two sessions and dinner of the medicos.

Dr Lee S Preston, Oneida, and Dr Paul Ferrara, Canastota, were renamed secretary and treasurer, respectively. Dr Jackson W Thro, of Hamilton, was selected as vice-president.

Delegates to the annual meeting of the New York State Medical Society are Dr Carpenter and Dr Beach. Dr Otto Pfaff, dean of the Oneida Medical Society, was reappointed to the board of censors. Other members are Dr Robert L. Crockett, Oneida, and Dr O H Langworthy, Hamilton.

Speaking on the medical preparedness in national defense, Dr John J Bourke, research director of the New York State Department of Health, outlined the emergency medical service for the state.

Dr E C Hughes, Syracuse, presented a paper at the evening session on "Relationship of the Thyroid and Adrenal Glands to Toxemias of Pregnancy." Colored slides on "Skin Lesions" were shown and explained by Dr Leon Griggs, Syracuse. Dr Beach gave a paper on "Surgical Gallbladder Cases."

Monroe County

The regular meeting of the county society was held on October 21 at the Academy of Medicine in Rochester.

Dr James K Quigley was nominated to succeed Dr C Stewart Nash as president of the Monroe County Medical Society when it holds its annual meeting in November.

Other men nominated were Dr G Kirby Collier, vice-president, Dr William A MacVay, for re-election as secretary, and Dr John L Norris, treasurer.

Nominations preceded a discussion on food supplies and nutritions in France led by Dr John B Youmans of Vanderbilt University School of Medicine and member of the Rockefeller Health Service Commission to France from December, 1940, to June, 1941.

"To some extent, the French nutritional laws may be of help to this country, if future developments warrant," Dr Youmans declared. He said France was still receiving food from its colonies when he left, but there were too many uncertainties in its development as a conquered country to tell what the future might hold.

Montgomery County

A regular meeting of the county society was held on October 14 in Amsterdam at the Elks Club with the president, Dr Julius Schiller, presiding. New members introduced were Dr Leonard Bolognino and his wife, Dr Christine Heffernan, and Dr Daniel P. McMahon, district health officer.

The scientific paper was given by Dr J. A. Dickson, the subject being "Surgical Indications of Treatment of Peptic Ulcer." The paper was discussed by Dr Welch, professor of surgery in Albany Medical College.

There followed a general discussion participated in by members of the society, after which a buffet luncheon was enjoyed.

The following attended: Dr Julius Schiller, Dr Leonard Bolognino, Dr Christine Heffernan, Dr Welch (Albany), Dr L. H. Finch, Dr Erich Hausner, Dr James P. Curran, Dr William H. Seward, Dr Max Gutmann, Dr E. C. LaPorte, Dr Edwin B. Kelly, Dr Peter J. Lucas, Dr J. A. Dickson, Dr E. J. Collier, Dr C. A. Spence, Dr N. T. Lombardi, Dr G. C. Ferguson, Dr Harry S. Howard, Dr M. T. Woodhead, Dr J. B. Conant, Dr M. F. Geruso, Dr R. R. Violyn, Dr Walter Dreyfuss, Dr John G. Butkus, Dr L. M. McGugan, Dr S. L. Homrighouse, Dr Adam A. Kindar, and John Zeigler.

Nassau County

Dr Louis H. Bauer has been appointed head of public health and welfare, with Dr A. L. Higgins, deputy head, of the Nassau County Defense Council. Dr Earle Brown, head of the county health department is the operating head of the health division. A program embracing practically every war emergency health problem has been worked out by the Council with the aid of the County Health Department, the Nassau County Medical Society, and local voluntary organizations.

The plan as set up by the Council will include surveying emergency hospital facilities, ambulance service, nursing service, first aid, sanitation, immunization, the prevention of infection and contagion, and the listing of available medical supplies. Under the supervision of the medical preparedness committee of the county society, a county-wide plan has been worked out under which every physician in the county will be assigned to emergency duty.

New York County

The first meeting of the county society for the fall was held at The New York Academy of Medicine, October 28. Dr Nathan B. Van Etten addressed the meeting on "Triumphs of Optimism in Social and Scientific Medicine, 1841-1941." The Honorable Bernard L. Shientag, Judge, Supreme Court, had as his topic "Whither Medicine?"

One of America's greatest needs, according to Dr Van Etten, is more average practitioners to take care of average patients and fewer medical specialists. He said that most teachers in medical schools are themselves specialists and naturally inspire their students to follow their example, with the result that many interns have decided on specialized fields by the time they

begin their internships and seem uninterested in general clinical work. Dr Van Etten advocated the postponement of specialty teaching until it is demanded by the graduate students. He also said that he would like to see many of our specialists re-educated in general medicine in order to improve their appreciation of the importance of coordinated study of the whole patient.

Justice Shientag said that while he did not favor any plan of compulsory health insurance, he believed that the doctors might have to face the likelihood of such a system unless they adequately met the problem of medical costs in serious illness affecting low-income patients.

Dr John C. A. Gerster, for fifteen years chairman of the New York City Cancer Committee, received a testimonial from the American Society for the Control of Cancer at the committee's fifteenth annual dinner held at the Advertising Club in New York City last month. The dinner preceded the opening of the committee's campaign for \$75,000 for its work in 1942. In an address by Dr Frank E. Adair, chairman of the national society's executive committee, he said that the proof of the effectiveness of any such campaign can only be ascertained by exact scientific studies of the facts and that in the case of the New York City Cancer Committee striking demonstration of effectiveness is shown by the fact that in 1920 the operable cases of breast cancer averaged eleven months and seven days between the patient's first noticing a lump and her admission to the hospital for treatment. In 1940 the same type of case averaged only four months and seven days, a reduction of 62 per cent in lost time.

The Doctors' Orchestral Society has resumed its regular weekly rehearsals at the National Hospital for Speech Defects at 61 Irving Place. Mr Fritz Mahler, conductor, directed the National Theatre in Mannheim, conducted the Berlin Radio Symphony, Copenhagen Symphony, British Broadcasting Symphony Orchestra, and other notable symphonies in Stockholm, Budapest, Vienna, Warsaw, and Dresden.

The annual concert will be given at Town Hall, New York City, on May 8, 1942.

Onondaga County

An experiment being conducted in Syracuse by the College of Medicine, Syracuse University, with a grant of the Josiah Macy, Jr., Foundation of New York City, has interested the United States Public Health Service to the extent that Dr Dean A. Clark of the research division spent two days in Syracuse last month looking into the work, which is being carried on by Dr Frode Jensen, extramural resident who maintains offices at University Hospital, in collaboration with Dr Herman G. Weiskotten, dean of the college.

Since July 1, 1940, ward patients of University Hospital, upon being taken to their homes after treatment for medical—not surgical—illnesses, have been given needed treatment by physicians under Dr Jensen's direction.

The purpose of this activity has been to determine whether this practice is the best method of aiding the medical indigent, it has been sought

to determine whether both the community and the patient benefit from this procedure

The aid provided by the foundation provides for poor people the after-hospital care that those able to pay for medical service would normally receive at their own expense. The object is to improve the health of the patient and prevent the need of further hospitalization.

The objective of the experiment, according to Dr Weiskotten, is to provide continuity of medical care to save hospitalization, both by returning patients to their homes earlier because of available medical supervision and, by such continued medical supervision, to prevent recurrence of disease and return to the hospital.

The program is being carried out with the full approval of the county society, the Syracuse Academy of Medicine, and the Syracuse and Onondaga County Health departments.

Syracuse psychiatrists will be present at the free dispensary when Selective Service enrollees from Onondaga County are given medical examinations at the city clinic held for military examination. This was decided at a recent meeting of draft board physicians held at the Syracuse State Psychopathic Hospital, with Dr Noble R. Chambers presiding. The meeting was arranged by the Syracuse mental hygiene committee in cooperation with the defense committee of the county society.

Dr Harry A. Steckel, superintendent of the Psychopathic Hospital, told of three men inducted into the army who broke down within three months because of psychopathic conditions previously undetected. Dr Eugene Davidoff said that emotional traits constituting a psychopathic personality made some men unfit for military service. Dr H. B. Lang, of Albany, Col. H. Gaus, Dr Jerome Alderman, Dr Eugene N. Boudreau, Dr F. Ross Haviland, Dr A. B. Siewers, and Dr Edward S. Van Duyn were other speakers.

Ontario County

At the annual meeting of the county society held at Canandaigua on October 14 the following members were elected: president, Dr M. Edgerton Deuel, Geneva, president-elect, Dr Adrian S. Taylor, Clifton Springs, secretary and treasurer, Dr Daniel A. Eiseline, Shortsville, censors, Dr M. W. Gasper, Gorham, Dr P. M. Standish, Canandaigua, and Dr A. M. Stewart, Naples, delegate, Dr Homer J. Knickerbocker, Geneva, and alternate, Dr Melville D. Dickinson, Geneva.

Dr Eiseline was elected for his forty-fifth consecutive term as secretary-treasurer of the county society.

Rensselaer County

At the county society's first meeting of the fall, held at the Hendrick Hudson Hotel in Troy on October 14, Dr Joseph S. Lawrence, of Albany, executive officer of the Medical Society of the State of New York, said that public health from a government standpoint is here to stay but planned and executed by physicians. He said the government desires a widespread health program but is giving individual physicians the opportunity through the county societies to work out the actual setup.

St. Lawrence County

The county society held a meeting on October 14 in Potsdam and elected Dr W. J. Baldwin, of Potsdam, as president to succeed Dr U. R. Plante. Other officers chosen were Dr F. E. Clark, Ogdensburg, vice-president, Dr Robert Reynolds and Dr J. McNulty, both of Potsdam, re-elected secretary and treasurer, and Dr M. J. Stearns, Ogdensburg, Dr Frederick Mason, Massena, and Dr Robert Reynolds, censors.

Schenectady County

Dr William H. Meyer, of Poughkeepsie, director of the Dutchess County Maternal Health Center, spoke to members of the county society on October 16 at the Ellis Hospital in Schenectady in commemoration of the twenty-fifth anniversary of the founding of the first birth control clinic.

Dr Meyer's topic was "Medical and Surgical Aspects of Birth Control." He said he was glad to have an opportunity to endorse the Schenectady Maternal Health Center and the work of the Schenectady Maternal Health League. He spoke of the work of Mrs. Margaret Sanger, who founded the first clinic, and said he was proud to be able to take part in the anniversary celebration. According to Dr Meyer, the local center is playing an important part in community life.

Dr Norman D. Kathan, medical director of the Schenectady Center, led a discussion that followed Dr Meyer's talk.

At the Ellis Hospital in Schenectady on November 13 was held a "teaching day" on clinical medicine and surgery and maternal and child welfare. Following the morning session, which was devoted to surgery, medicine, and the specialties, there was a luncheon in the Nurses' Cafeteria. Dr Charles E. Wiedenman, president of the county society, opened the afternoon session, which dealt with maternal and child welfare. Dr William M. Malia, regional chairman in obstetrics, was chairman of the meeting.

Schoharie County

Dr Roy G. S. Dougall, of Cobleskill, was elected president of the county society at the annual meeting held in Cobleskill on October 16. Other officers are vice-president, Dr Leroy Becker, Cobleskill, secretary, Dr Donald Lyon, Middleburgh, treasurer, Dr Duncan L. Best, Middleburgh, delegate to the State Society meeting, Dr David W. Beard, Cobleskill, censor, Dr Joseph Duell, Jefferson.

Scientific papers were given by Dr John Hesslen, of Albany, Dr Joseph Cornell of Schenectady, and Dr John Lyon, of Albany.

Steuben County

The county society held a meeting following a dinner at the Hotel Wagner in Bath on October 16. The meeting was under the direction of Dr M. J. MacFarland, Hornell, with Dr George Peterson of Post-Graduate Hospital, New York City, as the speaker. Dr Peterson, noted brain surgeon, discussed "Head Injuries." More than 35 attended the meeting.

Suffolk County

The Suffolk County Cancer Committee, assisted by the county society and the County Department of Health, recently mailed its annual fall appeal to 25,000 families in Suffolk County.

Dr Charles C Murphy, of Amityville, chairman, said that as a result of the educational work of the Suffolk County Cancer Committee more cancer patients are now seeking medical advice earlier than ever before.

The work of the committee extends beyond education. X-ray and radium treatments are supplied to cancer patients who cannot afford treatments but who are not on county relief. Transportation for cancer patients to and from the clinics is provided when needed.

Sullivan County

On November 19 at the Lenape Hotel in Liberty, the subject for the lecture, which is one of a series on pediatrics, will be "The New York State Program for the Rehabilitation of Handicapped Children" by Dr Francis Carr.

On November 26 at the home of Dr Harry Golembé, 111 Champlin Avenue, Liberty, the subject will be "Infectious Diseases of Childhood." The speaker, Dr A. C. Silverman, is professor of clinical pediatrics, Syracuse University College of Medicine.

Washington County

At the annual meeting of the county society held in the Court House in Hudson Falls on October 14, Dr Elias W Young, of Cambridge, was elected president to succeed Dr William C Cuthbert, of Hudson Falls.

Dr Arthur E Falkenbury, of Whitehall, was named vice-president, Dr Denver M Vickers, of Cambridge, secretary, and Dr Charles A. Prescott, of Hudson Falls, treasurer.

On the board of censors are Dr Cuthbert, of Hudson Falls, Dr R. E. Borrowman, of Fort Edward, Dr W S Bennett, of Granville, and Dr Charles H Holmes, of Cambridge. Dr Kennedy Creavy, of Cambridge, was named chairman of the committee on legislation. Dr Michael A. Rogers, of Greenwich, was named chairman of the committee on public relations and medical economics. Dr Vickers, of Cambridge, was named delegate to the State Society.

Dr Cuthbert spoke on practical application of short-wave diathermy.

Dr J G Fred Hiss, of Syracuse, professor of clinical medicine, Syracuse University College of Medicine, addressed the physicians on "Rheumatic Fever and Rheumatic Heart Disease."

Westchester County

"The Art of the Practice of Medicine" was the title of an address given before the county society on October 21 by Dr Walter L Niles, professor of medicine at Cornell University Medical School. Dr Niles' talk was heard by more than 200 physicians attending the meeting at New York Hospital, Westchester Division.

Dr Frederick E Elliott, of Brooklyn, secretary of the Medical Expense Fund of New York, outlined the medical expense insurance plan which is now offered by his organization throughout the entire metropolitan area. The Westchester County Medical Society has endorsed this organization's plan of service.

Wyoming County

The fiftieth anniversary of the practice of medicine by Dr Mary T. Greene, of Castile, was celebrated as a part of the program at the monthly meeting of the county society which was held at the Community Hospital on October 15.

TUBERCULOSIS ABSTRACTS

A Review for Physicians

ISSUED MONTHLY BY THE NATIONAL TUBERCULOSIS ASSOCIATION

Vol. XIV

September, 1941

No 9

TEN years ago no more than a dozen school health administrators were actively seeking out tuberculosis among the students in colleges and universities, despite the acknowledged prevalence of the tubercle bacillus for those of this age group. Today, 248 institutions of higher learning have some form of program for the finding of tuberculosis on the campus. The Tenth Annual Report of the Tuberculosis Committee of the American Student Health Association is both a record of progress and a reminder of what is still to be done.

FINDING TUBERCULOSIS AMONG COLLEGE STUDENTS

The colleges and universities of the United States and Canada are becoming increasingly "unfair to tuberculosis!" They are showing that they recognize an obligation to safeguard and improve campus health and the present report of the Tuberculosis Committee relates action such as no previous report has recorded.

For the academic year of 1939 to 1940, 248 colleges had some form of tuberculosis control, an increase of about 50 per cent over the preceding school year. Necessarily, where a movement is gaining new adherents annually, the character of individual programs varies greatly. There are still 629 colleges with no program but about 30 of these hope to initiate one this year. Although 402 schools neglected to return the questionnaire sent by the Committee, there were 193 additional replies this year. In spite of this, six states have failed to report a single collegiate tuberculosis program.

The duties of the Committee fall into three divisions: first, the presentation to interested schools of the most approved outline of workable institutional tuberculosis case-finding, second, the active encouragement of interest in case-finding, and third, the collection, analysis, and publication of statistical data secured from colleges taking part in the national survey.

Since the statistical data collected by the Com-

mittee are submitted by many people and accumulated under widely differing conditions, some are open to criticism, so the report figures are indicative of trends rather than mathematical pronouncements.

The procedure is to mail questionnaires early in May to cooperating schools, and a follow-up is sent in October when necessary. Nothing is asked which would require the keeping of complex records. The form requests the name and enrollment of the college, number of positive reactors to tuberculin, tuberculosis cases discovered and their disposition, and the number of students tuberculin tested and x-rayed elsewhere than on the campus. Similar data are requested on nonstudent tuberculosis. Returns are divided by sex. The reverse side contains questions as to procedure which, in general, can be answered by a check mark. The recommended techniques are plainly underlined. A duplicate copy of the questionnaire is sent for the use of the health officer of the institution.

This year questionnaires were sent to 20 colleges and universities in Canada. There is no Canadian student health association and so frequent have been the requests for information that it was decided to circulate these colleges. Several fine programs are already under way in Canada.

More colleges have discovered this year that a relatively simple system suffices to keep track of tuberculin testing, negative and positive reactors, x-ray results, etc. It is essential that those conducting health work know, at any time, the exact status of their effort and the result.

The Committee agreed that tuberculin testing is a prime prerequisite to a tuberculosis case-finding plan and believes that only thus can all infected students be identified. The Committee recommends the annual retesting of all negative reactors since the initial infection occurring in a young adult may produce an unpredictable clinical sequence of events. Where hazards of infection are heightened, as in nursing, medicine, dentistry, practice teaching, etc., more frequent testing is indicated.

The Committee recommends that only reliable tuberculin be used and that a positive reaction to the tuberculin test be succeeded by a good chest film. Where possible, the fluoroscope should be used as a supplement to the film.

In Table 1 data from 168 colleges are compiled because their figures seemed satisfactory in quality. The continued shrinkage in positive reactors seems to indicate a national decline in childhood infection.

TABLE 1—TUBERCULIN TESTING OF AMERICAN COLLEGE STUDENTS

Year	Total No Tested	Percentage Positive
1932-1933	14 318	35 0
1933-1934	25 184	30 3
1934-1935	26 861	29 4
1935-1936	31,601	30 0
1936-1937	56 224	27 3
1937-1938	64 232	25 8
1938-1939	82 774	25 5
1939-1940*	123 389	25 4

* Reliable returns only

TABLE 2—CASES OF PULMONARY TUBERCULOSIS DIAGNOSED AMONG COLLEGE STUDENTS 1939 TO 1940

	A*	B†
Clinically active cases diagnosed‡	292	21
Apparently arrested cases diagnosed‡	345	14
Withdrawals due to tuberculosis	273	25
Old cases back in school	338	23
Institutions reporting	248	227
Approximate total enrollment	490 000	200 000

* In institutions with some tuberculosis control program.

† In institutions with no tuberculosis control program.

‡ Generally recognized criteria of activity were specified.

Using only the active cases for comparison, it is seen that such cases were turned up with much greater frequency in Group A. It is fair to presume that these cases were found early, often preclinically, instead of late and with marked signs and symptoms, which proves again the importance of early diagnosis.

Educators are sensing the urgency that animates an enlightened citizenry intent on eliminating every preventable disease. The ultimate aim

of the Committee is to report that in answer to their questionnaire, every American college has replied.

"We have a modern tuberculosis control program, and tuberculosis will not catch this college or any of our students napping"—*Tenth Annual Report of the Tuberculosis Committee, American Student Health Association, 1939 to 1940 by Charles E. Lyght, M.D., Chairman Journal-Lancet, April, 1941*

INCREASE OF INSANITY IN THE AGED

There will be a huge increase in mental disease of the aged in America if present trends continue, Dr Oscar Kaplan, University of California psychologist, predicted recently as reported in *California and Western Medicine*.

Dr Kaplan, who has just completed a study of the psychopathology of later life, said that the increase in insanity in America in recent years is due largely to a rise in the number of persons above 45 being admitted to institutions.

He pointed out that in 1937 approximately 49.5 per cent of all first admissions to state hospitals in the United States were more than 45 years of age.

On the basis of present trends the percentage of persons above 65 in the United States will double in the next thirty or forty years, and Dr Kaplan says that this in itself will add greatly to the number of older demented.

Other factors that will lead to an increase in the number of elder mental cases admitted to institutions include:

The increase in population of the United States as a whole means that the absolute number of persons above 45 will be greatly increased.

The improvement in public institutions and resultant rise in public confidence will make relatives more willing to part with troublesome older members of the family.

The trend toward urbanization, although it has been arrested in many places by the development of suburban areas, may make it necessary for families to give elder psychotic patients over to institutions. Urbanization creates problems unknown to simpler society, it is easier to care for seniles on a farm than in a city.

Better diagnosis may result in more commitments.

MEDICINE AND CULTURE

In an address delivered at the opening exercises of Cornell University Medical College, Dr Samuel Z. Levine stressed the social responsibilities of the physician. There is no doubt that our medical schools stand high and that in them the best instruction in the world is now given in various branches of medicine. But more is demanded of a physician than professional knowledge. The whole personality should be developed to exploit the full benefit of a scientific education. We have only to think of William Osler, Oliver Wendell Holmes, Harvey Cushing, and S. Weir Mitchell to grasp the significance of what Dr Levine preached. These were not only outstanding physicians but men of the world, men of culture, men who were leaders not only in their professions but in the community because of their broad human outlook.

More than any other science, medicine is concerned with human relationships. It is well enough to diagnose disease with the aid of the microscope, the stethoscope, and the test tube. Psychic factors are involved that defy the laboratory technician. It is precisely here that men like Holmes, Osler, Cushing, and Mitchell shone. Mind must meet mind at the bedside. In this sense Voltaire and Kant, Spencer and Macaulay have as much to convey to the practitioner as any professor of pathology. And so Dr Levine would establish a course in social medicine in every medical school to inculcate broad humanism as well as a sense of civic obligation. Give us this humanism and doctors will be in no danger of becoming bureaucrats under some system of "socialized" medicine that would compel them to treat their patients as living machines rather than as thinking human beings.

—*Editorial, New York Times, September 11, 1941*

NO RETREAT, NO SURRENDER!

"The medical profession now represents the only important group in the United States which, while harassed from within and without, has shown no slightest signs of capitulation."

"On the basis of this fact, it has automatically placed itself in the position of an intellectual leadership of those individuals, groups, and institutions which seek to preserve the important elements of individual freedom and initiative and the principle of 'Free Enterprise'."

"If we live up to this opportunity and the serious responsibility it entails, the physicians of this country can—while preserving the independence of American Medicine—most importantly and vitally serve their country during its period of crisis and greatest stress."

—*Dr Edward H. Cary, president, National Physician's Committee for Extension of Medical Science*

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Privilege—Public Health Records

THE Court of Appeals has recently handed down a decision of considerable importance, passing upon the extent to which certain records compiled by reason of the provisions of the Public Health Law are privileged.*

Section 25 of the Public Health Law prescribes various procedures to be followed for the prevention of the spread of infectious, contagious, or communicable diseases and, among other things, directs that physicians shall report every case of such disease to the State Department of Health and to the Health Officer of the county seat, town, or village where the disease occurs. The State Sanitary Code has included a direction that information concerning known or suspected typhoid carriers should come within the provisions of the law. Said Section 25 contains the following language: "Reports of cases of tuberculosis, syphilis, chancre, and gonorrhea, including laboratory reports, shall not be divulged or made public so as to disclose the identity of the persons to whom they relate, by any person, except insofar as may be authorized by the public health council." It should be noted that the statute is not specific as to whether information concerning typhoid carriers could properly be divulged or whether such cases would be in the same category as cases of tuberculosis and venereal disease.

The section of the Civil Practice Act which deals with professional information generally, so as to prevent its disclosure in many situations, is Section 352 of the Civil Practice Act, providing as follows:

"A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, unless, where the patient is a child under the age of 16, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto upon any examination, trial, or other proceeding in which the commission of such crime is a subject of inquiry."

Plaintiff, in the case referred to, instituted an action as administrator of the estate of a deceased person against the defendant, in which the claim was that defendant in her hotel had, being a known typhoid carrier, prepared and handled food served to the decedent. The action sought damages for the death of decedent from typhoid fever, the claim being that the fatal bacillus was transmitted by the food handler. In the course of the case the plaintiff made an application before the Court at Special Term giving notice, both to the County Health

Commissioner and the State Department of Health, to obtain an order directing each to produce upon the trial of the action all records that might indicate that the person in question was in fact a typhoid carrier. Upon the argument of the application the Attorney General and the County Health Commissioner were not in agreement as to whether they should oppose the application as an invasion of the privilege forbidding the disclosure of confidential communications. The motion was granted and the Court made an order for the issuance of a subpoena directing the production of the records in court. The County Health Commissioner appealed to the Appellate Division and that Court reversed the order.

The plaintiff took the matter to the Court of Appeals, where the order of the Appellate Division was reversed and that of the Special Term affirmed, the ruling being that under all the circumstances present, the records were not privileged and should be produced in court. In the course of its opinion, the Court of Appeals stated:

"We decide, however, that no privilege attaches to these records and that the public policy of the State, as expressed in the Public Health Law (Cons. Laws, chap. 45) and the State Sanitary Code, confers no such privilege. Privilege does not exist unless conferred by some statute (*People vs. Austin*, 199 N. Y., 446, 451). Here the statutes point the other way and seem to require that such records, insofar as they refer to known or suspected typhoid carriers, be made available in a case like this. The Sanitary Code, which has the force of law (Public Health Law, Sec. 2-b), requires local health officers to keep the State Department of Health informed of the names, ages, and addresses of known or suspected typhoid carriers, to furnish to the State Health Department necessary specimens for laboratory examination in such cases, to inform the carrier and members of his household of the situation, and to exercise certain controls over the activities of the carriers, including a prohibition against any handling by the carrier of food which is to be consumed by persons other than members of his own household (see Sanitary Code, chap. 2, regulations 1, 13, 31, 32, 33, and 34). Why should the record of compliance by the county health officer with these salutary requirements be kept confidential? Hidden in the files of the health office it serves no public purpose except a bare statistical one. Made available to those with a legitimate ground for inquiry, it is effective to check the spread of the dread disease. It would be worse than useless to keep secret an order by a public officer that a certain typhoid carrier must not handle foods which are to be served to the public.

* *Thomas vs. Morris*, N. Y., Court of Appeals, July 29, 1941.

"Section 352 of the Civil Practice Act does not control here. The information in the health commissioner's files concerning the defendant, if there be any such information there, was not acquired by the health commissioner 'in attending a patient in a professional capacity,' nor was the information 'necessary to enable him to act in that capacity.' Although the information may have come to the commissioner from a physician in private practice the transmittal from that physician to the public officer was in obedience to the express command of Section 25 of the Public

Health Law. An intention that these records as to communicable diseases should not be kept confidential is found in the history of this same Section 25. Since 1913 it has provided as to one such disease (tuberculosis) that the report 'shall not be divulged or made public.' In 1939 the Legislature amended the section by naming three other diseases, not including typhoid fever, as to which the reports should be kept secret (see Laws of 1939, chap. 159). It seems to follow that similar reports as to other communicable diseases are not so privileged."

Inquiries

YOUR counsel recently received the following inquiry:

"Dear Mr. Brosnan

"As a member of the State Society, I should like to ask you a question concerning a case at which I shall soon have to appear as a witness.

"A husband is suing his wife, who was a former patient of mine, for divorce on the grounds that she married him knowing that she had syphilis. I believe that they were married in 1931, but I first treated her in 1933. I treated her at intervals through 1935. Her husband was examined by me upon my advice in 1933 and found to be negative, both from the standpoint of physical and serologic findings.

"The wife gave a history in 1933 of having acquired the disease ten years prior to that and had treatment in Montreal.

"In order to avoid saying too much and, therefore, laying myself open to a countersuit by the wife, how much am I allowed to testify? Can you also tell me what the legal method of waiver of the law of privileged communication is? If the Judge informs me that I can testify everything concerning the wife and that he has obtained such a waiver, is this final?

Very truly yours,"

Your counsel replied

"Dear Doctor

"I assume from your letter that you have given no information as yet to anybody concerning your treatment of the wife. In following this course you did absolutely the right thing.

"If you are subpoenaed on the trial and any questions are addressed to you regarding the wife's condition, I would refuse to answer on the ground that this is a matter protected by the Statute regarding confidential communications between patient and physician.

"It would not be necessary for you to take this position if, prior to the trial or on the trial, a written waiver was presented to you signed by the wife permitting you to testify as to your examinations of her, your findings, your treatment, etc. I do not imagine, however, that this waiver will be forthcoming.

"When you have taken the position on the trial above set forth, the Court will then be required to decide whether you should answer or not. If the Court decides that you must answer, that, in my opinion, would sufficiently

protect you since your failure to answer would result in your being placed in jail by the Court for contempt of court.

Very truly yours,"

In answer to an inquiry by a physician who is the director of a hospital, your counsel replied as follows:

"Dear Doctor

"In your letter you ask three questions

"1. This institution is a philanthropic one, devoted to the rehabilitation of the tuberculous. The patients all pay in part or are paid for in part by social agencies or governmental agencies such as departments of welfare. Can such an institution be successfully sued for alleged malpractice on the part of its physicians?"

"Generally speaking, it has been held that a charitable not-for-profit hospital is not responsible for the negligence of its nurses, doctors, or interns in the treatment and care of a patient unless it has failed to use due care in the selection of the particular individual for whose acts the hospital is sought to be held responsible. This rule of law is predicated on the theory that interns, doctors, and nurses are considered independent contractors and not employees of the hospital.

"The hospital, however, may be held responsible, even though it is what is called a charitable not-for-profit hospital, for administrative negligence. If, for example, the hospital authorities permit a dangerous condition to exist in a hospital and a patient is injured thereby, the hospital would be responsible. If the hospital authorities failed to use reasonable care in the conduct of the premises where the hospital is located, the hospital would be responsible.

"2. I am the director of the institution. I have one resident physician who carries on his work in the care of the patients but is under my general direction. Can suit be brought against the resident physician individually for any alleged error or malpractice?"

"The answer to this question is 'yes.' A resident physician can be sued individually for his alleged errors or malpractice.

"3. Are individual members of the board of trustees of such an institution liable for any of the acts of employees of the institution?"

"Generally speaking I should say the answer to this question is that the board of trustees would not be responsible for the acts of em-

ployees. However, there are situations where they would be responsible. For example, if they permitted an employee whom they knew or should know to be incompetent and damage

results, they might well be held responsible. The trustees to avoid responsibility must exercise vigilance in the affairs of the hospital.

Very truly yours,"

AID IN POLIOMYELITIS

The seasonal increase in poliomyelitis demands the utmost vigilance of physicians called to attend "cold" and "upset stomachs," says the *New York Medical Week*. No examination can be considered complete which does not include the neurologic tests that betray the presence of this disease. In view of the importance of early diagnosis, they should be made in all cases presenting any of the symptoms associated with poliomyelitis.

Once a diagnosis has been made, many therapeutic problems arise, particularly in connection with the procurement of necessary mechanical aids. The National Foundation for Infantile Paralysis offers practical assistance to physicians in the solution of such problems. Its offices, at 120 Broadway, have a complete list of "iron lungs" available throughout the country. These adult cabinet-type respirators, of which Manhattan has 24, are not to be confused with such other machines as chest type respirators, resuscitators, inhalators, or aspirators. Physicians desiring to locate one in an emergency will be glad to know where this information is available.

An equally important service offered by the Foundation is the free distribution of Toronto splints and Bradford frames for indigent patients. The central supply depot in New York City is prepared to meet any requests for such aid in behalf of the needy. No charge is made except for expressage.

It is not anticipated that the current seasonal rise in poliomyelitis will reach serious proportions. Nevertheless, the profession must be on its guard and prepared to institute proper treatment at the earliest possible moment. To physicians whose practice lies principally among the poor, it is a comfort to know that the National Foundation for Infantile Paralysis is prepared to supply their indigent patients with necessary therapeutic devices, which it might otherwise be impossible for them to obtain.

THE VANISHING HOME

Unfortunately, the home has become merely a place to go when everything else is closed, remarks Dr. M. A. Austin in *Clinical Medicine and Surgery*. A person is born in a hospital and is given a superficial education in schools that President Hutchins, of Chicago, says are the worst in the world and have the poorest teachers. The children go through adolescence in automobiles and, if lucky, are married in a church, they live in an apartment and entertain at a picture show, they eat at a drugstore, die in a hospital, are buried from a mortuary, and stored in a mausoleum. The only "God Bless Our Home" motto that I know of is in a museum. The responsibility of parenthood has been taken over by the state and a mother's pension. The responsibilities of one's parents is also a state function now, with old-age pensions. And too soon, I fear, the family physician will be merely a medical technician, subsidized by the government and as impersonal as his probable ally, the unemployment relief part of the social security setup.

We have made medicine such a nightmare to the laity by publicizing its attainments in unusual cases that the layman has developed a doctor phobia. Our various campaigns have undoubtedly done far more good than harm in giving information about tuberculosis, syphilis, cancer, and pneumonia, but with the demand for an early diagnosis is the inevitable accompaniment that this diagnosis and the treatment of these conditions take both time and money. As a direct outcome of this propaganda, the treatment of these patients has become more and more a state function.

I went through the influenza epidemic at Camp Custer during 1918, and in one day 141 boys died. In my opinion, as many of them died because of their environment as from the disease. The same hospital fear is engendered in many patients who die in hospitals.

LIST OF DISEASES UNDER INVESTIGATION

Rockefeller Institute for Medical Research issues the annual list of diseases under investigation in its hospital during 1941-1942, no charges being made for treatment, room, board, or any other services.

1 Bright's Disease—Children and adults with the nephrotic syndrome, and with nephritis in the early stages. 2 Heart Disease—Advanced heart failure. 3 Rheumatic Fever—Children (ages 6 to 12) in inactive stage of this disease, whose parents are willing to bring them to the Outpatient Clinic monthly, from October until June. 4 Acute Respiratory Diseases—

Acute lobar pneumonia and acute bronchopneumonia in adults, both preferably in early stages. An oxygen chamber is available for suitable patients. 5 Neurotropic Virus Diseases—Acute encephalitis and aseptic meningitis. 6 Nutritional Diseases—Advanced non-malignant diseases of the liver, and muscular dystrophies and atrophies.

Physicians should communicate by telephone (REgent 4-8000) or by personal application to the Resident Physician before sending patients to the hospital. An ambulance will be sent when necessary.

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Albany A card party and bake sale was held at the auditorium of St. Peter's Hospital. Mrs. Herman Rosenblatt was general chairman, assisted by Mesdames John Horner, Daniel B. Lynch, Daniel O'Keefe, Darwin A. Bruce, Almer T. George, Daniel F. Hannon, Stanley E. Alderson, Donald D. Prentice, and Joseph V. Tobacco.

Columbia. The auxiliary opened with the fall meeting October 21, 1941, at Rainbows End, Valatie, with Mrs. George B. Adams, state president, as guest speaker. Following the famous Rainbows End luncheon, Mrs. Bowerhan, county president, opened the business meeting.

Mrs. R. P. Harris read a letter on behalf of the local chairman of Bundles for Britain thanking the auxiliary for their cooperation. Mrs. Henry J. Noerling, Sr., reported the meeting of the State Executive Board which was held in Auburn. Mrs. Joseph Gold, chairman of county legislative committee, attended a meeting at Mrs. Alfred Madden's home at Albany. Mrs. T. E. Bullard, president of Saratoga County, gave a short humorous talk, giving the reason for her belief that Columbia County is one of the best—referring to a lasting memory picture from a story related to her when she was a child.

Mrs. Adams paid tribute to Mrs. S. R. Reed, of Texas, who twenty years ago, before there was a National Auxiliary, established an auxiliary in Texas, feeling that the doctors' wives had a definite place behind the doctor as an auxiliary helper. The first idea of an auxiliary was, perhaps, that of sociability, but it now has a strong educational side. Auxiliary members should educate themselves in matters of health because it is their job to educate the public. There is also the service side—cancer control education program, health in the schools, tuberculosis work, and work for Red Cross and Bundles for Britain.

In her very interesting talk that was so much enjoyed, Mrs. Adams traced the growth of the auxiliaries in this state saying that "in six years the counties have grown from five to twenty-nine with a membership of over 2,000. There should be a friendliness, a unity of purpose in an auxiliary, the members should be well informed and they should be ready when called upon to assist the medical profession."

Contract bridge followed, attractive awards going to those with high scores. Those who attended the luncheon meeting were Mrs. George B. Adams, of Auburn, president of the State Auxiliary, Mrs. G. Scott Towne, of Saratoga, past-president of the State Auxiliary and now State Director, Mrs. Albert Vander Veer, of Albany, state recording secretary, Mrs. F. Leslie Sullivan, of Scotia, state treasurer, Mrs. Alfred Madden, of Albany, state legislative chairman, Mrs. J. J. Clemmer, of Albany, past-president of Albany County, Mrs. A. Tidd, of Auburn, Mrs. T. E. Bullard, president of Saratoga County, and Miss Frances Towne, of Saratoga. Members present were Mesdames Robert L. Bowerhan, Hugh G. Henry, Leonard Car-

penter, Harry Pattison, Henry J. Noerling, Sr., Henry J. Noerling, Jr., L. J. Byron, Cecil L. Schultz, Ralph F. Spencer, William D. Collins, John L. Edwards, R. P. Harris, Clark Rossman, O. H. Bradley, Joseph P. Gold, W. L. J. McDonald, and Harold Levine.

Erie. The county auxiliary has made a good start, with a busy program ahead. At the meeting on September 28, in addition to the regular program, Mrs. John D. Taylor, a member of the Emergency Volunteer Services and co-chairman of the Volunteer Activities in the Buffalo Defense Council, explained the working of the Volunteer Services and, in accord with their Executive Board, the membership at large voted to make this one of their projects for the year.

On October 2, twenty-five women of the auxiliary went via bus to the Eighth District meeting at Jamestown. There they enjoyed the hospitality of the newly formed Chautauqua Auxiliary. They also enjoyed meeting again Mrs. George B. Adams, state president. The program committee is sponsoring a book survey by Mrs. Ethel Holmes Munsey. The book to be surveyed is "My Scottish Husband," by Lady Neish. The proceeds of this project will go toward their gift to the Physicians' Home. On November 6 the auxiliary celebrated its second birthday with an informal dinner-dance in the Terrace Room of the Hotel Statler. The husbands of members were honored guests. A good time was had by all who attended.

Nassau. The program in advance is as follows: Meeting, November 25, Nassau Hospital Auditorium, 8:45 p.m., speaker Dr. Legrand Kerr, Brooklyn, "Dames, Doctors and Doings in the Drab Nineties." December 6, Medical Society and Auxiliary Dinner-Dance. December 16, Nassau Hospital Auditorium, 8:30 p.m., Auxiliary Christmas Party. January 27, Nassau Hospital Auditorium, 8:45 p.m., moving pictures shown by Dr. Eugene H. Coon. February 24, Cathedral House, 9:00 p.m., combined county medical society and auxiliary meeting, speaker Dr. Richard Brickner. March, Cancer Institute. April 28, 2:00 p.m., excursion to Meadowbrook Hospital, speaker Dr. A. J. McRae. April 27-30, New York State Medical Convention, Waldorf-Astoria, New York City. May 26, Nassau Hospital Auditorium, 8:45 p.m., auxiliary annual meeting. June 8-12, A.M.A. Convention, Atlantic City. June 17, auxiliary luncheon and bridge at 12:30 p.m.

Queens. At the Medical Building, Forest Hills, one of the largest membership teas in the history of the auxiliary was held. The hall was beautifully decorated with autumn leaves and flowers, and the large tea table with its glistening silver and centerpiece of roses was most inviting. Mrs. William Godfrey, president-elect, and Mrs. Raymond Murphy, past-president, poured. Mrs. Michael M. Schultz, president, welcomed the members and guests and thanked Mrs. Edwin Core, chairman of membership, and her commit-

tee Miss Virginia Gildersheue Shuey, 15-year-old concert pianist and daughter of Dr and Mrs Paul Shuey, of Jackson Heights, rendered several classical selections. About 150 attended, twenty new members were interviewed.

At 8 30 P.M. the regular monthly meeting was held, with the president, Mrs Michael M. Schultz, presiding. After all the reports were read, Mrs William LaVelle, chairman of program, introduced the speaker of the evening, Mrs Wilbur Surbur, whose topic was "Marketing, Your Hobby." Mrs Frank Mozzola was hostess for this meeting.

Rensselaer Mrs. Marion L. Fahey, executive secretary of the Rensselaer County Tuberculosis and Public Health Association, outlined a plan whereby persons hiring domestic help will be asked to hire only those who can produce certificates showing them to be free of communicable diseases. If prospective employees have no such certificates, they should be asked to secure one from the clinic or the family physician. The auxiliary approved the plan and will name a com-

mittee to work with Mrs. Fahey and Dr Fred T. Cavanaugh of the county medical society in carrying it out.

"Nutrition in Defense" was the topic of an address by Miss Mabel A. Milhan, Rensselaer county home demonstration agent. Mrs. John J. Rainey, auxiliary president, presided. Mrs. Rainey reported on the meeting of the State Executive Board. A nominating committee to report at the next meeting was selected. Mrs. Victor C. Jacobson, chairman, Mrs. Stephen H. Curtis, vice-chairman, Mrs. John F. Russell, Mrs. Minnie B. Stannard, and Mrs. James H. Donnelly. Two new members were admitted to the auxiliary: Mrs. James H. Donnelly, Jr., and Mrs. Eugene J. Hanratta, Jr. Tea was served at the conclusion of the meeting, with Mrs. John J. Quinn and Mrs. Fred T. Cavanaugh pouring. Those who served included Mrs. Minnie B. Stannard, chairman of the hospitality committee, Mrs. John F. Russell, Mrs. Eugene J. Hanratta, Jr., Mrs. James H. Donnelly, Jr., and Mrs. John J. Noonan, Jr.

THE PRIME DILEMMA THROUGH ALL MEDICAL HISTORY

has been whether to tell the truth to a fatally ill patient, says an editorial in the *Journal of the Medical Society of New Jersey*.

There are those who believe that no good ever comes out of deception, that it is more honest and more humane in the long run to tell a patient that he is the victim of an incurable or inevitably fatal disease. There are those who say that such a practice is not only cruel but inaccurate, since tomorrow some new remedy may come into our ken which will remove a disorder from the classification of the hopeless to that of the treatable.

Patients themselves usually say "Tell me the truth, Doctor, I'd rather know, and I can take it." It is doubtful, however, whether even the sturdiest wants to have a death warrant read to him.

This much seems incontrovertible: the physician who discovers or diagnoses a hopeless ailment must transmit that information to some

responsible member of the family. To tell the patient that he is doomed to an early death, however, seems pointless, for it is impossible to see any good that could come out of such a procedure except in a small group of cases in which rearrangement of a man's business affairs might make for financial security in his family. Even in these cases it would seem sufficient to tell the patient that he would be too sick to carry on his business for a long time, and that he should adjust his affairs accordingly.

To transmit a verdict of inevitable death under any other circumstances, however, appears utterly without justification except perhaps the abstract one of rigid truthfulness, no matter what the cost. Since the emotional state of the patient is so large a factor and since the hopelessly sick patient has so few comforts, there would appear to be no justification for taking from the tiny reservoir still available, that one last blessing in Pandora's Box.

CARDIAC CLINICS TO BE HELD

A scientific session of the Committee on Cardiac Clinics of the New York Heart Association will be held Tuesday, November 25, at The New York Academy of Medicine, New York City. The meeting will start at 8 30 P.M. Dr Cary Eggleston, associate physician at New York Hospital, will preside. Three papers will be presented: "Measurement of Cardiac Output by the Ballistocardiograph and the Direct Fick Method," by Dr Hilmert A. Ranges, Department of Medicine, New York University College of Medicine, and Dr Andre Cournand, Depart-

ment of Medicine, College of Physicians and Surgeons, Columbia University, "Concentration of Carbon Dioxide in Expired Air in Normal and Cardiac Patients," by Drs Cameron Bailey and Paul Boyer, New York Post-Graduate Medical School, "Angiocardiograph in Congenital Heart Disease," by Dr Marcy L. Sussman, radiologist at Mount Sinai Hospital.

The session will be open to physicians and medical students without charge. The New York Heart Association is a division of the New York Tuberculosis and Health Association.

THEY CALLED IT

Revolutionary

—when, five years ago, G. E. introduced this radically different design in roentgen therapy apparatus—the G-E completely oil-immersed, shock-proof Maximar.

True, it was a revolutionary step in x-ray engineering—necessarily so, in order to obtain the important technical advantages here realized, which would also make it economically feasible for more institutions to equip for a thoroughly efficient x-ray therapy service, and thus make treatments conveniently available to more people in more communities.

The fact that in five short years the Maximar has come into world-wide use is tangible evidence of its eminently successful design. And the records of performance and maintenance costs on these hundreds of installations tell a story of immediate interest to every prospective buyer of therapy equipment.

Since there are now four Maximars available—the 200 Kv., 220 Kv., 250 Kv., and 400 Kv. models—you can readily select between them according to the specific type and range of therapy service you have in mind. Moreover, our experienced engineers stand ready to draw up a floor plan to show you how a Maximar can be most practically adapted to the space you have available.

Write today for information helpful to your preliminary planning.

REVIEWED

A Textbook of Ophthalmology By Sanford R Gifford, M D Second edition Octavo of 470 pages, illustrated Philadelphia, W B Saunders Company, 1941 Cloth, \$4.00

This book is printed in clear type on good paper. It is replete with illustrations, the majority of which are actual photographs. The 14 color plates are remarkably good for a volume of this size. The subject of ophthalmology is surprisingly well covered, the chapters on the large phases of the subject, such as cataract, glaucoma, ocular motility, fundus changes in cardiovascular renal diseases being quite adequate for the author's purpose in presenting this book to the student and general practitioner.

As would be expected in a second edition, some chapters have been rewritten, some illustrations have been left out and new ones added, and the subject has been brought up to date in line with advances during the three years since the first edition appeared. In ocular therapeutics the use of the newer drugs for chemotherapy and the broadened use of the vitamins have been presented. As would be expected of the author of a book on ocular therapeutics, treatment of the various conditions in this book is well covered.

This is a readable, simple, and concise presentation and should prove valuable both to the student and for the general practitioner for whose use it is especially intended. It is to be hoped that its perusal by the latter especially will lead him not to think himself an ophthalmologist but to recognize the ocular conditions that require the aid of one to the furtherance of the eye health of his patients.

E CLIFFORD PLACE

Man's Greatest Victory over Tuberculosis By J Arthur Myers, M D Quarto of 419 pages, illustrated Springfield, Charles C Thomas, 1940 Cloth, \$5.00

Another excellent book has arrived from the prolific pen of Dr J Arthur Myers. This book deals almost wholly with the historical aspect of the fight upon tuberculosis in animals. One can hardly conceive a more complete recording of the step-by-step progress that has been made in the control of this disease. While this particular book confines itself largely to the character of the efforts made in control of cattle tuberculosis, one is tremendously impressed with the fact that a technic has been evolved which if carried out to its logical conclusion should eventuate in the eradication of tuberculosis in man as well as in cattle.

Here is a book no student of medical progress should be without. It epitomizes the monumental work that has been done here in the United States to eradicate tuberculosis as a social and economic problem.

FOSTER MURRAY

The Heart in Pregnancy and the Childbearing Age By Burton E Hamilton, M D, and K. Jefferson Thomson, M D Octavo of 402 pages, illustrated Boston, Little, Brown and Company, 1941 Cloth, \$5.00

This volume represents a review by Drs Hamilton, Thomson, and Irving of cardiac

patients treated during pregnancy at the Boston Lying-In Hospital over a seventeen-year period.

Rheumatic heart disease was found to be the most prevalent type of cardiac involvement constituting the etiologic factor in 92 per cent of the number of pregnant women with cardiac involvement. Congenital, syphilitic, and degenerative lesions, along with deficiency heart disease, were the causative factors also encountered in this series.

Prophylactic treatment and the treatment of cardiac failure is thoroughly discussed. Post-partum complications are considered. The heart in toxemias of pregnancy is thoroughly covered. The normally pregnant patient is compared with the pregnant cardiac patient. Case reports are included to review the subject. It is a reliable, sane résumé of an important phase of obstetrics.

JAMES F BUTLER

Radiologic Physics By Charles Weyl, S Reid Warren, Jr, and Dallett B O'Neill Octavo of 459 pages, illustrated Springfield, Charles C Thomas, 1941 Cloth, \$5.50

This book was written as a text to be used in the courses in radiology given in the Graduate School of the University of Pennsylvania. As such, the book probably serves its purpose well. It covers all the necessary electrophysics required for an understanding of modern x-ray equipment. The book is divided into two parts. The first deals with the more general principles of electricity, electromagnetism, and electronics. The second part considers the more direct application of these principles to x-ray and further discusses such matters as principles of technic development, and stereoscopy.

The book's chief defect lies in the brevity of most of its presentations. For proper use of the volume one requires either an instructor to provide additional background material or a good physics text must be always at hand and be studied in conjunction with the main work. To meet this requirement the authors have included a comprehensive bibliography at the end of each chapter. In addition, in the appendix there is a brief review of the mathematical concepts necessary for an understanding of the book.

The volume indicates clearly all the material that should be learned for a good working knowledge of radiologic physics and, if used in a course or together with more detailed texts, it serves its purpose admirably.

A L L BELL

A Diabetic Manual for the Mutual Use of Doctor and Patient. By Elliott P Joslin, M D Seventh edition Duodecimo of 238 pages, illustrated Philadelphia, Lea & Febiger, 1941 Cloth, \$2.00

This book fulfills its title very well. It is the seventh edition of an original and classic manual of its type. It is rich in scientific material and practical suggestions. It abounds with clinical considerations, and one will find of particular interest case reports with their follow-up.

FALKIRK IN THE RAMAPOS

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES Falkirk has been recommended by the members of the medical profession for half a century.

Literature on Request

ESTABLISHED 1889

THEODORE W. NEUMANN, M.D., Phys.-in-Chg
CENTRAL VALLEY, Orange County, N. Y.

AN AMERICAN HOSPITAL IN THE WAR ZONE

America's aid to Great Britain covers more than materials of defense and offense—more than the daily needs of civilian relief.

An American Hospital in Britain, staffed completely by American doctors, nurses, and technicians and maintained by American contributions, has been in operation since September, 1940. Since the day it opened, more than 2,600 severe air-raid casualties have been treated at the hospital and the American surgeons have performed over 1,400 operations. Most outstanding has been the work on severe bone fractures so common among victims of bombings.

The technique developed by the American doctors in the treatment of these cases has been so successful that it has attracted the attention of medical men in all parts of the island kingdom. Many British doctors have sought the opportunity to watch and study the technique of their American colleagues.

Plastic surgery and skin-grafting have also taxed the skill of the hospital staff, especially among patients from the air force who have been burned about the hands and face when bailing out of flaming planes. Other delicate operations performed with remarkable results include those of brain and spinal cases.

The delicate brain operation that restored the power of speech to a 7-year boy struck dumb by bomb injuries, and which became international news, is but one example of what the American Hospital calls a regular performance in the line of duty.

This tremendously important experience in war surgery is being made available to America for our own defense measures through the records which are being turned over to the Committee on Wound Infection of the National Council of Medical Research in this country.

Pioneer work in compound fracture treatment, brain and spinal operations, plastic surgery and skin grafting, at the American Hospital, is supplying a medical program valuable to America's defense plans.

The fine work done will be materially expanded in January, 1942 when the hospital moves to larger quarters at Oxford. Here it will take over a new hospital building of 200 beds, and its staff will be increased by some 60 new members recruited in America.

The cost of operating the American Hospital for 1942 has been estimated by the British War Relief Society of America, at \$300,000. The hospital has been wholly supported by contributions made through this Society.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets, and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates: \$18 to \$35 Weekly. MRS. M. E. MANNING, Supt. - TEL: Rockville Centre 3660

[Continued from page 2268]

General considerations, as well as specific problems pertaining to diabetes, are presented in a clear and concise manner. Its small cost makes it possible for all physicians, as well as diabetic patients, to include it among their current books.

E R MARZULLO

The Principles and Practice of Ophthalmic Surgery By Edmund B Spaeth, M D. Second edition. Octavo of 886 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$10.

The second edition of *Principles and Practice of Ophthalmic Surgery*, coming so soon after the first, not only speaks for the popularity of this work but demonstrates beyond a doubt that it is authentic in its field.

The present volume has been brought up to date not only by elaboration of the text but by the addition of numerous illustrations.

The reviewer is particularly impressed by the logical plan of this book, by its orderly presentation of each problem, and by the step-by-step sequence of each technical description.

This arrangement makes the book ideal as a study text for the ophthalmic resident and yet makes readily accessible any aspect of a problem which the "arrived" ophthalmologist may choose to brush up on before he enters the operating room.

The illustrations, with but one or two exceptions, are readily understandable and the diagrams, charts, and tables are a decided asset in supplementing the text.

The author has quoted directly from other authorities in many instances, thereby showing his lack of bias in favor of his own ideas to the exclusion of others. This plan of a broad and inclusive point of view has resulted in a much wider scope than other similar works that have set forth only one man's ideas and experiences.

Because of this, the reviewer would think it justifiable to call this work of Doctor Spaeth's, the "Bible of Ophthalmic Surgery."

JOHN N EVANS

The New International Clinics, Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts Edited by George M Piersol, M.D. Volume II, New Series Four. Octavo of 299 pages, illustrated. Philadelphia, J B Lippincott Company, 1941. Cloth, \$3.00.

This issue of the *New International Clinics* contains ten miscellaneous original contributions and two symposiums, one from Yale and the other from the University of Louisville. The comprehensive review is that by Tumen and Lieberthal of chronic gastritis. Special mention should be made of the excellent articles on the treatment of bronchospastic dyspnea by Wendkos and Robertson and that on cryptorchidism by Hamilton and Hubert.

MILTON PLOTZ

Pharmacology By J H Gaddum, Sc D. Octavo of 407 pages, illustrated. New York, Oxford University Press, 1940. Cloth, \$6.00.

This book is devoted, as the title would suggest, almost exclusively to pharmacology. In

it one finds an authoritative discussion of sound physiologic and pharmacologic principles.

A study of the general principles so clearly presented in this work would fortify the physician against the unscientific and extravagant claims made for so many drugs.

CHARLES SOLOMON

An Introduction to Dermatology By Richard L Sutton, M D, and Richard L Sutton, Jr, M D. Fourth edition. Octavo of 904 pages, illustrated. St Louis, C V Mosby Company, 1941. Cloth, \$9.00.

This book is a condensed volume from the authors' tenth edition of *Diseases of the Skin* and contains approximately 800 pages of text with over 700 photographic cuts including many photomicrographs. Thirty-five pages of bibliography are appended, arranged according to chapters, under disease headings, and set up so that they make an easy, ready reference. These references are, of course, only the outstanding ones applying to the subject and are completely up to date.

Anyone who has read the authors' more comprehensive text will appreciate that while this book is written for the student and general practitioner, it is complete and well written. It is not a compend, nor does it omit a great number of the less common diseases. The only abridgement is found in lengthy description of variations, in theories of etiology, and in ideas of therapy.

The reviewer heartily endorses this as an excellent book, more than sufficiently complete for all but the specialist and research worker. In fact it could even be used by them for its concise capitulation of pigmentations, lymphoblastomas, gangrene of the skin, etc.

E ALMORE GAUVAIN

Air Raid Precautions (In Ten Parts.) Reprinted by Permission of the Controller of His Britannic Majesty's Stationery Office. First American Edition. Octavo. Brooklyn, Chemical Publishing Co, 1940. Cloth, \$3.00.

Air Raid Precautions is an American edition from the Great Britain Ministry of Home Security. The volume is in ten sections and is expertly prepared by various civil and military groups who have had the most recent experiences in air-raid defenses.

Duties of the municipal services, including the Fire and Police departments and various other civil and volunteer units, are outlined, as well as the multiplicity of personnel training prior to attacks, classifications of buildings, etc., as to ability to withstand bombardment, and the planning and construction of shelters. Emphasis is placed on the type of equipment to issue and its care, inspection, repair, and storage.

Two sections are devoted to gas detection and identification service, care and inspection of respirators and individual equipment, and special protective clothing against chemical warfare agents.

Air Raid Precautions is a valuable guide for any individual or municipality interested in such a service.

BOTTLENECK OF FATIGUE

A gentleman in the West remarks that "Pleasure travel is playing a vital role in relieving the strain of overwork in the national defense emergency. Men cannot work like machines. A vacation of pleasure travel is proving the cure for the danger of a bottleneck of overworked executives."

Maybe the gentleman from California has something there. If it isn't true as yet, physicians will undoubtedly, as time goes on, have an increasing number of patients who have cracked under the strain. The cure may not be as simple as this travel-minded gentleman would have us all believe, but as every physician knows, a trip of even one day away from the grind certainly is an adjuvant in treating frayed nerves and tired mind and body.

In addition, as this man explains, "Travel makes better Americans. It is a marvelous thing for people to travel over and know their own state. It is still better for them to travel over their own country. A person traveling over the United States from the Alleghenies to the Pacific learns to appreciate his part-ownership of the most valuable real estate on earth. He learns to know America. And when you know America, you won't let anything happen to America."

"We need only to look at Canada," he adds, "which has been at war for two years. There every effort is being made to encourage travel and recreation, for every Canadian realizes the vital necessity of keeping himself physically and mentally fit to do his or her share."

SLEEP IN SEASON

In an article setting forth new rules for sleeping, an Australian newspaper states that we are seasonal sleepers—that wintertime sleep is not the same as slumbers at other times of the year.

"You will fall asleep most easily in the spring, and you will move around less and dream more."

"You will have the hardest time to go to sleep in summer."

"In the autumn it's all turned around. You'll move around more, and will do less dreaming than at any time of the year."

Weather, too, affects sleep according to the news article. As the barometer goes down, restlessness goes up. The soothing monotone of rain falling on the roof may induce slumber, but a person will probably be more restless on a damp night.

CUSS WORDS AID BOMB VICTIMS

Not that railwaymen are any more addicted to profanity than the ordinary run of mortals, but the Queen's Canadian fund received an unexpected contribution when a Canadian National train crew fined themselves every time a naughty word slipped out. By mutual consent it was agreed that any member of the crew who said "S—%—1/2—" or "S—%—1/2—" (literal translation "oh fudge!" and "dear me!") would place a penny in a box.

When the train reached Moncton terminal, the box was filled to overflowing so \$9.56 went to aid bomb victims in Britain.

ANDREW M BABEY

Textbook of Pediatrics By J P Crozer Griffith, M.D., and A. Graeme Mitchell, M.D. Third edition. Octavo of 991 pages, illustrated Philadelphia, W B Saunders Company, 1941 Cloth, \$10

The third edition of this textbook has been revised from cover to cover. Its name has been changed from *Diseases of Infants and Children*. It stands as one of the two best general books on pediatrics for students in this country.

Like most modern textbooks, collaborators have greatly aided, so that special fields of endeavor have been covered by those who have done special work in a particular field. The book was rewritten by Dr Mitchell and various chapters were sent to the collaborators for criticism and advice. Thus, the style remains the same throughout.

There is no bibliography for this edition. The authors thought it would be too bulky in a single volume—that is, if it were complete. However, a bibliography of the edition can be secured by writing to the Society for Research in Child Development, National Research Council, 2101 Constitution Avenue, Washington, D C.

Since receiving this book for review, both authors have died. No greater monument than this book could be erected to these great and beloved teachers of pediatrics. Dr Griffith lived to be an elderly man and he saw the field of pediatrics develop from its infancy, while Dr Mitchell was in the prime of a wonderful teaching career.

THURMAN B GIVAN

The Story of Clinical Pulmonary Tuberculosis. By Lawrason Brown, M.D. Octavo of 411 pages. Baltimore, Williams & Wilkins Company, 1941 Cloth, \$2 75

During the many years that Dr Lawrason Brown lectured at the Trudeau Post-Graduate School for Pulmonary Tuberculosis, he delivered a series of talks on the "Historical Aspect of the Clinical Study of the Disease." These lectures embrace knowledge of the subject from the time of the earliest discoveries to those of the present time. They proved to be of absorbing interest to those privileged to hear them and, on the urging of many friends, Mrs Brown has brought these lectures together and published them in a single volume, much to the advantage of us all.

The book is divided into four parts. The first part is episodic in character, dealing with events coincident with existing knowledge in and about the years 1700, 1800, and 1900. The second part deals with "Diagnosis of Early Pulmonary Tuberculosis," stressing particularly the contributions of Laennec and his successors, "Early Publications in Germany and Austria," "The Diffusion

of Knowledge in England", "Diagnosis in America", and, last, a chapter on "Diagnosis by X-Ray." This last chapter was contributed by Dr Brown's close associate, Dr Homer L. Sampson. The third part deals with the "Modern Surgical Treatment of Pulmonary Tuberculosis," stressing largely the evolution and development of surgical methods in general. Much of this chapter has been written by Dr Edward W Archibald, of Montreal, Canada. The fourth part of the book is devoted to some sidelights of importance—namely, "Laennec and His Writings," "The Story of the Stethoscope," and "Early Medical Journals."

The book as a whole is highly readable, is extremely well documented, and has a most complete bibliography. It is invaluable to the student of pulmonary tuberculosis.

FOSTER MURRAY

Brucellosis (Undulant Fever) Clinical and Subclinical. By Harold J Harris, M.D. Octavo of 286 pages, illustrated. New York, Paul B Hoeber, Inc., 1941 Cloth, \$5 50

Brucellosis is a disease concerning which there is a growing interest on the part of the medical and veterinary profession, as well as the public health authorities. This book is, therefore, timely and informative. It may very well be expected to focus attention on this infection, which is desirable because of the controversial nature of so much that has been written concerning it. The author describes the various aspects of the disease in their logical sequence, giving many personal observations and quoting from many of the authors whose publications are listed in the appended bibliography. Although he makes mention of a personal series of 249 cases, certain of which he cites to illustrate points made in the text, Dr Harris has not included an individual tabulation of his patients by age, sex, occupation, suspected mode of infection, diagnostic proofs, symptoms, complications, etc. He has attempted, however, the important task of bringing forth to more searching scrutiny the subject of chronicity, or latency, as related to the brucella infection. In this he shows keen alertness to its public health significance, as well as to the realization that one of our main problems is to define clearly this disease. As Henry Dietrich has said "Undulant fever is without pathognomonic symptoms or clinical signs, and one is dependent on a reliable laboratory for a final decision in a given case." Even tissue diagnosis, as Dr Harris agrees, is not yet of practical value, and the necropsy observations that have reached the literature are practically negative, at least for specific findings. In contradistinction to other milk-borne diseases, like typhoid and septic sore throat, it is rarely possible to trace the suspected outbreak to a given dairy. Even all the laboratory procedures used for its diagnosis are subject to a variable interpretation with the exception of a positive culture, and this is admittedly difficult to obtain and infrequently found. Most all statistical and serologic evidence tends to establish that brucellosis (Brucella abortus), is most infrequent in children under 10 years of age, although they are the greatest consumers of milk. On the contrary, the diagnosis is rather commonly made among those

A Way to Collect Money—Though Not Recommended

Ghandi's custom of fasting as a protest may appear useless to Western ways of thinking, but to the Hindu is the "mode" of asserting one's right to redress. Throughout India of old, the practice of "sitting harna" was resorted to by creditors against their debtors who had defaulted, and in some parts of that country the practice is still in vogue.

There the creditor places himself before the door of his

debtor, there to remain until the debt is paid. The expected payment is seldom delayed for public opinion would instantly and severely punish the debtor who allowed his creditor to become exhausted or to die of starvation before his doorway.

It may work in less calloused nations, but it is not to be recommended here for who would want to sit out the payment of our rising public debt?

Baldness Always a Hair-Raiser

Baldness has baffled the human race since the beginning of the lowest form of civilization, and perhaps has provoked more remedies than any malady the human race has ever experienced.

Some five thousand years ago they had remedies for this bane of man, but oddly enough the first recorded prescription was for a woman—for Ses, the mother of Teti who was King of Upper and Lower Egypt. It is to be

found in the famous Ebers Papyrus, a medical treatise still in the possession of the University of Leipzig unless it was burned in one of Hitler's purges of non-Aryan literature.

While testimonials as to its efficacy are lacking, it did have some rather impressive-sounding ingredients. The prescription called for such "drugs" as "toes-of-a-dog," "refuse-of-dates" and "hoof-of-an-ass."

ELIXIR BROMAURATE

IS GIVING EXCELLENT RESULTS

IN WHOOPING COUGH

Shortens the duration of the cough, relieves the distressing spasms and gives the child rest and sleep. ENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles.

Also valuable in other PERSISTENT Coughs. Teaspoonful every 3 to 4 hours.

adults who handle infected animals and their carcasses. The evidence would seem clearly to suggest a contact infection. Much information is needed, however, before too many conclusions are drawn as to prophylaxis and dissemination of a disease, the clinical aspects of which we possess so little knowledge.

JOSEPH C REGAN

I. *Help Your Doctor to Help You When You Have Sick Headache or Migraine* Duodecimo of 37 pages. New York, Harper & Brothers, 1941. Cloth, \$0.95

II. *Help Your Doctor to Help You When You Have Colitis* Duodecimo of 30 pages. Cloth, \$0.95

III. *Help Your Doctor to Help You When You Have Food Allergy* Duodecimo of 50 pages. Cloth, \$0.95

IV. *Help Your Doctor to Help You When You Have Gallstones and Diseases of the Gall-bladder* Duodecimo of 41 pages, illustrated. Cloth, \$0.95

V. *Help Your Doctor to Help You When You Have Gastric or Duodenal Ulcer* Duodecimo of 53 pages, illustrated. Cloth, \$0.95

The purpose of this series of small booklets is to provide manuals of the type that a doctor might want to give to his patients in order to supplement his verbal explanations and instructions.

I. "Migraine"—This is clearly and well written. One wonders why it was necessary to tell the patient where his physician could find the latest therapy on the subject (Shouldn't the physician know or find out for himself?) It seems to the reviewer that the text strays a bit too widely from its avowed purpose when it lists and suggests simple, as well as proprietary, drugs used in treatment of this condition.

II. "Colitis."—This is a most sensibly written little volume. It discusses "so-called colitis" and exposes much of the "hokum" surrounding it. Sane and wholesome advice to those who suffer from this disturbance is given. This material is worth reading by many doctors and by high-strung persons suffering from occasional or frequent "bellyaches" with or without diarrhea.

III. "Food Allergy"—"Fitting the diet to the individual" is the essence of the advice given in this little book. This difficult and complex problem is handled in a masterful way. This again is a volume from which both sufferer and doctor can profit greatly.

IV. "Gallstones and Diseases of the Gall-bladder"—It would seem that too much detail is given to the lay person about x-ray diagnosis. The discussion of technical diagnostic methods and criteria is overstressed. This volume was apparently written by a surgeon, who discusses the case for and against immediate and future surgery intelligently, he says actually and perhaps in truth, "there is no medical treatment for this disease."

V. "Gastric or Duodenal Ulcer"—For lack of a more modern and probably more rational treatment for ulcer, the author adequately discusses frequent feeding, neutralization of acid, and the like in the handling of this condition. Sticking to the Sippy routine, as he does, appears a bit unprogressive in the light of recent knowl-

edge. The indications for surgery are well discussed. The inclusion of ulcer-like diseases, as well as the outlook for possible improvement by medical therapy in the near future, seems wise.

In general, one can say that these five booklets are valuable adjuncts to the physician in the necessary explanations given to the patient about his condition. Both editors and authors must ever keep in mind that narrow, dangerous dividing line beyond which they must not go, particularly in advising specific treatment, lest they permit the booklets to become competitors of the doctor.

BENJAMIN M BERNSTEIN

Cardiac Classics. A Collection of Classic Works on the Heart and Circulation with Comprehensive Biographic Accounts of the Authors. Fifty-Two Contributions by Fifty-One Authors. By Frederick A. Willius, M.D., and Thomas E. Keys, M.A. Quarto of 858 pages, illustrated. St. Louis, C. V. Mosby Co., 1941. Cloth, \$10.

Physicians interested in diseases of the heart and circulation will welcome the appearance of *Cardiac Classics*. The authors have made wise selections from the vast amount of original material dealing with cardiology, placing in one volume the observations of many of the masters. The book is entertaining, but more than that it is of value in locating source material. Its use may stimulate others in the field of historical medicine. It will be of value to the teacher because in it he can find just what Austin Flint said about his murmur, Durozier about his sign, and Fallot about his tetralogy. The short biographic sketches about each author are well written, and the illustrations accompanying them help the reader to picture what manner of men were pioneers in cardiology.

EDWIN P. MAYNARD, JR.

A Short History of Psychiatric Achievement With a Forecast for the Future By Nolan D. C. Lewis, M.D. Octavo of 275 pages. New York, W. W. Norton & Co., 1941. Cloth, \$3.00.

This is a small and yet painstaking review tracing the development of psychiatry through the ages. It is a historical survey and yet a most comprehensive scientific analysis of the types of thought and evolution of principles that have been the basis for the development of present day psychiatric achievement. It is interesting reading and is recommended alike to the student of medicine, the practicing physician, and the psychiatrist.

ABRAHAM M. RABINER

The Medical Clinics of North America. July, 1941. Volume 25, Number 4. (Mayo Clinic Number) Octavo. Illustrated. Philadelphia, W. B. Saunders Company, 1941. (Six numbers a year) Cloth, \$16 net, paper, \$12 net.

The July number of the Clinics will appeal chiefly to the specialist in radiology, for it is devoted entirely to diagnosis and treatment by x-rays and radium. Three more or less clinical articles on ulcers and intestinal obstruction will be of interest to the internist and general practitioner.

Editorial

Common Sense

For pure, unadulterated common sense we commend the editors of the *Woman's Home Companion* for their editorial comment on the alleged bad health of American youth as supposedly revealed by the medical examinations for the Army. We quote

One More Rumor Scorched

Don't believe all you hear about the bad health of American youth as revealed by the medical examinations for the army. For the stories conflict and most of them are not true except for one group or some small area. Such wild reports, as that 40 per cent fail in vision tests, have led us to go to some pains to get official figures. They show the following:

It is estimated that 45 per cent of those examined are classed as "unavailable for general military service."

The major cause of rejection is dental defects, found in 18.7 per cent of those rejected. This means that just under 8.5 per cent of all those men examined have bad teeth—and no physical trouble shows any higher percentage.

The next greatest cause of rejection is eye abnormality—11.1 per cent, or about 5 per cent of all those examined.

Next in order come musculoskeletal defects, then mental and nervous diseases. Flat feet, about which you hear a lot, cannot be very prevalent, for of all the men examined less than 1.5 per cent have feet defective in any way.

So there seems to be little reason to worry about the general physical condition of our young men. Let's devote ourselves to the state of the nation instead.¹

It is a source of considerable satisfaction for physicians to know that the great number of mothers and sisters, yes and fathers, too, of the men who have been disqualified for full military duty, who read the *Woman's Home Companion*, will be correctly informed as to the facts.

It is significant that such comment as this, shorn of political considerations, divorced from the economic compulsions of the professional welfare workers' approach, is beginning to present conclusions from the facts, conclusions that are sane and well founded. We could wish for more of this sort of common-sense journalism.

¹*Woman's Home Companion* 68 No. 11, 2 (Nov.) 1941

Attention! China Calling

Early this year the JOURNAL received from Chengtu, Szechuan Province, China, a request for reprints of medical articles. Because of the difficulty in transmitting mail, second-class matter is being held up, if not permanently, at least temporarily. No publications have been received

later than May of this year in that province at least.

The JOURNAL's correspondent is Dr. Eugene Chan of the Department of Ophthalmology, Eye, Ear, Nose and Throat Hospital of the Associated Universities in Chengtu. He says (Sept. 6, 1941)

"Your reply of March 18 arrived just before I was rushed to the operating room for an emergency appendectomy. When I barely recovered from my operation, Chengtu experienced the worst air raid since the outbreak of the Chinese-Japanese War. On July 27, 108 Jap planes bombed this city. More than 2,000 civilians were killed and many wounded. We had a terribly busy time in our hospital. Part of my house was also destroyed. On Aug 11 and Aug 31 this city was again raided. The damage done by the last two raids, however, was slight. You can understand why under such circumstances I was unable to answer you earlier.

"I am very pleased to hear from you and am particularly glad to know that you are willing to copy some ophthalmologic articles and send them to me. I am certainly grateful to you for your courtesy and help. In our hospital we have a Journal Club which meets every Wednesday evening. We review and discuss all kinds of ophthalmologic subjects. Because our journals are not coming in regularly at all, we are trying to obtain reprints from various authors to supplement our journals. Furthermore, the back numbers of our journals are not complete. This is September. We have

received only the March issue of the 1941 *Archives of Ophthalmology* and the May issue of the 1941 *American Journal of Ophthalmology*."

If this is true of the special journals, it must also be true of the others. The JOURNAL suggests that the Journal Club in Chengtu should be aided in every way possible. It suggests that every ophthalmologist who reads this and who has extra reprints available, make it his business to send one to the Journal Club by first-class mail.

It is further suggested that articles other than those on ophthalmology be sent to the Journal Club as a distributing center. When any one of you reads an article in this or any other medical periodical, mark it if it is of interest to you, then, when you have read it, cut it out or have your secretary copy it on onion-skin paper if you wish to retain the original. Send this by first-class mail to

Dr Eugene Chan
E E N T Hospital
Chengtu, Szechuan
China

Here is something personal which you can do to keep the light of learning glowing in the far places of the earth. Do it consistently. Do it now!

Medical News

"Most reputable physicians," says the *Westchester Medical Bulletin*,¹ "abhor individual publicity of any kind. Unfortunately, doctors have failed to take into account the fact that in recent years medical news has become more and more interesting to the general public.

"Recently, organized medicine has become more vocal, more adept in the use of legitimate media of public information. However, as news releases

concerning general problems and scientific developments in medicine have become more and more numerous, local newspapers everywhere have become more

interested in finding local medical items of lay interest."

Out of this fact arises the delicate problem of purely local medical-press relationships. The time has long passed when this problem can be ignored or its solution be put off. Public interest in medicine is lively and legitimate. There are two angles to the lay curiosity: one, interest in medicine's scientific achievements, the other, interest in both doctors and patients as living, vital human beings, creatures of God endowed with a mixture of nobility and frailty, citizens of the community, relatives, perhaps, or friends.

How should this local problem be handled in the best interest of all? The solution does not lie certainly in a mutually antagonistic attitude

"As might be expected, local physicians everywhere individually have been far more conservative in their feelings toward publicity than their county, state, and national organizations. And, with very good reason, for in medical publicity what is sauce for the geese as a flock is not sauce for the gander as an individual. A medical society can and should actively undertake to interpret itself and its purposes to the public, but the traditional restraints upon an individual physician issuing news releases about himself are, in Westchester County at least, and elsewhere so far as we know, no less stringent than ever before.

"Hence, as local papers have begun publishing items of local news interest concerning medicine more and more frequently, the doctors involved in these news reports have become increasingly apprehensive. This has resulted in many cases in the adoption of a hang-up-the-receiver technic or slam-the-door policy on the part of individual physicians—a policy which, whatever it may have prevented, has certainly not produced more friendly relationships between the profession as a whole and the members of the fourth estate.

"Editors, naturally enough, finding their obvious sources of medical information more than unresponsive, have sometimes short-circuited the medical profession in the preparation of their news releases, resulting in the publication of many erroneous statements about medicine usually obtained from laymen or nurses or from seeking doctors of questionable reputation.

"There is much to be said for the viewpoint of the editors in this matter. They have good reason for complaint in many cases. Their job is to deliver all the news of general and local public interest. Medical news is in an important category, and the interest of the public in medical news is proved beyond cavil. If the editor of a local paper is denied the privilege of consulting the doctor concerned in a given case he can scarcely be blamed for errors in description or in choice of material. It behooves the medical profession to stand ready to pre-edit, insofar as they may have the opportunity to do so, these medical news

items. Such services can be given with the understanding that the doctor's name will not be used or, if mentioned, will not be given any unwelcome professional boost. It is completely understandable that a news item of local interest demands, in many cases at least, casual mention of well-known local medical men involved in the case. Where only one local physician is involved, however, or if the use of the name might be construed as indirect advertisement of the peculiar skill of the particular physician concerned, the physician's name should not be mentioned.

"A factor of paramount importance which should be understandable to medical men is the establishment of confidence between the newspaper man and the physician whom he is interviewing in regard to a given case. Any newspaper man worth his salt knows that he can never get anywhere in his line of work if he violates confidences, and a physician in discussing a case with a newspaper man, unless the latter is entirely unknown to him, should feel perfectly free to discuss all sides of the case if he has made it clear to the reporter just what aspects and what angles of the story must not be reported and are mentioned merely to enable the newspaperman to understand the incident as a whole.

"It should be possible to enable the members of our profession to feel more at home in their relationships with the press, in order that we may help the editors to produce medical news which is authentic as well as interesting reading. Unless we do cooperate in this manner we cannot blame the newspapers if they continue to paddle their own canoes to the best of their ability."

This is sound common sense and, we feel, an argument that cannot fail to appeal to both editors and physicians. Just as doctors in the practice of their profession must work with knives and poisons but with trained skill, so newspaper editors must use words and ideas, potentially just as dangerous as the physicians' tools in *their* business. The exact word, the correct slant to a story, is difficult to achieve in any case, it is virtually impossible where all the facts are not known. The county medical society can do much to smooth the path both for the physician and the editor.

"The Medical Society in Westchester has expressed its willingness to cooperate with the

newspapers by maintaining a clearing house for all medical news items. Such a plan both the editors and doctors feel may be of great value to the newspapers. The plan is simplicity itself. Given a lead on some medical news of potential public interest, the newspaper editor will simply call the executive office of the society and ask for verification, clarification, or elaboration of the medical facts as reported to him. The executive office will then promptly contact a reliable medical source, usually in the locality involved and within the shortest possible time will give the newspaper the information, opinion, or advice it needs or make suggestions concerning modification of the newspaper's proposed report.

"In this way the doctors involved would be freed of any personal responsibility for the part they have played in the newspaper account as it finally appears. They are free to reveal what should be revealed without the fear that what they say will be wrongfully construed by some of their confreres. Such news releases may even be published with a small by-line indicating that they have been passed by the "Medical Information Service"

of the county medical society. This plan is not a theory but a realized fact which has demonstrated its effectiveness more than once in recent months. It represents a genuine effort, and a promising one, to take some of the "bugs" out of the relationship between physicians and newspapermen and to provide a mechanism whereby the two can cooperate more effectively for the public's good.

"Whatever methods may eventually be used, it is certainly true that in Westchester, at least, a definite spirit of cooperation is developing between the press and the medical profession."

We republish this contribution to the knotty problem of medical-press relationships not as a theoretic solution but as one that has been tried and found to work. It is earnestly hoped that the plan will be given a thorough study. It goes to the heart of a matter, that is becoming of greater importance as interest in things medical continues to become more widespread.

Correspondence

To the Editor

In a recent article discussing "Physical Defects in the Genesis of Juvenile Delinquency," Blumenthal¹ highlights two important points: the effect of physical deformity in producing complexes and behavior problems, and the disquieting effect on children of parental disagreements. To be a bit classical we note that these ideas were well presented by Shakespeare.

Richard III (the hunchback) suffers from an inferiority complex and in a soliloquy bemoans his physical infirmity, thus,

"Why, love, foreswore me in my mother's womb
And, for I should not deal in her soft laws,
She did corrupt frail nature with some bribe,
To shrink mine arm up like a wither'd shrub,
To make an envious mountain on my back,
To shape my legs of an unequal size,
To disproportion me in every part,
Like to a chaos, or an unlick'd bear-whelp
That carries no impression, like the dam."

3rd *King Henry VI*, III, ii, 153

and then he vows that he will become king and embarks on a villainous role to obtain his end.

"But to command, to check, to o'erbear such
As are of better person than myself,

I'll make my heaven to dream upon the crown,
And, whiles I live, to account this world but hell,
Until my mis-shaped trunk that bears this head
Be round impaled with a glorious crown."

Ibid, 166

In order for children to develop properly both mentally and physically, one of the most important requirements is a congenial home environment. This essentially means pleasant and agreeable parental relationship. Any discord between husband and wife is of necessity reflected in the health and happiness of the children. One can only surmise the myriad mental aberrations that obtain in the unfortunate children of divorced parents. Shakespeare depicts the effect of parental disagreements on a child. Leonates who is unjustly jealous of his wife maltreats her. This home maladjustment weighs heavily on their only son, thus,

"He straight declined, droop'd, took it deeply,
Fasten'd and fix'd the shame on 't in himself,
Threw off his spirit, his appetite, his sleep,
And downright languish'd."

Symposium on the Surgical Treatment of Goiter

GOITER—INDICATIONS FOR OPERATION

How to Differentiate Toxic Goiter from Conditions Simulating It

G W CORRIS, M D, Jamestown, New York

A GENERATION ago, hyperthyroidism without exophthalmos was often unrecognized by physicians. When it was recognized it was treated medically more often than surgically. Operative mortality was high, while the mortality of the disease itself was assumed to be low. Forchheimer in his *System of Therapeutics* said "In my whole experience I have seen only 1 death from this disease and that was due to thyroid feedings." At every medical convention there was a battle royal between surgeons and medical men over the question of whether hyperthyroidism and appendicitis were surgical or medical diseases.

The surgeons won the contest for appendicitis long before they could prove their claim to superior results in the treatment of hyperthyroidism. As the technic of thyroidectomy became standardized, operative mortality was lowered, while the high morbidity and the final high mortality caused by cardiac damage in long-standing cases became more widely appreciated.

The parallelism of thyroid and appendix disease still continues. While it is still true that in both cases the surgeon receives many patients too late, the public is threatened not so much by delayed operations as by operations that are not justified. For that reason it seems worthwhile to consider the diseases that simulate hyperthyroidism before discussing the indications for operation.

Last year Dr. Noehren reported an analysis of 185 cases referred to him with a mistaken diagnosis of goiter. His findings were in accord with the experience of all thyroid surgeons. About two-thirds of the mistaken diagnoses came under the head of anxiety and other neuroses and neurocirculatory asthenia. Organic heart disease and essential hypertension accounted for most of the remainder.

Mild forms of depression which occur in both men and women between the ages of 40 and 60 constitute a danger against which we must always be on guard. If agitation is an accompaniment of the depression, the basal

metabolic rate may rise to +30. The tremor, nervousness, and emotional disturbances are suggestive of hyperthyroidism. If a patient with this syndrome does not improve under iodine treatment, testosterone in men and theelin in women will often act as specifics. Improvement or apparent cure under such treatment is a positive contraindication to thyroidectomy, even though a thyroid adenoma is present. Operation makes these patients worse, and in some cases suicides have followed within a few months after such mistakes have been made.

Without attempting to classify the neuroses, we may say that the broad picture is one of nervousness, weakness, tachycardia, emotional disturbances, tremors, and either loss of weight or constant underweight. When the sensation of choking (globus hystericus) is added to this picture, it is not surprising that many of these patients come to the surgeon for thyroidectomy. Unfortunately, once the suggestion of goiter has been made, they are eager for operation and are, therefore, easy prey for incompetent or dishonest practitioners. To a commercially minded surgeon they must be irresistible.

In most cases differential diagnosis is not difficult if the following points are kept in mind.

In hyperthyroidism some degree of thyroid enlargement is always present, although sometimes its detection requires skillful palpation.

Thyroid tachycardia is constant, in neurosis it subsides under rest alone.

The skin of thyroid patients is warm and moist, and flushing of the neck and chest frequently appears during the examination, in neurotic patients the hands and feet are usually cold and clammy.

In thyroidism loss of weight occurs in spite of a good appetite, in neurosis the appetite is usually poor.

Patients with hyperthyroidism are usually intolerant of heat. Neurotics are either cold or alternate between sensations of heat and of cold.

The therapeutic test by iodine administration is of value. Few cases of hyperthyroid-

ism fail to show improvement and these are always cases of toxic adenoma where the nodular goiter is easily palpable

Exophthalmos and increased basal metabolic rate point strongly to hyperthyroidism, but neither of them is a positive proof of its existence and their absence, of course, does not disprove it

We must be especially on our guard now that the real World War is getting under way. In the last war, anxiety neuroses were common in the Army. When our public finally awakes to the implications of the present situation, these neuroses will become as common among civilians as they were among our soldiers in the lesser war of 1918.

Time does not permit discussion of organic heart disease and hypertension. Any proper examination should lead to their discovery.

We come now to the indications for thyroid operations. We need waste no time on cases of fully developed hyperthyroidism whether due to toxic adenomas or diffuse hyperplasia or to large nontoxic goiters producing pressure symptoms. In these patients the indication for surgical treatment is no longer debatable.

Difficulty in deciding whether or not to operate arises most often in two classes of cases. First are those patients with slight thyroid enlargement and mildly toxic symptoms. It seems reasonable to believe that many of these patients suffer from functional rather than organic hyperthyroidism. There is often a background of domestic or financial troubles. With correction of the psychic factor, rest, and medication with small doses of iodine and sedatives many of them can be cured without operation. It is true that recurrences are not infrequent, but even when they do occur the patient usually responds again to treatment.

If she is found to be iodine-resistant, operation is indicated before the thyrotoxicosis becomes too great for safe surgical intervention.

The second group comprises older patients with long-standing heart disease whether caused or complicated by toxic hyperplasia, toxic adenoma, or large nontoxic goiter. In these cases fibrillation is often present, and decompensation is shown by edema, dyspnea, and cyanosis. They are obviously poor surgical risks. Nevertheless, some of these bad risk cases, even though the thyroid factor seems debatable, in my experience have yielded the most brilliant results. Whether it is the toxic effect or the added load on the heart caused by pressure is difficult to say. The fact remains that many cardiac patients who are bedridden, who are no longer responding to any medical treatment, and whose fibrillation is constant and refractory may be restored to usefulness by a carefully performed thyroidectomy, carried out in one or more stages as indicated by the reactions observed during the operation.

One other group worth mentioning because it is not generally referred to in textbooks is that of paroxysmal tachycardia. They are not often seen but, when recognized, operation gives dramatic results. We have had about 6 such cases. None of them were extremely toxic, and the first case had no toxic symptoms whatever. In all of them an adenoma of the left lower pole extended well into the thorax, and in all of them the attacks were permanently eliminated. Whether they were due to mechanical irritation of the vagus, as I suspect, or to intermittent hyperactivity of the adenoma, which I doubt, the fact remains that in every case of paroxysmal tachycardia this etiology is worth considering.

THE PREOPERATIVE AND POSTOPERATIVE USE OF IODINE IN HYPERTHYROIDISM

T B JONES, M D, Rochester, New York

THE subject of the use of iodine in hyperthyroidism may appear hackneyed to many and unworthy of further discussion. However, a few points may be reviewed at this time, in addition to calling attention to some clinical

experiences that possibly have not been sufficiently emphasized.

In the past there has been some difference of opinion as to the response to iodine obtained in the various forms of hyperthyroidism. Clinical experience has established the fact that iodine is as effective in secondary hyperthyroidism (toxic nodular or adenomatous goiter) as it is in primary hyper-

FIG 1

thyroidism (exophthalmic goiter) The majority of cases of toxic goiter seen in our clinic are of the nodular type. It has been our observation that they react to iodine in the same way, and to the same degree, as do the cases

of diffuse toxic or exophthalmic goiter. We feel that there is no essential difference between the two types of cases and that the differences in symptoms commonly seen are often attributable to the differences in ages at which the disease develops.

Lugol's solution is the most popular iodine preparation used, although other compounds such as potassium or sodium iodide have been shown to be equally effective in producing a remission. That the usual doses given, 10 to 30 minims daily, are far in excess of the amount of iodine required to produce a remission has been shown by Thompson, *et al*, who secured a satisfactory response using 1 minim of compound solution of iodine by mouth daily.¹ The greater part of the iodine given in these larger doses is lost to the body by excretion in the urine. It is not known whether iodine in the circulation, other than that bound by the thyroid, exerts any beneficial effect on the toxic symptoms. It has been suggested that under these circumstances a temporary absorption by the thyroid gland may occur with some benefit.² In our experience we have

FIG 2

never noted any untoward symptoms from the use of excessively large amounts of iodine other than the development of a rash, an occasional instance of pain in the jaw, and salivation. We have never seen the deleterious effects described by Barker,³ although we have given daily as much as 1 to 3 Gm. of sodium iodide intravenously over a period of several days in some cases. Since there may be some virtue in supplying an excess of iodine, it would appear advisable to continue using the larger doses.

Brief references have appeared in the literature regarding the use of iodine intravenously, but such parenteral administration has not received the emphasis it deserves. In a previous communication⁴ we reported some of our experiences with large doses of sodium iodide given intravenously and, while intravenous iodine is not advocated as a routine procedure, certain observations and advantages might be re-emphasized. We found that in the majority of cases of hyperthyroidism a satisfactory iodine remission could be obtained within a period of three to four days by giving a total of 30 Gm. of sodium iodide intravenously.

Within this period of time subjective improvement was often noted by the patient. Objectively, there was also improvement, the basal metabolic rate decreasing an average of 54.5 per cent. Twenty cases so treated are shown in Chart I. It will be seen that the cases are representative as to age, type, and degree of toxicity. Furthermore, the remission in most instances was complete, additional iodine failing to produce any further decrease in the basal metabolic rate (Fig. 1). It would appear from these observations that excessive amounts of iodine intravenously are of some value when a rapid remission and decrease in toxicity are necessary.

It should be emphasized that intravenous iodine, with the attendant rapid response, is not advocated to the exclusion of the usual preoperative preparation of rest in bed and other general medical measures. Rather is it suggested that by obtaining such a rapid iodine response quickly and early in the course of treatment one can expect greater benefit from the other forms of preoperative treatment.

This method of iodine administration also

seemed to be of value in some cases that were refractory to oral administration. We often obtained a satisfactory response in these patients, although on the average the improvement was not so marked as in the cases mentioned above. However, the possibilities of intravenous administration should be borne in mind when one is treating a patient who appears to be "iodine-fast."

We have seen a number of patients in an impending or a fully developed "thyroid storm" and, while it is extremely difficult to evaluate accurately each therapeutic measure used, we have the distinct impression that the repeated intravenous administration of sodium iodide in such patients has been responsible for overcoming this most disastrous of all thyroid complications in many instances. We have given 10 Gm. of sodium iodide as often as three times per day and have observed no ill effects. In the patient whose course is shown in Fig. 2, a maximum dose of 10 Gm. per day was used. This patient appeared to be "iodine-fast," since there was no diminution in the basal metabolic rate after thirteen days of Lugol's solution by mouth. In fact, on the thirteenth day it appeared that a "storm" was impending, and on the fourteenth day it was obviously fully developed. By the time 30 Gm. of sodium iodide had been given intravenously the patient was out of coma and obviously improving clinically, although the improvement was not immediately apparent on her chart. Her recovery continued satisfactorily thereafter.

Since using this type of treatment, we have been more successful in handling such cases

than formerly. Since other therapeutic measures employed were essentially the same, it would seem reasonable to attribute any improvements in results to the iodine given. We urge its use in such cases, particularly as no untoward effects have been observed.

The question of how long after operation iodine should be continued is, as far as I know, a matter of conjecture and personal opinion. We usually gave small amounts, 2 to 5 minims, of Lugol's solution per day during the period of hospitalization. It has been our custom to continue iodine, 1 minim per day, over a period of some two months. The only rationale for its use is the observation of Halsted that the administration of small amounts of iodine in dogs prevented regeneration of normal thyroid tissue remaining after subtotal resection of the gland. Whether or not it prevents the regeneration of hyperplastic thyroid tissue is not known.

Any discussion of iodine therapy would not be complete without emphasizing the point that the surgeon should be given the opportunity to examine the patient before iodine is given. One cannot accurately appraise the severity of the toxicity after a remission has been obtained, and a surgeon seeing a patient for the first time under such circumstances is at a distinct disadvantage.

THYROIDECTOMY—TECHNIC

FREDERICK S. WETHERELL, M.D., Syracuse, New York

THE prime requisite of any surgical technic is safety. In no operative procedure is this more important than in that of thyroidectomy. Two most important pitfalls are to be avoided: viz., injury to recurrent laryngeal nerves and hemorrhage. Hemorrhage may be immediate, at the time of operation, or later—after the patient has returned to his room. Another factor to be considered is the amount

of tissue removed during the operation, a consideration that is rather empiric yet demands clean-cut surgery lest only a shaving-off result ensues.

Every surgeon develops a technic that fits his abilities, without question this is always a combination of methods that have been taught since Kocher's time. It would, therefore, be impertinent for anyone to say that this or that complete technic was entirely of his own devising. It is, however, equally true that small portions of a technic, elaborated by an individual by trial-and-error methods, may

never noted any untoward symptoms from the use of excessively large amounts of iodine other than the development of a rash, an occasional instance of pain in the jaw, and salivation. We have never seen the deleterious effects described by Barker,³ although we have given daily as much as 1 to 3 Gm. of sodium iodide intravenously over a period of several days in some cases. Since there may be some virtue in supplying an excess of iodine, it would appear advisable to continue using the larger doses.

Brief references have appeared in the literature regarding the use of iodine intravenously, but such parenteral administration has not received the emphasis it deserves. In a previous communication⁴ we reported some of our experiences with large doses of sodium iodide given intravenously and, while intravenous iodine is not advocated as a routine procedure, certain observations and advantages might be re-emphasized. We found that in the majority of cases of hyperthyroidism a satisfactory iodine remission could be obtained within a period of three to four days by giving a total of 30 Gm. of sodium iodide intravenously.

Within this period of time subjective improvement was often noted by the patient. Objectively, there was also improvement, the basal metabolic rate decreasing an average of 54.5 per cent. Twenty cases so treated are shown in Chart I. It will be seen that the cases are representative as to age, type, and degree of toxicity. Furthermore, the remission in most instances was complete, additional iodine failing to produce any further decrease in the basal metabolic rate (Fig 1). It would appear from these observations that excessive amounts of iodine intravenously are of some value when a rapid remission and decrease in toxicity are necessary.

It should be emphasized that intravenous iodine, with the attendant rapid response, is not advocated to the exclusion of the usual preoperative preparation of rest in bed and other general medical measures. Rather is it suggested that by obtaining such a rapid iodine response quickly and early in the course of treatment one can expect greater benefit from the other forms of preoperative treatment.

This method of iodine administration also

lateral side of the gland than have been injured by delivering the gland much as E. P. Sloan said, the head is delivered by a pair of low forceps. There is no particular pull or tension exerted on the nerve by this maneuver. The right hand holds the forceps previously mentioned, and another, placed at the junction of the lower and middle thirds of the lobe, exerting a pull toward the midline while the finger tips of the left hand gradually work behind the gland toward the trachea. The posterior surface of the gland may then be seen and, what is more important, felt. It is at this point that the technic here described differs from those that I have seen—from this point on the sense of touch of the left hand directs the lobectomy. Both holding-forceps—more if necessary—can be held between the thumb and index finger while the remaining fingers are behind the gland. This maneuver not only detects nodules, which may be either adenomas or parathyroid glands, but it also gives evidence of the absence of the threadlike recurrent laryngeal nerve. It must be remembered that the sense of touch is much more accurate than sight when it comes to identifying deep lying nerves. Those who have operated on trunks of the sympathetic nervous system, or on the phrenic nerve, will readily testify to this fact, once having found how much simpler it is to feel first and see afterward. A fine piece of silk laid along the posterior surface of the gland will prove this to the doubter. Having determined that the fingers are as far medially as it is possible to go behind the gland, hemostats are then placed in a lateralward direction, from upper lobe downward to isthmus, biting into isthmus (thus leaving only small tufts of it on the tracheal surface) and encircling the lower pole. The hemostats along the lower pole are placed so that the tips point superficially, this is an added safeguard against injury to the recurrent laryngeal nerve. To point them backward during application is dangerous from this point of view. As each clamp is placed the tissue is cut with a knife. With practice, as much or as little may be left as is desired, the tips of the fingers behind being the guide to the forceps in front. In other words, this is largely a sense-of-touch technic. In this manner one may safely skim closer to the posterior envelope than it is possible to do by any sight method. Having completed the dissection on one side, all points are ligated with No. 00 chromic catgut. I have a so-called catgut detail man to thank for my having changed to a fine chromic catgut. Being assured by

him that this suture would practically eliminate the serum found so often when plain catgut is used and finding silk not so easy to handle as catgut, I have been agreeably surprised to find that the chromic suture equals the silk with respect to the lack of postoperative serum.

Superior Thyroid Arteries

These arteries are now handled by placing around them, on a round pointed needle, a suture of No. 00 chromic catgut, doubled, and tied once above the upper superior pole clamp and then, having thrown both clamps upward, tied below them, removing both clamps after the first lower knot is tied. This suture is then carried downward, closing over the surface of the gland. This suture not only doubly insures hemostasis but it also destroys tissue caught in its succeeding bights—of no little value in an extremely hyperplastic gland. The suture is run down the gland remnant and then back up again, and the two ends are tied onto the superior thyroid artery. When placing the needle under the superior pole, the fingers of the left hand press back the main vessels of the neck. The opposite lobe is dealt with in the same manner, assuring hemostasis.

At this point the anesthetist (employing cyclopropane anesthesia in most cases) allows the patient to "come out," cough, speak, gag, and in any way possible induce an increase in intrathoracic pressure, the purpose, of course, being to uncover potential bleeders. Saline solution, always at hand in case inadvertent damage to a vein requires its being poured into the wound to avoid an air embolism, is now poured into the wound to wash out clots that might later blow out. Hemostasis having thus been assured, the muscles are brought together.

Muscle Suture

After the upper portion of the sternohyoid has been brought together with No. 00 chromic catgut, the midportion of this muscle is lifted, and the sternothyroid muscle is pulled forward from the laterally receded position it has assumed. This is an important step in that this muscle, brought back to the midline, covers the trachea and prevents the swallowing-tug due to adherence of the trachea to the more superficial tissues.

Drainage

Four strands of silk are now laid across the wound, a split-shot is clamped on either end

perhaps be claimed as his contribution to the general advancement of surgery. With this understanding the following method of thyroidectomy is here presented, with reasons for each step described.

The Skin Incision

This is made with a firm sweep of the knife which carries down to the superficial layer of the deep fascia of the neck. It is made somewhat more than two fingers breadth above the suprasternal notch, determined by laying the middle finger along the upper border of the notch with the index finger above it. The incision goes straight across rather than forming a downward convexity as was formerly, and still is, practiced by some. In thyroidectomy the head is usually tilted backward, thus, if the incision is not made higher than usually seems proper, an unsightly scar running across the upper border of the clavicles results. The scar is the only thing about which the patient may brag after the operation, and surgeons have been known to admire a hair-line scarcely visible at three feet.

Reflecting the Skin

Having reached the proper plane, that between the superficial fascia and the superficial layer of the deep fascia, one need but begin the skin reflection with the knife. It is then possible to push back both the upper and lower flaps with a piece of gauze over the index finger of the dissecting hand, a thumb forceps holding the flap as it is separated from the underlying deep fascia. There is a distinct advantage in this maneuver in that small hemorrhages are avoided inasmuch as the large veins lie deep to the deep fascia, while the many small vessels in the superficial fascia seldom communicate with the deeper ones. We therefore have a practically hemorrhage-free plane if we start the dissection properly. This is a time-saving technic.

Opening the Neck

With Robert Emmett Farr spring retractors in place, the deep fascia and underlying pretracheal muscles are separated in the medial line, longitudinally, of course, and avoiding the anterior jugular veins. Having reached the surface of the gland, the index fingers of the operator and first assistant are placed underneath the muscles and the neck is opened in the same manner as the peritoneum is opened in an abdominal incision—viz., by lifting toward the ceiling, thus avoiding injury to underlying structures. With care it is often possible

to note the presence of the communicating branch between the two anterior jugular veins at the level of the suprasternal notch. This is an inconstant vein yet, if seen, should be tied immediately. This incision should never be skimped. Room makes for better surgery.

Cleaning Surface of Lobe

The handle of the knife is now insinuated between the surface of the lobe and the sternothyroid muscle and the muscle is freed from the gland. A fenestrated, curved retractor is placed under the upper angle of the muscles and held by the second assistant on the operator's left. This maneuver should partially expose the superior pole. It is at this point that I have seen the beginning of a sloppy thyroidectomy caused by the failure to recognize the presence of muscle fibers of the sternothyroid still sticking to the gland. This has prevented visualization of the gland surface, so many technics still depend on visualization—a matter to be taken up later. It is at this point, therefore, that the operator must make certain that no muscle fibers remain on the gland, a condition so frequently observed when thyroiditis has been present. The fibers are easily scraped off the gland with the edge of the knife, being then caught up by the retractor with the rest of the muscle bundle.

Middle Thyroid Veins

At this point of the dissection it is likely that veins may be seen coursing laterally from the midportion of the lobe. These are to be double clamped and tied at once, for, if torn, a troublesome hemorrhage and time-consuming hemostatic effort ensue. It is well to care for these veins immediately at any time that they are seen.

Delivery of Lobe

After being certain that muscle and often areolar tissue (particularly on the lower portion of the lobe) have been cleaned off, the gland is grasped by its upper third with a pair of toothed forceps with a lock handle (there are several varieties) which do not tear through the gland tissue. A downward pull is made to expose the superior pole and two Stille-hemostats are applied, crushing the uppermost portion of the pole between them. The knife then cuts through the pole below the lowermost clamp and, thus, the lobe is made ready for delivery. It has been my feeling for a long time that more recurrent laryngeal nerves are damaged by blindly, or without sense of touch, placing clamps from either the medial or

rule The entire upper pole of the gland should be exposed by reason of the fact that there are frequently several branches of the artery and vein supplying the upper pole Seven such vessels were found in 1 case In bad risk cases that react seriously, a second ligation is safer These very seriously ill patients are best sent to their homes for two to four months' rest in bed and general care before undertaking even unilateral excision

With patients apparently in not so serious a condition, the regular collar incision may be made If alarming symptoms develop, the superior thyroid artery may be ligated under the flap and three or four temporary sutures inserted If postoperative progress is satisfactory, it is sometimes possible to reopen the wound and to go on with the unilateral excision within five or ten days Rarely is it possible to do a partial bilateral excision When the condition is so serious as to demand unilateral excision, excision of the remaining lobe may be undertaken from three to six months later, depending on the rapidity and degree of improvement At almost any stage in the operation if alarming symptoms develop, operation should not be continued further, but closure should be made with temporary stitches inserted The incision is usually best reopened in from five to ten days, the edges of the flap trimmed and a careful

closure carried out with sutures of the platysma muscle, and careful skin closure done for which we usually use fine black silk In cases of the worst possible risks we have ligated each superior thyroid artery at separate operations at an interval of a week through direct incision (first and second stages), then we have undertaken the excision of one lobe with temporary closure (third stage), and a second trip to the operating room is made to trim the flaps and make a satisfactory permanent closure (fourth stage) The second unilateral excision (fifth stage) almost always has to follow, with another secondary closure (sixth stage)

The patients requiring such intervention are those having extreme toxemia, a badly damaged heart, extremely high blood pressure, in a few instances, extremely large or deeply located goiters, particularly those in which the rings of the trachea have been softened by prolonged pressure so that there is great difficulty in breathing, and, occasionally, in case of malignancy.

In conclusion, with desperate risk goiters (1) do the least possible surgery that offers the patient benefit, (2) make the operating time short, but not at the sacrifice of accuracy and gentle manipulation, and (3) avoid long and extensive procedures—this is highly important

ANESTHESIA IN GOITER SURGERY

OSCAR HAYEN STOVER, M D , Buffalo, New York

NOT so many years ago the choice of a general anesthetic for any particular procedure was rather an easy one It was easy because there was so little choice The patient was, so to speak, molded to fit the anesthetic pattern Today, with a wide choice of general anesthetic agents and the help of various premedicants, the anesthetic is planned so as to suit the patient's pathology The statement that, "one uses this, or that, anesthetic routinely," seems to me to be as much out of our past as is the horse and buggy

Only a few years ago it was the surgeon who, alone, made whatever choice was made in regard to anesthetics Today, due to the development of the science of anesthesiology and, along with it, a trained personnel of

anesthesiologists almost everywhere available, this situation has changed Surgeon and anesthetist together decide on the type of anesthetic most suitable for the patient However, it must be borne in mind that a patient is only having an anesthetic because he must for some reason be operated upon The anesthetic, therefore, must be one that permits the surgeon to do the necessary surgery with the greatest possible ease. On the other hand, the anesthetic must accomplish this with the least amount of physiologic upset to the patient To bring about this balance between the patient on the one hand and the necessary surgical procedure on the other hand is often difficult Sacrificing of operative convenience may be necessary for the immediate good of the patient No operation, or no anesthetic either for that matter, is successful unless the patient lives

(Roeder, C. A.), and the skin is approximated with small Michel clips

The drainage strands are removed at the end of twenty-four hours, the clips, on the third postoperative day

The foregoing describes a typical thyroidec-tomy without complications. It is a safe technic in my hands. There are, of course, exigencies in which it must be altered. For example, a large gland might demand that the prethyroid muscles be cut transversely, there should never be any hesitancy about doing this. Plenty of room—as much room as possible—is demanded in any operation in which danger constantly lurks

The technic of handling intrathoracic goiters is not gone into, this being a subject by itself. "For thrills in surgery," says André Crotti, "limit your work to the removal of intra-thoracic goiters"

Neither has this discussion taken up the matter of the amount of gland substance to be

removed, that is a matter of judgment which can be acquired by practice and reading. There can be no excuse, however, for merely shaving off the surface of the gland and leaving three-fourths of a lobe behind. Thyroidec-tomy at its best is but a crude method for the treatment of goiter, but it does require of those who attempt it that they perfect themselves in technic

To the following, whose work I have observed over a long period of years, who have always been an inspiration to me, and who have made it possible that the foregoing was written at all, go my thanks

Pemberton (hemostatic suture), Crotti (time-saving methods), Sloan (delivery of gland), Dinsmore (forward-pointing clamps at lower pole), Arnold Jackson (handy saline), Crile (nicety of technic), and to many others whose additions rest in one's subconscious mind yet direct the fingers when the need arises

MANY-STAGE OPERATION FOR GOITER

MARTIN B. TINKER, M.D., F.A.C.S., and MARTIN B. TINKER, JR., M.D.,
Ithaca, New York

ALL surgeons familiar with the care of a desperate risk goiter cases realize that operation, even after considerable preliminary care and medication, is attended by almost prohibitive risk. It is generally conceded that all desperate patients usually should be kept on preliminary rest and care for weeks or, in some instances, months before attempting even slight surgical intervention. Kocher, of Bern, reduced this risk by preliminary ligation many years ago. At a meeting of the Section on Surgery of the American Medical Association in 1912, one of us (M. B. T.) proposed the many-stage operation, adding to ligation the unilateral excision of one lobe, packing the wound temporarily, and making a secondary closure—this procedure being followed on both sides if necessary. Fortunately, it is not essential that all be finished at one stage as in many operations of major surgery. Reduction to a minimum of time on the operating table makes it possible to operate successfully in some apparently inoperable cases

This reduces the mortality to a fraction of 1 per cent and gives satisfactory permanent results for a number of such patients

The number of short operative stages we have used has been as many as six in certain extremely bad cases, some of these patients were admitted to the hospital on three different occasions. One patient whose basal metabolic rate could not be taken lower than +120 is now in relatively good health and working his farm near Ithaca. The laboratory tests were made under the supervision of Dr. Barton Hauenstein, now teaching at Buffalo University Medical College. Another patient with a serious heart lesion, and almost as toxic, has been in fairly good health for over a year and bids fair to improve still further. The combination of stages varies under different conditions

Kocher's ligation of the superior pole through incision directly over the artery is the simplest and safest procedure. A triangle is formed with the base upward by the hyoid bone above, the sternomastoid behind, and the sternohyoid muscle in front. The sternomastoid has to be retracted backward as a

vantage of being controllable with regard to the depth of the anesthesia. Sometimes, when the surgeon works close to the recurrent laryngeal nerve, the anesthesia is lightened and the patient becomes conscious and is made to talk. This gives some indication as to whether there has been any injury to the nerve (Noehren⁴). After this test is made the patient is again carried to a deeper level of anesthesia. On awakening, the patient has no recollection of this test. Nitrous oxide-oxygen is also nonexplosive, and this is a factor where electrosurgery is to be carried out. It must not be forgotten, however, that addition of any ether to this mixture makes it explosive. With this anesthetic patients recover quickly and there is less nausea than with any other general inhalation anesthetic.

The chief disadvantage of nitrous oxide is the fact that it is given with a low percentage of oxygen. This anesthetic is often, though not always, associated with an anoxemia in varying degrees. The anoxemia is theoretically more dangerous than it is practically more dangerous. This is definitely borne out by the thousands of these anesthetics administered each year without difficulty. Because we have a choice, I believe that thyrocardiac patients, thyroid patients with obstruction, or patients suffering from any cardiac decompensation should be given general inhalation anesthetics where anesthesia is associated with higher oxygen concentration, contraindicating the use of nitrous oxide-oxygen.

Ethylene is an excellent anesthetic for thyroid surgery. It has a rapid induction and a short recovery period. It is given with considerable oxygen and ordinarily there is no associated anoxemia. Postoperative nausea is greater than with nitrous oxide, and the anesthesia produced is satisfactory. Mixtures of ethylene with oxygen or air are explosive, and this should be kept in mind, making its use contraindicated where electrosurgery is contemplated. Because I believe that there is nothing that ethylene will do that cyclopropane will not do better, I have not had occasion to use ethylene for quite some time.

Cyclopropane is my choice of a general inhalation anesthetic in thyroid surgery where a high oxygen concentration is beneficial to the patient. Because the administration of cyclopropane is so satisfactory from the anesthesiologist's personal point of view, I feel that we many times use it when nitrous oxide would be of advantage. The high concentration of oxygen, the extreme controllability, the rapid

induction, the short wakening time and, usually, the satisfactory type of anesthesia are the outstanding advantages of cyclopropane. In thyroid patients suffering from dyspnea due to obstruction, the high oxygen concentration is of definite value. Many of these patients who have a poor color before the anesthetic will have an excellent color under the anesthetic. The anesthesia can also be carried to a sufficiently deep plane so that an intratracheal catheter may be passed should the occasion arise.

I do not believe in the routine use of intratracheal catheters in cases of tracheal obstruction or suspected obstruction. The passing of the intratracheal tube is not without danger, and the patient should not needlessly be subjected to this extra risk. The dangers are physical trauma, associated with the passage of the tube, and also the introduction of infection from the nose or pharynx directly into the trachea. It is well always to remember the fact that where cyclopropane or any other combustible anesthetic is used the use of electrically lighted instruments in the oral cavity is not without risk. Five anesthetic combustions, resulting in the death of 1 patient and a serious injury to another, have recently been reported (Greene⁶). A laryngoscope and appropriate catheters, etc., should, however, be immediately available should the necessity for their use arise. I have administered anesthetics to more than 1,000 consecutive thyroid cases of Dr. Noehren's without using intratracheal intubation.

Ordinarily, thyrocardiac patients do well under cyclopropane anesthesia but, occasionally, auricular fibrillation will take place. This can sometimes be controlled by lightening the plane of anesthesia, but, if this is not possible, the anesthetic plan can be changed and the patient switched to nitrous oxide-oxygen, with or without adding ether. The disadvantages of cyclopropane in thyroid surgery are the occasional association of auricular fibrillation, the increased postoperative nausea as compared to nitrous oxide, and its explosiveness. The explosion range of cyclopropane can be materially shortened, if not altogether eliminated, by the proper use of helium in the anesthetic mixture (Jones and Thomas⁷).

Some advocate the use of *acertin* in thyroid surgery, particularly in the toxic thyroid patients. Here, however, it is not used as an anesthetic but as a powerful hypnotic, it being necessary to administer an anesthetic to the patient prior to his being operated upon. It is true that because the patient goes

In no other operative field is the full co-operation of surgeon and anesthetist more necessary than in that of thyroid surgery. This cooperation should not be one for merely the time that the patient is on the operating table. It should be a cooperative venture from the beginning of hospitalization until the patient is well along in convalescence. It is true that in nontoxic goiters without obstructive symptoms the anesthetic is no particular problem. However, as the surgeon gains experience through seeing many cases so, too, does the anesthetist. The value of the judgment of the anesthetist is also in direct proportion to the number of thyroid cases of all kinds which he has an opportunity to see and study. The anesthetist's duty is not merely to keep the patient alive during the period that he is in surgery, for this is only shortsightedness, but his judgment must be influenced not only by events of the present but by reactions that may follow postoperatively. He must be so familiar with the patient that should unfavorable signs develop during the course of the anesthetic he will recognize them as such and suggest termination of the operation, or, perhaps not even start it. In order that the anesthetist's judgment be tempered by experience, he must note the postoperative response of all of his thyroid cases.

With regard to thyroid anesthetic agents, the literature gives ample evidence of the fact that ether, nitrous oxide, ethylene, cyclopropane, avertin, various types of local anesthesia, and combinations of local and general have all been successfully used in thyroid surgery. Each of these agents have advantages and disadvantages over each of the others. The choice of an anesthetic should be on a pharmacologic basis in an attempt to adjust the anesthetic to the patient's pathology and the operative procedure contemplated.

A good anesthetic presupposes proper preanesthetic medication and preanesthetic treatment. First and foremost is a personal contact between patient and anesthetist. The patient must have confidence in the person who is to put her to sleep. Much of the patient's fear of the operation is, in reality, fear of the anesthetic. Good anesthetist-patient relationship does much to minimize this fear.

Sedatives are often given thyroid patients from the beginning of their hospitalization but should always be given in fairly good doses the evening before the operation and the following morning. Such drugs as phenobarbital, sodium amytal, nembutal, and sodium bromide are useful in proper dosage. Where

barbiturates are not tolerated a bromide preparation may be used. There are those who use paraldehyde as a hypnotic. Its use may increase the incidence of pneumonia (Crile and Adams¹), due to the fact that it is largely excreted through the lungs. Besides, I believe a hypodermic of morphine sulfate and atropine sulfate about forty minutes prior to the operation should be used. Morphine further depresses metabolism, and atropine dries the secretion of mucus and saliva. Scopolamine may be substituted for atropine but may cause unpleasant cerebral stimulation. Oversedation may mask inherent toxicity (Cole and Brunner²). This is another reason why the anesthetist must be familiar with the patient.

Thyroid surgery is best performed early in the morning, particularly in the toxic patient, obviating the necessity of a long period of waiting. The patient's room should be dark and quiet so that the mental state will be as calm as possible. The trip to the operating room should be made quickly, with the eyes covered with a loose fitting towel. A portable operating table taken to the patient's room necessitates only one move from bed to table. On arriving in surgery there should be no delays, and the patient should immediately be taken into the operating room and the anesthetic started at once. Operating room and personnel should be absolutely quiet until patient has lost consciousness.

Ether, alone, has no place in modern thyroid anesthesia where other anesthetics are available. It is irritating to the mucous membrane of the trachea, and its use increases the incidence of tracheitis following thyroidectomy. Ether has a too long and unpleasant stage of induction adding to the psychic trauma of the patient. Small amounts of ether are sometimes used without deleterious effect with nitrous oxide, ethylene, and cyclopropane to bring the patient to a suitable stage of anesthesia. It has been shown (Rosenthal and Bourne³) that ether produces a mild, transient impairment of liver function. Where used in small amounts, however, this is not a factor. Where an anesthetic is to be administered by inexperienced hands, however, ether is the choice.

Nitrous oxide-oxygen is an excellent anesthetic for thyroid patients. Inasmuch, as these patients are ordinarily well premedicated and since the operation requires no great amount of relaxation, nitrous oxide is usually sufficient unto itself. Small amounts of ether may be added without harm. It has the ad-

attention to every detail, especially toward the prevention of complications

Formerly, many patients died from so-called thyroid crisis, today, this alarming condition is only rarely seen and then usually in patients who have been the unfortunate victims of an attempt to cure hyperthyroidism by the administration of iodine. Such patients demand the utmost skill and attention to ensure a successful result. Prolonged preoperative treatment—including bed rest, a high calorie diet, a high fluid intake, vitamin preparations, and suitable sedatives—is an important general measure. Compound solution of iodine is the specific preoperative treatment of choice and is preferably given by mouth. Intravenous sodium iodide is helpful in the preparation of difficult cases. Reassurance and psychotherapy are important aids in overcoming fear and apprehension. Prevention of infections of the upper part of the respiratory tract and proper attention to oral hygiene are beneficial. The fluid intake may be easily supplemented by intravenous glucose and, in selected cases, by blood transfusion.

The selection of the type of operation, single- or multiple-stage, is most important to these critically ill patients. The decision should be based upon the condition of the patient at the time of admission to the hospital and should rarely be changed by the improvement achieved by preoperative care. The use of multiple-stage operations has indeed been a factor in lowering the mortality from thyroid surgery, but in our experience less than 5 per cent of the cases actually demand this type of operative procedure. In spite of this low incidence of two-stage thyroidectomies our mortality rate has been 0.85 per cent. We feel that a more careful study of each patient, together with better preoperative care, has enabled us to attain this result without too frequently resorting to multiple operations.

The most valuable postoperative therapeutic agents are morphine and intravenous glucose. Coller and his associate¹ have amply demonstrated the enormous fluid requirement of patients with hyperthyroidism and, when the throat is sore and swallowing difficult, intravenous administration of glucose solutions is the most satisfactory way of maintaining an adequate fluid intake. A few cases may require the addition of blood transfusion. Morphine in doses large enough to relieve pain and prevent restlessness is as important as proper fluid intake. It should be

remembered that hyperthyroidism increases the tolerance to morphine, and larger or more frequent doses are required to produce a full effect. Patients with a psychosis may respond better to a paraldehyde than to morphine.

Oxygen therapy has been proved a valuable aid in the treatment of the critically ill thyroid patient. Since hyperthyroidism greatly increases the need for oxygen and since anoxia cannot be detected in its early stages, we feel that the postoperative administration of this agent should be made a routine procedure for all bad risk patients.

Ice, either as individual ice caps or as an ice pack, may be necessary to control the extreme hyperthermia that is sometimes seen. Acetyl salicylic acid is also helpful in reducing fever.

In our experience, iodine therapy in the postoperative period is not necessary in the diffuse toxic goiter patient if an adequate subtotal thyroidectomy has been done. In the interval between multiple-stage operations it is our practice to continue its use. This confirms the views recently expressed by Davison and Arnes.²

In elderly patients, arteriosclerotic or hypertensive cardiovascular disease may complicate the goiter problem. The standard measures to combat cardiac decompensation are indicated to overcome this additional hazard. Often, mild degrees of decompensation will respond to the treatment of the goiter problem alone. Auricular fibrillation is not a contraindication to thyroidectomy. Sometimes this annoying complication appears for the first time in the postoperative period, and quinidine has been suggested as the treatment of choice. Our experience favors waiting until late in the convalescent period before employing this drug.

More careful attention to oral hygiene in the preoperative period and refusal to operate upon a patient too soon after recovery from an acute infection of the upper part of the respiratory tract will help prevent postoperative pneumonia. When actually present, the treatment of this complication is the same as for the disease when it occurs without the added handicap of thyroidectomy. Judicious selection of serum, chemotherapy, or both will prevent a fatal outcome in a high percentage of the cases. Early recognition of atelectasis and immediate bronchoscopic aspiration of the mucous plug will prevent the development of pneumonia in the areas of the collapsed lung.

Complications strictly the result of surgery are rare in the experience of those surgeons

to sleep in bed and because he is unconscious on his trip to surgery he is spared a great deal of psychic trauma. From this point of view it is desirable. A patient's inherent toxicity, however, must not be underrated and, if the trip to the operating room causes him to react unduly, I believe it is better to recognize this before the operation than unsuspectingly proceed with the anesthetic and face the consequences postoperatively. *Avertin* masks this reaction completely. It is well to remember that *avertin*—which is tribromethanol and according to Sollman⁵, has action closely related to chloroform—produces a considerable fall in blood pressure and, since these individuals usually carry a high pressure, this fall is detrimental. With *avertin*, the pulse rate is often slower than it would be under like circumstances with another anesthetic, thus, again tending to mask the true state of affairs. It produces some liver damage and also has a deleterious effect on the kidneys.

Local block anesthetics are successfully used by many surgeons in goiter surgery. In non-toxic thyroid patients and in thyroid patients having no obstruction the use of local anesthesia is satisfactory. I do not feel that even in these cases there is any advantage over a general anesthetic. Their use prolongs the operation. In toxic thyroid patients the extra manipulating necessary to the injection of the anesthetic adds to the psychic trauma. In thyroid patients with obstructive symptoms, general anesthesia is more preferable, giving the surgeon the benefit of increased ease of handling the gland. There is also an opportunity of inserting a tracheal catheter should the occasion arise. The patient has the benefit of an environment high in oxygen and is free from the sensation of choking and difficult

breathing often associated with tracheal pressure and obstruction. After all, local anesthesia is harder on the patient than it is on the surgeon.

A combination of local and general anesthetics is often used. This may be advantageous in some cases, particularly where it may be desirable to wake the patient in the middle of the operation to test the vocal cords. Often, the skin may be incised under general anesthesia and the local injection then made, thus obviating the chance of carrying the infection through the skin with the injecting needle.

Summary

The first essential toward good anesthesia in thyroid patients is full cooperation between surgeon and anesthetist.

Nitrous oxide-oxygen or cyclopropane may both be used to advantage in thyroid surgery, the choice depending upon the patient's oxygen requirements.

Intratracheal intubation should be used in those obstruction cases definitely requiring it but should not be used routinely.

The use of *avertin* in toxic thyroids may mask important symptoms that ordinarily give warning of the possibility of delayed reactions.

THE TREATMENT OF COMPLICATIONS OF THYROID SURGERY

GEORGE E. BEILBY, M.D., F.A.C.S., Albany, New York

THE prevention of complications is the keynote of success in thyroid surgery. The brilliant results now obtained in this field of surgery have been made possible not only by an improved surgical technic but, more particularly, by the careful preoperative preparation of the patient and by the anticipa-

tion of possible complications and suitable measures directed toward their prevention.

From a mortality rate of 40 per cent in pre-antiseptic times, when hemorrhage and sepsis were chiefly responsible for this almost prohibitive death rate, we have seen a gradual drop until, now, all good goiter clinics are able to maintain a mortality rate under 1 per cent. To obtain this result requires the most careful

EXOPHTHALMOS—MODERN VIEWS ON THE CAUSE, TREATMENT, AND PROGNOSIS

JOHN C. BRADY, M D , Buffalo, New York

FOR a full century the highly complex phenomenon of exophthalmos, as seen in Grave's disease, has been the object of intensive study without any clear conception of its cause forthcoming. It can be defined as a chronic, progressive, bilateral, rarely unilateral, usually nonsymmetric protrusion of the orbital contents.

The scope of this paper limits the discussion to the exophthalmos of Grave's disease, but in passing it is well to note that the phenomenon is not limited to diseases of the thyroid gland but may be produced experimentally in low phosphorus rickets in rats (by Thompson) and is seen clinically in acromegalia, in the leukemias, in Parkinson's syndrome, in chronic nephritis, and in chronic experimental renal insufficiency. There are other clinical conditions in which it is seen, but in all, as in Grave's disease, it is a late symptom.

In about two-thirds of the cases of primary Grave's disease it occurs below the age of 45 and rarely after the decline of sexual life. If all the cases of thyrotoxicosis are included, it is present in about one-third of the number.

Etiology

Basedow thought it was due to a hypertrophy of the cellular tissues of the orbit, Sattler, W. Krauss, and others, to a venous congestion, Naffziger,² to an enlargement and weakness of the muscles. In addition, an abnormal or normal secretion of the thyroid was presupposed. All of the theories would seem to require a fixed condition in the orbits. However, we know, although Smelser's recent work,³ casts some doubt on these observations, that in the early stages of exophthalmos there is considerable variation in man and in experimental animals and that the condition may disappear after death and under general anesthesia or after section of the cervical sympathetic nerves, thus making these conjectures more or less untenable.

The discovery by H. Muller in 1858 of the smooth muscles of the orbit of mammals and his recognition of the two separate groups, i.e., periorbital and palpebral, further stimu-

lated study of these or like muscles in man and animals. Lid lag (von Graefe's sign) and widening of the palpebral fissures (Stellwag's and Dalrymple's sign) are principally due to increased tone of the palpebral muscles of Muller. It is only the protrusion of the globe in man by the increased tone of the vestigial periorbital muscle that is doubted. In lower animals it is possible, but one must presuppose a weakness in the recti muscles to produce this phenomenon in man.

A vast amount of work has been done experimentally on animals (puberal rabbits) by Grey, by Stockaert on bay ducks, and by Loeb and his coworkers on guinea pigs. Then, in 1932, Marine,⁴ Baumann, Spence, and Cjpra did extensive work on puberal rabbits.

It was found that daily injections of anterior pituitary extract could produce exophthalmos and that on a diet of alfalfa, hay, and oats, with daily intramuscular injections of 0.1 cc or more of methyl cyanide, exophthalmos was produced when an associated parenchymatous goiter existed but not until the goitrous condition was well advanced. This latter condition was always associated with hypertrophy of the anterior pituitary. Thyroidectomy always hastened the early development of exophthalmos and, when these animals were autopsied, they showed fragments of thyroid tissue still present. From this it would seem that a high-grade thyroid insufficiency but not an athyria is necessary to produce this phenomenon. Marine also found that subtotal thyroidectomy plus injections of anterior pituitary extracts promoted exophthalmos. The obvious conclusion is that it was not the thyroid hormone but rather some secretion of the anterior pituitary, either directly or indirectly, that took a positive part in the production of exophthalmos.

In addition, Marine and his coworkers found that the greatest exophthalmos was produced in the more sexually active males, with the females showing more resistance. Further experiments showed that the germinal epithelium of the testis had little, if anything, to do with the production of exophthalmos but that the interstitial cells were a prominent factor. Considerable work was done with testosterone, dehydroandrosterone and like substances, and also with estrogenic sub-

whose technic is designed to avoid known hazards. Gentle handling of the tissues by all members of the surgical team will reduce unpleasant postoperative sequelae to a minimum. One of these is edema, which may be controlled by applications of heat when the swelling is mild but which sometimes requires tracheotomy when the edema is laryngeal with respiratory obstruction.

Injury to, or removal of, the parathyroid glands results in parathyroid tetany that may appear any time from a few hours to several weeks after the operation. Fortunately, it is usually mild, is the result of temporary interference of the function of these glands, and frequently disappears before the patient leaves the hospital. Removal or destruction of too many of the parathyroid glands during the operation will result in permanent, chronic parathyroid tetany—a subject too complicated for discussion here. The immediate treatment of tetany includes the use of parathyroid extract and calcium—the former by intramuscular injection and the latter by mouth as the lactate powder or intravenously as the gluconate or chloride.

Although exposure of the recurrent laryngeal nerve has been suggested as a means of avoiding their injury during thyroidectomy, we feel that a technic designed to avoid the nerve will more certainly prevent its injury. A normal vocal cord on one side will usually compensate for a cord paralyzed by injury of its nerve on the other side, but weakness and hoarseness of the voice will persist. When both vocal cords are paralyzed by nerve injury, a permanent tracheotomy may be necessary to assure an adequate airway. Whether or not the function-restoring operation designed by King³ will prove successful in treating these problems remains to be seen. Injury to the superior laryngeal nerve results in excessive mucus production and, because it frequently supplies the interarytenoid muscles, voice changes often follow its injury.

Postoperative hemorrhage sufficient to require opening the neck has occurred only five times in the last 1,000 operations in our clinic.

Adequate and careful hemostasis at the time of operation eliminates this distressing complication that formerly was one of the greatest hazards of thyroid surgery. Similarly, postoperative infection can be eliminated by careful adherence to rigid aseptic principles. The use of drainage material increases the danger of infection, and many times a clean wound has become infected when serum collections are drained. The use of fine catgut or silk, gentle handling of tissues, and complete hemostasis will reduce the production of serum and lessen the danger of infection.

Minor complaints such as headache are easily controlled by mild sedatives or anodynes. Annoying cough and distressing mucus can be relieved by cough mixtures with codeine and by inhalations of plain steam. A high fluid intake, expectorants rather than atropine derivatives, a high humidity with constant temperature in the room help to prevent formation of mucous plugs and favor the expectoration of the tracheal secretions.

Prolonged apnea during the operation may require a tracheotomy to re-establish an adequate airway. Better premedication and careful selection of the anesthetic agent and of the technic of administering this agent will prevent most of the emergency tracheotomies during thyroidectomy. The assistance of a medical anesthetist in these matters is extremely valuable to the thyroid surgeon.

Skillful nursing care by those experienced in treating patients with goiter is important both in the preparation of the patient for operation and in the postoperative period. Constant nursing care by private duty nurses in the postoperative period is a necessity for critically ill patients.

was given. Considerable improvement has been noted

Surgically, Naffziger's operation, i.e., decompression of the orbit in the extreme advancing type, the so-called malignant type, has been a great boon and shows a high incidence of success. It should, however, be reserved for this type of case and should not be attempted for cosmetic purposes.

The prognosis, on the whole, remains rather poor.

Summation of the Symposium

Dr Donald Guthrie, Sayre, Pennsylvania—This has been a most valuable symposium on hyperthyroidism—in fact, one of the best I have ever heard—and I wish to congratulate the essayists upon their valuable contributions and the concise way in which they have presented them.

In the time allotted me to summarize the symposium, I should like to emphasize some of the most important points that appealed to me and to add briefly some facts about the disease which I consider important.

Dr Cotter did well when he warned about the conditions that might be mistaken for hyperthyroidism and stressed the importance of a careful study of the borderline cases. I agree with him that the majority of mistakes that occur are due to the anxiety and other neuroses and to neurocirculatory asthenia. I further agree with him that these patients are invariably made worse by thyroidectomy. Only careful study and experience will safeguard these patients from operation. His conservatism in treating the neurasthenia patients with mild hyperthyroidism and of withholding operation until the psychic factor has been corrected by suggestion, rest, and iodine and his conservative management of the older patient with long-standing heart disease, whether caused or complicated by toxic hyperplasia, are both excellent plans.

I have had no experience with the intravenous use of iodine for preoperative preparation and for treating postoperative reactions which Dr Jones advocates, but his results are convincing and I mean to employ it in selected cases. He was wise to warn, however, of the dangers of operating upon seriously ill patients too early, without careful study and preparation, because of

the rapid control of the toxic symptoms which the method seems to bring about.

I am glad that Dr Wetherell stressed the importance of teamwork and gentleness in the operation of thyroidectomy. I agree with him heartily in all he said about the treatment of the poles, the protection of the nerve and parathyroids, the use of fine chromic catgut or silk, and the prevention of air embolism. The movie of his operation is a demonstration of a carefully planned operative technique, keeping the important points that he stressed in his paper in mind.

To C. H. Mayo, George Crile, and Martin Tinker belong the credit of adopting and advocating polar ligations and staged operations, as suggested by Theodor Kocher, in the treatment of the severely ill thyrotoxic patient. This was the first great advancement in our knowledge of this disease, which I will discuss more fully later. We all agree with Lahey that if a goiter death occurs it was perhaps due to too much surgery or because the operation was performed at the wrong time, but it is my belief that with proper painstaking and often prolonged preoperative preparation the need for the staged operation may be greatly reduced. I shall attempt to prove this later when I review the results of our method. However, great credit belongs to these pioneers, Mayo, Crile, and Tinker, for their early efforts to control the frightful mortality of this disease before Lugol's solution was employed.

I agree with Dr Stover about the full cooperation between the surgeon and the anesthetist and that the anesthetist should be an experienced one, for he is a most valuable member of the goiter team.

Few men employ local anesthesia today. It is impossible to employ anoci-association with it, and for this reason we have never used it routinely. The protection the method offers the recurrent laryngeal nerves has been greatly overestimated, and I am convinced that it is a poor method to use with the severely ill patient. It is easy to obliterate pain sense by local anesthesia, but the sense of suffocation caused by elevating lobes that are deeply placed, adherent, or sub-sternal cannot be obliterated by local anesthesia, and many patients are terrified by this feeling of choking or suffocation. The oxygen requirements of a seriously ill thyrotoxic patient are greatly increased, therefore, ethylene or cyclopropane are much safer to use than ether or nitrous oxide. We have used ethylene for many years and are impressed with its advantages and with its wide margin of safety.

We employed avertin in about 200 cases and considered it an ideal adjunct to anoci-association. We had an unfortunate fatality due to respiratory center paralysis, and since that experience, which I reported before the Southern Surgical Association, we have discontinued its use.

I enjoyed Dr Bellby's paper very much and agree with him especially in the plan he advocates

stances in the female, who shows an increase in exophthalmos during the menstrual period when the blood estrogens are at their lowest level, suggesting that this may be the resistant factor in the female. The lack of function of the gonads in cretinism and myxedema probably explains the nonoccurrence of exophthalmos in these conditions.

Diet probably plays some part, with a disturbance between the calcium and the phosphorus ratio as found in the experimental production of exophthalmos. Aub and his co-workers have shown great losses of calcium and phosphorus, even osteoporosis, in Grave's disease.

Incidentally, the long held idea that exophthalmos could be produced by the administration of thyroxine or desiccated thyroid has been proved a myth. On the contrary, its administration is a preventative. Further experimentation along these lines was done by Donald L. Paulson² of the Mayo Foundation, and the results were presented before the American Association for the Study of Goiter in April, 1940. He used a daily injection of 1 cc or 50 guinea-pig units of an extract of anterior pituitary containing potent quantities of the thyrotropic factor—antuitrin T. Nonthyroidectomized and thyroidectomized guinea pigs were the subjects employed. Protrusion of the eyeballs occurred twenty-four hours after the first injection in 80 per cent of the nonthyroidectomized pigs and in 100 per cent of the thyroidectomized animals, reaching a maximum in ten days in nonthyroidectomized pigs and increasing in those that were thyroidectomized as long as the injections were continued and not reaching a maximum until as late as the fifty-ninth day. The protrusion of the eyeballs in the nonthyroidectomized animals reached a maximum exceeding 2.5 mm, with an average of 1.84 mm, while in the thyroidectomized animals the increase was up to 2.6 to 6.0 mm, with an average of 3.29 mm. The mean percentage of water in the retrobulbar tissues (exclusive of the lacrimal glands) of the animals given antuitrin T increased by 5.03 mm in the nonthyroidectomized animals and by 6.37 mm in those whose thyroid had been removed. The edema in the orbital tissues seemed to be responsible for the exophthalmos.

In addition to the orbital changes, there were definite changes in the skeletal muscles in both groups as early as twenty-four hours after the beginning of the injections. The muscles appeared pale on gross examination and showed diffuse Zenker's degeneration.

After three or four days, in addition to degeneration, a marked cellular reaction occurred, consisting of masses of phagocytes, giant cells, and lymphocytes. Hemorrhage due to tearing of necrotic muscle was visible at this stage. Later on, these changes were less marked, due probably to some degree of recovery. The heart muscle showed similar changes.

Sodium iodide and di-iodotyrosine given in daily doses of 100 mg failed to arrest the development of exophthalmos or muscle degeneration, but they did lessen the hypertrophy of the thyroid gland and prevent rise of the metabolic rate.

Smelser,⁵ working with guinea pigs, drew the following conclusions from a series of experiments:

- 1 The hypertrophy and pathologic modification of retrobulbar tissues found in exophthalmos, produced by the injection of anterior pituitary extract in the thyroidectomized guinea pigs, is independent of Muller's orbital muscle.

- 2 The changes are unaffected by unilateral or bilateral extirpation of the cervical sympathetic ganglia.

- 3 The ptosis created by sectioning of the cervical ganglia or by removing Muller's muscle decreases the apparent degree of exophthalmos.

- 4 Exophthalmos, produced as described and judged postmortem, is not dependent either upon Muller's muscle or upon sympathetic innervation through the cervical ganglia.

- 5 Orbital decompression as achieved in experiments does not relieve the condition of the orbital tissues but slightly decreases the degree of proptosis.

Grace and Weeks,⁶ in a review of a series of 360 consecutive cases of thyroid disease, concluded that the "postoperative regression in exophthalmos is apparent and not real."

Treatment

So far as advancing and severe exophthalmos is concerned, no satisfactory statement as to medical treatment can be made.

Helfern, in 1933, reported benefit from the estrogenic substances in humans.

The wide use of Lugol's solution has greatly lessened the incidence of exophthalmos in the past few years. Rudemann,⁴ in 1931, advised thyroid gland by mouth, and in the patients who show lower metabolic rates than the average normal, a combination of Lugol's with fairly large doses of desiccated thyroid.

performed. The basal metabolic reading wrongly interpreted is a dangerous and misleading test. Instead of using iodine in the treatment and prevention of adolescent goiter and for the preparation of the toxic case for operation, iodine is used for the treatment of hyperthyroidism, and we see many patients with quiescent adenomatous goiter seriously harmed by its use. We also see many patients who have been treated for many months with large doses of iodine, iodine refractory, or iodine fast at the time of examination and who show all the symptoms of hyperthyroidism which have returned and have continued after a quiescent period of improvement, during which time the operation should have been performed. In the minds of some it is customary to employ iodine for a week or ten days and then operate upon the patient, employing a staged operation that might have been prevented. As a matter of fact, we have found that it often requires several weeks to prepare the seriously ill patient, but we have often been rewarded by being able to perform the radical operation of thyroidectomy after this period of prolonged but careful preoperative preparation. We never decide upon first examining the patient whether a ligation, a staged operation, or a radical thyroidectomy should be performed in a particular case without careful study and careful preparation.

We are impressed with the value of fully appreciating the degree of psychic disturbance in our patients, for we believe there is no disease in which the symptoms are so much aggravated by the degree of emotional imbalance. It is for this reason that we approach these patients, studying them, preparing them, anesthetizing

them, and treating them postoperatively according to a plan that has practical psychology as its basis. It might be said that we spoil our patients with hyperthyroidism, but we are convinced that if we are to keep our staged operations at a low point and our mortality within acceptable bounds these cases must be handled by a special technic directed by those who understand the harmful effects of fear upon them.

To summarize, the methods that we employ to prevent postoperative crisis are adequate preoperative preparation, psychic support, anoxia-association, good general anesthesia, teamwork, the postoperative use of iodine, the postoperative use of oxygen, the maintenance of fluid balance, and sedation.

In our clinic we have kept our mortality within the acceptable limits. We have reduced our hospital morbidity, and we have greatly reduced the need for staged operations. For example, in reviewing the results of 1,436 patients operated upon for goiter in the last 11½ years, we find there has been but one ligation performed in our clinic in the past thirteen years. There were twenty-one staged operations performed upon 1,087 of those patients who had hyperthyroidism, with a percentage of 1.9. Among the total cases (1,436), there was a percentage of 1.4 of staged operations. There were 10 deaths among the 1,436 patients, or a mortality of 0.69 per cent. Among the 1,069 toxic cases, there were 8 deaths or a mortality of 0.74 per cent. There has been 1 death in the last 537 patients operated upon.

Permit me to express my appreciation of the honor of being invited by the section to discuss this excellent symposium upon the treatment of hyperthyroidism.

OPPORTUNITIES FOR YOUNG PHYSICIANS IN CIVIL SERVICE

is the title of an article by Dr Verne K. Harvey and Dr E. Parker Luongo that appeared in a recent issue of the *Medical Annals of the District of Columbia*. It is not generally known, as they say, that a physician in the Civil Service may participate in any phase of medical activity, ranging from a rural practice to the most highly specialized fields and that a considerable number are engaged in the general practice of medicine—for example, those employed in the Indian Service of the Department of the Interior. Young physicians may be employed under Civil Service as far south as Panama and as far north as Alaska.

They list the various fields including the Veterans Administration, with its numerous clinics, and describe the work carried on at St. Elizabeth's Hospital in Washington, D. C., which is under the jurisdiction of the Federal Security Agency. The Food and Drug Administration, the Children's Bureau in the Department of Labor, and the Public Health Service are other fields that physicians in Civil Service may enter.

Information about the openings and examinations may be obtained from the Commission's representative at any first- or second-class post office or from the Central Office in Washington.

BARE TRUTH

Girls when they went for a swim,
Once dressed like Mother Hubbard,

Now they have a different whim
And dress more like her cupboard.—Analyst

for the preparation of the seriously ill patient approaching, or in, crisis. His plan of prolonged preoperative preparation including bed rest, high calorie diet, high fluid intake, vitamins, and suitable sedatives, his use of compound solution of iodine as the specific preoperative treatment of choice, and the psychotherapy he employs are all excellent ideas.

I am glad to note that by the proper preparation and selection he has reduced the need of staged operations to less than 5 per cent in his work. He is correct when he says that a technic planned to avoid the nerve rather than expose it will surely prevent less injury to the nerve and, as he has wisely pointed out, the use of silk, gentle handling of tissues, and adequate hemostasis will reduce the production of serum and lessen the need for drainage and the danger of postoperative infection.

I also enjoyed Dr. Brady's paper on exophthalmos. My experience with progressive exophthalmos is naturally, and I am glad to say, limited. It is interesting to note in reports that the majority of patients who develop this distressing and rare complication are men and that most of them are in a state of mild hypothyroidism. Two of our 3 patients improved under conservative measures, directed to keeping the metabolic rate slightly above the normal time. Both of these patients had unusually good results. The third patient received an excellent result from a double Krönlein operation (a much less radical one than the Naffziger operation), but the Naffziger operation, in spite of its magnitude, provides relief to the patient with the progressive type whose sight is imperiled.

To appreciate what changes have taken place in the treatment of hyperthyroidism perhaps a short account of my early experiences with this disease will be of interest. In 1906 I became associated with C. H. Mayo as a member of his goiter team, and I recall with interest the tragic experiences we had with the patients who were seriously ill with hyperthyroidism, for postoperative crises were extremely common and the mortality was extremely high. Von Eiselsberg lost 3 of his first 4 cases, C. H. Mayo lost 4 of his first 18 patients, 3 of the next 30, 1 in the next 75, and 4 in the next 278.

Irrespective of the degree of intoxication, all patients received the same radical form of surgical therapy. They were brought to the operating room and anesthetized on the operating table with ether, and a unilateral lobectomy was performed upon each of them. This was before the use of saline and glucose infusions and before oxygen was employed therapeutically. The postoperative thyroid storms were terrible to observe and to treat. In those days the house staff believed that any patient who was strong enough to survive the operation for thirty-six hours would probably recover. C. H. Mayo and Plummer noticed that an operation performed too soon after a crisis almost always

proved to be fatal, and they decided from this experience to withhold operation for a few months after a crisis. This was the first conservative step suggested in the treatment of hyperthyroidism.

In 1908 Kocher advocated the use of preliminary polar ligation, a method adopted by all surgeons in this country who were brave enough to treat the disease surgically. And, as a result of preliminary ligations, the multiple-stage operations developed. This method of treatment was suggested and advised by Mayo, Crile, and Tinker. The patient seriously ill with hyperthyroidism was subjected to two or more polar ligations, performed two or three months apart. Then a partial lobectomy was done, followed in three months by a second partial lobectomy, often employing the use of boiling water (suggested by Miles Porter) to destroy some of the parenchyma of the gland after the ligations or during the period between the lobectomies. As a result of this plan—and it was then the only safe plan to treat those seriously ill with the disease—several months, a year, and sometimes even a longer time elapsed before the surgery could be completed and the patient restored to health. The psychic, the physical, and the financial strain placed upon these patients was almost unbearable, but as a result of the method the mortality fell constantly. In those days the use of iodine was taboo, because Kocher noticed that its use produced toxic symptoms in quiescent nodular goiter—the type so common in Switzerland—and he warned against the use of iodine in the treatment of goiter. Following the master without using their heads, all surgeons in America gave up the use of iodized catgut and the use of iodine to prepare the skin of the operating field, and the regrettable thing about it was that these patients were crying for iodine in large amounts.

In 1922 Plummer advocated the use of iodine in the preparation of the patient with hyperthyroidism. His plan of treatment, based upon his theory of its beneficial effect upon the disease, is so well known that I shall merely refer to it as the greatest contribution to our knowledge and treatment of the disease. It has done more to reduce the mortality and the morbidity of hyperthyroidism than any suggestions made before or since that time. The isolation of thyroxin by Kendall in 1914, together with its effect upon the basal metabolic rate, has also increased our knowledge, and practically all surgeons use iodine in preparation and the basal metabolic rate to estimate the degrees of hyper- and hypothyroidism.

Unfortunately, in spite of all that has been written, there is a misunderstanding in the minds of many about these important subjects. Too much reliance is placed upon one metabolic reading, often taken incorrectly, without a careful and painstaking study of the patient, with the result that an uncalled-for operation is often

The specificity arises not from the state or the site but from the type of the invading organism. A diphtheritic infection of the genitalia is a specific infection as truly as though it involved the fauces and the larynx. The location modifies the symptoms, the course, and the result. The same is true of other types of organisms which invade the female genital tract, though, of course, there may be several types of organisms involved in the process of which one may be dominant. Pasteur pointed out the fact that streptococci produced genital infection in the puerperal period, and for many years the streptococcus represented more or less of an entity as distinguished from the staphylococcus and the diplococcus.

The epidemic character, the contagious nature, and the carrier idea having been developed and promulgated, there remained certain cases that could not be explained fully by such an hypothesis. The theory developed that there might be two categories of puerperal fever which could be defined as exogenous and endogenous infections. One author remarks that the latter theory was more often based upon an excuse rather than upon scientific data. This is either facetious or unjust, since there are undoubtedly cases in which the infectious agent is present in the patient at the time of delivery. This idea of endogenous infection must be based upon one of two conceptions. First, that a pathogenic organism is present but inert prior to confinement or that a nonpathogenic bacterium becomes pathogenic subsequent to the change in environment from a pregnancy to the puerperium.

It is difficult to define an endogenous infection because of the impossibility of knowing exactly when the offending organism was introduced into the genital tract. Personally, the terms exogenous and endogenous infection do not appeal to us, since they confuse rather than clarify the picture. The genital tract tends to be noninfectious and has a natural flora determined by tissue and chemical conditions.

In classifying infections from a clinico-pathologic point of view, it is important to attempt to clarify the factors involved. This might be done by recognizing that infections of the genital tract may be antepartum, intrapartum, or postpartum and that during these periods they may be latent or active. All genital tract infections may be regarded as either contact or metastatic. All contact infections occur either from the woman

herself or from some attendant who brings the organisms to her through various mediums. Metastatic infections are relatively uncommon, but organisms lying in remote portions of her body and gaining access to the blood or lymph channels may become deposited in the genital tract and excite inflammation. The types of organism involved in any of these processes may vary greatly from time to time depending upon their prevalence and from case to case depending upon environment and susceptibility of the individual. Various organisms have been and still are associated with puerperal infection, but at this time we are concerned with the most prevalent and serious variety of infectious agent which occurs in inflammation of the puerperal genitalia. The streptococcus discovered by Mayerhofer was isolated by Pasteur from cases of puerperal fever, and for a long time all streptococci were considered to belong to one and the same group.

We know now that while all streptococci have certain identical morphologic characteristics and many cultural propensities in common their pathogenetic properties differ markedly. As with puerperal fever so with other diseases, they were at first clinical entities that could not be classified until their etiology was established. In some instances, the clinical picture was so clear that when the etiologic agent was found the disease entity persisted. This is well illustrated by scarlatina and erysipelas. Puerperal fever does not belong to such a group, consequently, one has to define such a clinical picture according to the infecting agent. This becomes progressively of greater importance when the treatment becomes more specific. The relationship between various diseases also becomes clearer as we learn that the etiologic agent is the same even though the manifestations vary with the condition of the patient and the site of attack. It has long been noted that certain cases of puerperal fever had an erythematous rash, but it was not clear that scarlet fever and certain types of puerperal fever were the same until it became known that certain strains of streptococci produced an erythrogenic toxin. It is difficult to trace the exact course of our knowledge of the streptococcus family. At first all cocci seem to have been included in the same morphologic group. Certain characteristics were noted, such as a tendency to multiply in chains, in groups, or in packets. Subsequently, certain differences were noted in their growth products, and the strepto-

STREPTOCOCCIC PUERPERAL INFECTION

FRED L. ADAIR, M D , and LUCILE R. HAC, PH D , Chicago

THE history of our knowledge of puerperal infection parallels the development of our knowledge from the realm of the unknown—surrounded by superstition, the supernatural, and mystery—to that of the known with proved facts and intelligent interpretation.

There is no reason to doubt that females of many species have succumbed to genital infection and that puerperal infection has caused death since animal life began. There is no doubt of its existence among the primitive tribes, of more recent times, who have had no means of recording the events that affected them. The earliest medical chronicles point definitely to the existence of such afflictions that the incantations of the medicine men and priests were powerless to control. Thousands of years passed with no conception entering the human mind as to the nature of this disease. Within the past two centuries various advance guards among the physicians have suggested that it might be a transmissible disease. The physicians from Hippocrates to Paré inclined to the idea that this disease was associated with lochial retention or suppression. The epidemic character of the disease seems to have been recognized early during the seventeenth century in Leipzig, in Paris, in Copenhagen, and in Normandy. The first suggestion as to its possible relationship to other types of infection seems to have been made by Pouteau (1750), who described an epidemic in the Hotel Dieu de Lyon under the title "Inflammation erysipelateuse du bas ventre."

Less than one hundred years ago a few advocates of the contagious theory were decried and denounced for suggesting that unclean hands could possibly "be the minister of evil" to the mother in labor. Although Young, Cedersjöld, Gordon, and others antedated Holmes and Semmelweis, their observations were not emphasized by becoming controversial and their ideas lay dormant awaiting the advent of the historic mind interested in delving into the records of the past. Leuwenhoeck with his lenses,

Koch with his anthrax, and Pasteur with his streptococci illuminated the path that was blazed by their forerunners. The work of Tarnier, DePaul, Siredey, and others supplemented the efforts of their predecessors, and the epidemic and contagious character of the disease came to be accepted. It was shown that outbreaks were more common in hospitals and cities than in homes and the country. Tarnier (1858) proved that in the same sections of Paris the maternal mortality was 1 to 19 in the hospitals and 1 to 322 in the homes. Tenon demonstrated that conditions within the hospitals influenced the mortality in l'Hotel Dieu by comparing that of 1786 with that of 1836. He attributed a reduction in the mortality to the fact that in 1786 more than 1 patient occupied the same bed while in 1836 each patient had a separate bed.

Siredey (1861), by separating the sick women from the well, was able to reduce the mortality from 68 to 25 per cent. It is hardly possible for us to believe that about eighty years ago 1 woman out of 40 who delivered in a hospital died. One of the earliest and most striking examples of carrier infection was the case of Dr. David Rutter (1843) who had a maternal mortality of about 20 per cent while his contemporaries had a nominal one. He gave up his obstetric practice for a time but subsequently resumed it with a corresponding result. If he had cured his ozena, more of his patients would doubtless have survived.

Lister, by his application of the scientific knowledge of Pasteur, established surgical antiseptics, which combatted wound infection. The recognition of bacteria in general led to the discovery of different types related to definite disease entities. The recognition by Koch of tuberculosis and the establishment of his postulates proving the specificity of the tubercle bacilli were the landmarks by which the relation of a type of bacteria to a given disease could be proved. Puerperal infection was not a specific disease, and the name should be interpreted to mean a time and place relationship. In other words, it indicates only that during the period of the puerperium the woman is suffering from an infection that originates in, and spreads from, the genitalia.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Department of Obstetrics and Gynecology, the University of Chicago and the Chicago Lying-in Hospital.

and blood stream extension, either singly or in combination. The former is essentially a lymphangitis and the latter is a thrombophlebitis with or without emboli. Blood stream infections may be direct into the uterine sinuses or indirect through the lymphatic channels. The latter mechanism prevailed in the epidemic described by Watson. The direct lymphatic spread is the prevailing one, and in severe cases the infection spreads through the uterine wall like water through a sponge and a general peritonitis results. Surface extension rarely occurs in streptococcic puerperal infection. This is more characteristic of gonococcic infections.

Remote organ involvement occurs either from lymphatic spread or from blood-born emboli. Massive infarction may cause sudden death. Various strains have different behavior. The hemolytic types tend to produce anemia and vary greatly in their invasive properties. Butler and Hill are of the opinion that encapsulated forms resist phagocytosis and have high invasive characteristics. They believe Lancefield A is the most frequently potent type. Infection with B is generally mild but occasionally severe. Infections with C and G are usually mild.

Clinical types consist of antepartum, intrapartum, and postpartum infections. Metastatic infections may develop during pregnancy, but antepartum infections are more commonly associated with ruptured membranes and delayed onset of labor. Intrapartum infections usually arise in protracted labors often with ruptured membranes, frequent vaginal manipulations and poor aseptic technic. So-called postpartum infections may be truly postpartum, usually from poor technic in puerperal care. They are generally the result of contact infection in the terminal second-stage, third stage, or immediate postpartum period. Carriers, poor aseptic technic, contact from infected urine or feces, in addition to the contributory factors, are responsible for these infections.

Most authors find that the hemolytic streptococci are responsible for their cases, but some point to the frequency of the anaerobic type of infection. The clinical course depends upon the virulence of the organism, the acrimony of infection, and the resistance of the patient. Fever, chills, varying clinical findings together with leukocytosis, positive uterine smears, and cultures, and positive blood cultures determine the diagnosis. The degree of fever varies from slight to high, is usually

irregular, and attains irregular high peaks associated with chills in the thrombophlebitic type.

The treatment consists of the prophylactic, which is accomplished by overcoming anemia, maintaining proper nutrition, and eliminating the foci of infection. Specific immunization has been tried but its value has not been proved. We have immunized over 1,100 patients with no deaths, but the postpartum febrile morbidity of these patients was not better than our general morbidity. All of these patients were skin sensitive to streptococcic toxins. Some gave a history of antecedent streptococcic infections and others gave no such evidence. There was no significant difference in the morbidity of these two groups. Our evidence, as well as that of others, indicates that the value of antepartum immunization is at least doubtful.

The most important preventive treatment is the avoidance of carriers and infectious contacts and of poor aseptic technic, trauma, and blood loss prior to, during, and subsequent to labor. Up-to-date aseptic and antiseptic technic must be employed. Patients must be kept in a constantly clean environment and infected persons, whether patients, attendants, or visitors, must be kept away from the parturient woman. Antiseptic vaginal instillations have been advocated and used by some. All these details are too extensive for discussion at this time.

The treatment of the actual infection consists of proper rest, nutrition, and nursing care. Transfusions overcome anemia and have supportive and nutritive value. Specific therapy is now available with the sulfonamides, of which three are of proved value—sulfanilamide, sulfapyridine, and sulfathiazole. The relative value of these has not been finally determined. The latter two are certainly less toxic. The first named is of great value in treating hemolytic streptococcic infections but is of no help in curing those due to anaerobic streptococcus. The second is of specific value in pneumococcic infections. The last is more specific for staphylococcic and gonococcic infections but may prove useful in hemolytic streptococcic infections as well. Inasmuch as sulfonamide therapy is of such proved value in hemolytic streptococcic infection, which is the most frequent type in serious and fatal cases of puerperal fever, the following procedures are recommended. There is no time for discussion of pros and cons of the sulfonamides, so this rather specific information is given.

cocci were placed along with certain bacilli in the category of those bacteria that ferment sugar and usually produce lactic acid. This property and their ability to grow aerobically and anaerobically, to form chains, and to stain positively with Gram's method are the common characteristics of all streptococci, and for some time no further differentiation was made. The picture was somewhat confused because the environment sometimes altered the growth tendencies of certain organisms. Morphologic characters seemed to be the starting point for the classification of the streptococcus group. At first there was the subdivision into the long and the short chain streptococci. Such characteristics are variable and not pathognomonic, though, in general, the former are pathogenic to man and the latter are either weakly or not at all pathogenic. All varieties are parasitic and exist in the mouth and upper parts of the respiratory and gastrointestinal tracts. The latter relatively harmless group also occurs in dairy products. The fact that certain types had hemolytic properties and others had not led to the next step in the recognition of the various types. Much confusion arose which more recently has been overcome by the use of differential cultural methods. Schottmueller (1903), who pioneered in using blood cultures for diagnosing infectious diseases, was able to show the hemolytic power of certain strains of streptococci on blood agar plates.

This basic method led to the subdivision of streptococci into the green-producing *Streptococcus viridans* and the hemolyzing *Streptococcus hemolyticus* strains. A third strain that produces no change in blood cells has also been recognized. Schottmueller recovered anaerobic streptococci from the blood of patients with puerperal infection, many of whom had thrombophlebitis. Colebrook, Schwarz and Dieckmann, and Brown have called attention to this observation and confirmed it with some of their own. This variety is for the most part saprophytic, but under certain circumstances it is pathogenic to man. As a group it is nonhemolytic and is gas-producing.

These observers believe that these streptococci are frequently present in the flora of the normal vagina. Fermentation, agglutination, precipitin and antigenic reactions have been used to type the hemolytic streptococci successfully. On the basis of such cultural and biochemical characteristics Lancefield and others consider it possible to differentiate

into serologic groups streptococci from human, bovine, and other sources. Colebrook and his associates have proved that certain strains of hemolytic streptococci are pathogenic to man and others to animals and that still other strains are nonpathogenic. He believes that pathogenic hemolytic strains are rarely found in the vagina. Lancefield has classified these strains into A, B, C, D, etc., by the use of the precipitin tests with extracted polysaccharides. Griffith has been able to subdivide further the group from human sources—that is, Group A into many types of which at least thirty-two have been differentiated.

While much knowledge has been gained there is much to be learned. It is clear that the hemolytic attribute is no longer an index of pathogenicity and that the streptococcus in common with organisms causing fermentation can grow, though not luxuriantly, under either aerobic or anaerobic conditions. We now know that certain strains can produce an exotoxin that has erythrogenic properties—as in scarlet fever and certain forms of puerperal infection. This strain does not, however, seem always to elaborate this exotoxin, as shown by the observations of Plass and his coworkers and others. Various studies indicate that pathogenic hemolytic streptococci seldom occur in the genital tract of pregnant women but, on the other hand, the non-hemolytic nonpathogenic and the anaerobic streptococci do occur. Of the Lancefield strains, Group A is pathogenic to man and causes scarlet fever, puerperal sepsis, erysipelas, septic sore throat, or pneumonia. These strains are not specific for any one disease but may cause scarlet fever in one patient and puerperal sepsis or erysipelas in another. Groups B and D are associated with mild infections and may be found in the antepartum genital tract and also in the human throat. D occurs in the human intestinal tract also.

It seems clear that there is an anaerobic strain of streptococcus which is pathogenic to man, attacks dead tissue, produces infection, especially postabortal, invades thrombi, and causes thrombophlebitis. Colebrook has recognized one group as pathogenic and another that is not.

The primary pathology of streptococci puerperal fever is that of a wound infection of the vulva, the vagina, the cervix or the placental site. The contributory factors are infectious contacts, trauma, and blood loss. Mild streptococcal infections may remain localized but the tendency is for lymphatic

and blood stream extension, either singly or in combination. The former is essentially a lymphangitis and the latter is a thrombophlebitis with or without emboli. Blood stream infections may be direct into the uterine sinuses or indirect through the lymphatic channels. The latter mechanism prevailed in the epidemic described by Watson. The direct lymphatic spread is the prevailing one, and in severe cases the infection spreads through the uterine wall like water through a sponge and a general peritonitis results. Surface extension rarely occurs in streptococcic puerperal infection. This is more characteristic of gonococcic infections.

Remote organ involvement occurs either from lymphatic spread or from blood-born emboli. Massive infarction may cause sudden death. Various strains have different behavior. The hemolytic types tend to produce anemia and vary greatly in their invasive properties. Butler and Hill are of the opinion that encapsulated forms resist phagocytosis and have high invasive characteristics. They believe Lancefield A is the most frequently potent type. Infection with B is generally mild but occasionally severe. Infections with C and G are usually mild.

Clinical types consist of antepartum, intrapartum, and postpartum infections. Metastatic infections may develop during pregnancy, but antepartum infections are more commonly associated with ruptured membranes and delayed onset of labor. Intrapartum infections usually arise in protracted labors often with ruptured membranes, frequent vaginal manipulations and poor aseptic technic. So-called postpartum infections may be truly postpartum, usually from poor technic in puerperal care. They are generally the result of contact infection in the terminal second-stage, third stage, or immediate postpartum period. Carriers, poor aseptic technic, contact from infected urine or feces, in addition to the contributory factors, are responsible for these infections.

Most authors find that the hemolytic streptococci are responsible for their cases, but some point to the frequency of the anaerobic type of infection. The clinical course depends upon the virulence of the organism, the atrium of infection, and the resistance of the patient. Fever, chills, varying clinical findings together with leukocytosis, positive uterine smears, and cultures, and positive blood cultures determine the diagnosis. The degree of fever varies from slight to high, is usually

irregular, and attains irregular high peaks associated with chills in the thrombophlebitic type.

The treatment consists of the prophylactic, which is accomplished by overcoming anemia, maintaining proper nutrition, and eliminating the foci of infection. Specific immunization has been tried but its value has not been proved. We have immunized over 1,100 patients with no deaths, but the postpartum febrile morbidity of these patients was not better than our general morbidity. All of these patients were skin sensitive to streptococcic toxins. Some gave a history of antecedent streptococcic infections and others gave no such evidence. There was no significant difference in the morbidity of these two groups. Our evidence, as well as that of others, indicates that the value of antepartum immunization is at least doubtful.

The most important preventive treatment is the avoidance of carriers and infectious contacts and of poor aseptic technic, trauma, and blood loss prior to, during, and subsequent to labor. Up-to-date aseptic and antiseptic technic must be employed. Patients must be kept in a constantly clean environment and infected persons, whether patients, attendants, or visitors, must be kept away from the parturient woman. Antiseptic vaginal instillations have been advocated and used by some. All these details are too extensive for discussion at this time.

The treatment of the actual infection consists of proper rest, nutrition, and nursing care. Transfusions overcome anemia and have supportive and nutritive value. Specific therapy is now available with the sulfonamides, of which three are of proved value—sulfanilamide, sulfapyridine, and sulfathiazole. The relative value of these has not been finally determined. The latter two are certainly less toxic. The first named is of great value in treating hemolytic streptococcic infections but is of no help in curing those due to anaerobic streptococcus. The second is of specific value in pneumococcic infections. The last is more specific for staphylococcic and gonococcic infections but may prove useful in hemolytic streptococcic infections as well. Inasmuch as sulfonamide therapy is of such proved value in hemolytic streptococcic infection, which is the most frequent type in serious and fatal cases of puerperal fever, the following procedures are recommended. There is no time for discussion of pros and cons of the sulfonamides, so this rather specific information is given.

Sulfonamide Therapy

Severe Infections

Sulfanilamide—maintain blood level at 10–15 mg/100 cc

- Dosage
- a 0.5 Gm trial dose
 - b Large initial dose (3–5 Gm)
 - c 5–8 Gm daily divided in equal 4-hour doses

Sulfathiazole

Dosage 3–6 Gm daily divided in equal 4-hour doses

Blood

Daily hemoglobin, cell volume, white blood count, and blood level unless otherwise specified

Mild Infections

Sulfanilamide—maintain blood level around 5 mg/100 cc

- Dosage
- a Trial dose 0.5 Gm
 - b 4–5 Gm daily for 3 days in 5 equal doses
 - c 3 Gm daily for 4–10 days in 5 equal doses

Sulfathiazole

- Dosage
- a. 3 Gm for 2 days in 6 equal doses
 - b 2 Gm for 6–8 days in 4 equal doses

Blood

Daily hemoglobin, cell volume, white blood count, and blood level unless otherwise specified. Collect approximately same time of day, 1st, 2nd, 3d, 5th, 7th, 9th days

If peritonitis occurs, the Wangensteen gastrointestinal drainage is helpful. Localized drainage of abscesses is naturally essential, but heroic treatment of diffuse peritonitis by surgical procedures is of doubtful value. The attempt to ligate thrombosed pelvic veins will result in many casualties and can hardly be justified. The treatment of streptococcal puerperal fever has become specific for the Lancefield groups. There is also some specific chemotherapy for other types of infection which do not come under consideration at this time. This is no reason for in any way relaxing preventive measures that, on the whole, are more effective than any curative therapy.

Discussion

Dr Milton G. Potter, *Buffalo, New York*—It is presumptuous on my part to attempt to discuss the opinions that were presented so clearly by such an authority as Dr Adair. I believe it can be said without exaggeration that his individual efforts have done more to reduce maternal mortality in this country during the past three years than anyone else's. While he is internationally known as a textbook author

and teacher, his fame will stand out in American obstetric history for his pioneer work with the American Committee on Maternal Welfare and his development of the American Congress of Obstetrics and Gynecology.

I am naturally in accord with what was said and am only speaking to re-emphasize in my own words some of his remarks that I feel are not generally well understood by the medical profession.

Puerperal fever is now the greatest cause of maternal mortality and, while great advances in the past twenty years have reduced the incidence, it is my distinct impression that in this locality during the past five years the incidence of maternal mortality from sepsis remains fairly constant in spite of the advent of the sulfonamides, which could be called glory dust, for it appears to be used for everything indiscriminately.

Considerable confusion still exists concerning the classification of streptococci and the use of sulfonamides.

It must be kept in mind that in general there are two types of streptococcal puerperal infections which are clearly defined and differentiated clinically and bacteriologically.

By far the most common type is that caused by the anaerobic streptococcus, which exists in the vagina prior to delivery, is ordinarily innocuous to the individual, and only becomes pathogenic or runs wild when the individual resistance of the patient is lowered by long labors, ruptured membranes, trauma, hemorrhage, or shock.

The 8 cases of sepsis which died in Erie County last year probably belonged in this type. Six of these were delayed cesareans and 2 were spontaneous deliveries.

No amount of chemotherapy will change the course of this infection, which varies in severity and is usually characterized by irregular fever, foul-smelling lochia, thrombophlebitis, and a pulse that is slower than one would expect with the existing temperature.

I have been taught that the greater the smell the better the prognosis in these cases.

Quite different is the puerperal infection caused by the Group A hemolytic streptococcus. This organism is definitely pathogenic to the human, is introduced by indirect or direct contact and, fortunately for all concerned, is a rarity.

The rarity of this organism in the parturient case is no doubt due in part to the meticulous care taken in most hospitals concerning the proper masking of nursing and medical attendants to avoid the contact of a possible carrier and is probably also due to the improved obstetric technic and the more frequent use of consultations.

This virulent type of infection is usually characterized clinically by a high, or moderately high, temperature with a rapid pulse, the lochia

is clear or sanguinous and for the most part odorless. If the cultures from the vagina, cervix, or uterus show this type of organism, sulfanilamide is indicated. It must be remembered that sulfanilamide is only of specific value in this type of infection. The clinical classification of antepartum, intrapartum, and postpartum infections, as suggested by Dr Adair, clarifies our thoughts on this subject. His discourse on the preventative and prophylactic treatment is clear and cannot be overemphasized. It has been my experience with this infection during the postpartum period that transfusions of smaller amounts of blood more frequently seem more beneficial than massive transfusions.

We have, but, of course, rarely—since one must be pretty certain in his diagnosis—resorted to the use of the Porro operation when confronted

with antepartum and intrapartum localized uterine infections with satisfactory results, and the advent of the supravaginal section also offers possibilities in these types of infections.

In summarizing I would reiterate that sulfanilamide is of therapeutic value only in the aerobic Group A hemolytic streptococcal infections and that its action is not bactericidal but bacteriostatic.

While I do not believe that chemotherapy should be used in minor febrile disturbances, I would, if confronted with a definite postpartum puerperal infection, immediately institute sulfanilamide therapy and then obtain cultures from the vagina, uterus, and cervix. I would continue the therapy only if a hemolytic streptococci, *Bacillus coli*, or *Bacillus welchii* were reported, and I would add to that therapy supportive measures mentioned by the speaker.

PHYSICIANS FOR SERVICE IN THE ARMY OF THE UNITED STATES

While at present no appointments are being made in the Medical Corps Reserve, additional physicians are needed for service in the Army in connection with the current military program. Appointments, however, are being made in the Medical Corps, Army of the United States, in which a very large number of vacancies exist, to bring the Medical Department to required strength and to furnish replacements for medical officers now on duty.

Peacetime regulations governing the Medical Corps Reserve apply to appointments in the Medical Corps, Army of the United States. Candidates must be between the ages of 24 and 36, hold the degree of Doctor of Medicine from an approved medical school, be licensed to practice medicine in a State, Territory, or in the District of Columbia, and be engaged in the ethical practice of medicine. License to practice and actual practice of medicine may be waived for recent graduates engaged in graduate training. All applicants must meet physical standards.

While appointments may be granted on successful completion of the prescribed four-year course of medical instruction, such appointees are not eligible for active duty until they shall

have completed at least one year's hospital internship. They are then available for active military duty. If there are sufficient medical officers to meet the military requirements, it may be possible to grant deferment of active duty for the purpose of pursuing further graduate training.

Appointments, other than for the purpose of assignment to affiliated medical units of individuals associated with the sponsoring institution and upon recommendation of institution authorities, will not be made at this time of applicants above the age of 35. All such appointments will be in the grade of lieutenant.

In the event of a national emergency, these restrictions will be removed, thus permitting the appointment of qualified individuals above the present age limit and in grades commensurate with their professional training and attainments.

It is strongly urged that young physicians, especially those who are completing internships, residencies, or other graduate training, make application for appointment as First Lieutenant, Medical Corps, United States Army. Inquiries should be addressed to The Surgeon, Second Corps Area, Governors Island, New York.

TO REHABILITATE PATIENTS WHO HAVE BECOME VOICELESS

through loss of the larynx, a clinic has been opened at the National Hospital for Speech Disorders, according to Dr James S. Greene, medical director. Treatment is given to develop a substitute voice, and at the same time social aid is given the patient to help him readjust to his surroundings.

The hospital also is undertaking a series of

brain wave studies to determine if stuttering can be correlated with specific brain wave patterns and whether anxiety induces any significant changes in the patterns. Dr Donald J. Simons, working under the supervision of Dr Harold G. Wolff of the Cornell University Medical College, is in charge of the study program, which is made possible by special grants.

OVARIAN CANCER

Clinicopathologic Evaluation

ANDREW A. MARCHETTI, M D, New York City

IF, AS Millar¹ has put it, "the history of cancer has been the history of one of the great failures of man," the record of cancer of the ovary has been the history of one of the great failures of the gynecologist. When an analysis is made of the reported end results of the treatment of ovarian cancer, the same distressing and dismal note is universally sounded—the outcome is poor. The present evaluation will be no different insofar as the end results are concerned, since one will find them as discouraging as any reported. However, gloomy as the outlook may appear from our past experiences with cancer of the ovary, rays of hope and encouragement break through that vast amount of untiring world-wide cancer research in anticipation of the day, be it far or near, when its baffling and nebulous barriers will be fully penetrated by the discovery of its cause or prevention and, eventually, of its adequate treatment and universal cure. Careful study and review, from time to time, of the clinical data and observations that accumulate in well-conducted clinics is vital, for as Sir James Paget once said "We are bound to search everywhere and in all ways."

No apologies need be advanced for the number of patients reviewed in this report, for while they may be considered numerically small they are sufficiently numerous to lend themselves satisfactorily to analysis. The completeness of the data and follow-up especially enhance the value of the study. The analysis, from the clinicopathologic approach, is made as a preliminary study with two special objectives in view—namely, to obtain a better perspective of what has been our experience with cancer of the ovary in the stated period of time that has elapsed and to secure in whatever way possible a better approach to the problem for the future.

Statistical Data

The statistics in this report are based upon 7,009 individual admissions to the Gynecological

Service in the Woman's Clinic of the New York Hospital and covers the period of eight years and four months from September 1, 1932, to January 1, 1941.

During that time there were 1,164 ovarian cysts (neoplastic and nonneoplastic) and tumors found among the 7,009 individual patients, representing only the lesions that were actually diagnosed subsequent to macroscopic and microscopic study of all the pathologic material. The clinic incidence of these particular ovarian cysts and tumors then is found to be 16.6 per cent or 166 per thousand. Of the 1,164 instances, 1,104 or about 95 per cent were considered benign, while 60 or about 5 per cent were diagnosed as cancer. Thus, for this clinic, the ratio of benign to cancerous ovarian growths is approximately 19 to 1. However, if the 776 nonneoplastic lesions are deducted, the remainder constitutes a total of 328 primary benign neoplasms of the ovary establishing a ratio of these new growths to cancer of the ovary of about 5½ to 1 (see Table 1).

A diagnosis of cancer of the female genital tract was made in 351 patients, a clinic incidence of about 5 per cent or 50 per thousand. Tables 2 and 3 indicate its distribution according to lesions and organs and reveals that 60 cases or 17.1 per cent involved the ovaries, consequently making the clinic incidence of cancer of the ovary 0.85 per cent or just more than 8 per thousand (Table 4). The 60 patients with ovarian cancer were cases in which the diagnosis was unequivocal and excluded 13 cases in which the diagnosis was qualified by such phrases as, "potentially malignant," "malignant tendencies," "essentially benign"—phrases sufficiently disturbing to the pathologist and clinician to warrant treatment in many instances as though the lesion were cancer. Later, it will be pointed out that a closer histologic study of the tumor tissue and the clinical course of the patients in this special group justify, for the time being, their removal from the cancer group.

Table 1 indicates the manner in which the cases of ovarian cancer were classified, and shows the predominance of serous cystadenocarcinoma, 44 cases or 73.3 per cent. It also shows that the serous type, in our experience,

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Department of Obstetrics and Gynecology the New York Hospital and Cornell University Medical College.

TABLE 1.—CANCERS OF THE OVARY

	Cases	Per-centage
Serous cystadenocarcinoma	41	73.3

Total number of primary benign neoplasms	328	84.5
Total number of cancers of the ovary	60	15.5
	388	100.0
Ratio of primary benign neoplasms to cancer—about 5 1/2:1		

is over seven times more prevalent than the pseudomucinous type, 6 cases or 10.0 per cent. There were 5 cases of teratoid or embryonal adenocarcinoma—some of these undoubtedly would be designated as mesonephroma ovarii by Schiller—4 cases of granulosa-cell carcinoma, and 1 case in which squamous-cell carcinoma was found in a well-encapsulated dermoid cyst.

Clinical Data

Since the greater part of the ovarian cancers in this clinic consisted of serous cystadenocarcinoma, a fact that conforms to practically all reported clinicopathologic statistics, the analysis here will be confined to the 44 cases falling under that category.

One soon learns that the symptomatology appears late and that the early stages of the disease are insidious and go unrecognized. It is primarily for these reasons that, unfortunately, the doctor, as a rule, is not sought until the disease is considerably well advanced. The two most common complaints that appeared in over 70 per cent of the patients in our series are noticeable, oftentimes rapid enlargement or "swelling" of the abdomen and lower abdominal pain. Depending upon the extent and nature of the involvement, such complaints as dyspnea, nausea and vomiting, constipation, backache, anorexia, a general feeling of fatigue or weakness, loss of weight, and to a lesser degree vaginal bleeding may accompany or may appear independently of the two aforementioned commonest complaints.

No age is exempt of the disease. The earliest case occurred at 23, the oldest, at 74 years of age. However, from Table 5 one notes that 75 per cent of the cases occurred between the ages of 40 and 60. Serous cystadenocarcinoma of the ovary essentially is a

*There were 8 cases in whom x-ray therapy was considered inadequate.

upon the physician that the most scrupulous pelvic examination must always be recorded, irrespective of how relevant or irrelevant is the rest of the examination and history, particularly her menstrual history. The earliest detection and investigation of pelvic masses, especially ovarian masses of any size, with prompt and complete excision where indicated, are the factors that will bear most fruit if we are to improve the outcome of the patients ultimately succumbing to cancer of the ovary.

All but 3 of the 44 cases of serous cystadenocarcinoma underwent some form of laparotomy. On 29 occasions generalized carcinomatosis was noted with gross evidence of metastasis to the omentum, rectum, colon, tubes, uterus, liver, or lungs in various cases. It is obvious that such hopeless findings in so many of our patients must have accounted for the poor results that will be considered later. Fixed and adherent unilateral or bilateral ovarian masses with or without a ruptured capsule but without gross evidence of carcinomatosis or metastasis were observed in 9 cases. A well-encapsulated tumor was found free in the abdomen in 6 patients, 5 of whom had unilateral tumors, 1, bilateral. Abdominal ascites was present in 21 cases and in 6 additional ones was accompanied by hydrothorax. The tumor was found to be unilateral in 8 cases (18.2 per cent) and bilateral in 36 (81.8 per cent).

Treatment

The manner in which our patients with serous cystadenocarcinoma were treated varied. As indicated in Table 6, a course of x-ray therapy was combined with extirpative surgery or exploratory laparotomy, or both, in 38 cases. They, as well as their results, are separated into three main groups. The first group includes 23 patients in whom roentgen-ray therapy was preceded by complete or partial surgical removal of the tumor and pelvic organs. Eighteen patients in this group died with an average duration of life lasting sixteen months. Survival in all in-

stances is computed from the time treatment was initiated. Five patients are alive 1, seven years and five months, and the remaining 4 average, to the present time, eleven months' survival. The second group consists of 7 patients who had an exploratory laparotomy followed by x-ray irradiation. A generous biopsy of the primary tumor or of a metastatic nodule was obtained in each case at the time of laparotomy. Practically all of the cases in this group were inoperable. Five are dead, with an average survival of nine months, whereas 2 are still living 1, thirty months, the other, five months. The third group comprises 8 patients whose x-ray therapy was preceded by an exploratory laparotomy and then followed by an operation in which some part or all of the pelvic organs and the tumor were removed. Unquestionably, the x-ray rendered operable a good part of previously inoperable cases in this group. Seven of them have died, with an average duration of life lasting seventeen months, and 1 is still living twelve months. X-ray irradiation was given to 3 hopelessly inoperable cases subsequent to paracentesis, 2 of which died before adequate irradiation could be completed and the other dying two months after adequate dosage was administered. Finally, there were 3 patients who did not survive the initial surgical procedure. They succumbed to postoperative complications—2 died of pneumonia within two weeks and 1 died of pulmonary embolism a month after the operation. They may be regarded as constituting an operative mortality of 6.8 per cent.

X-ray therapy to patients with cancer is outlined for each individual patient, and it is the happy and close cooperation of our Radiology Department that makes it possible to plan for the patient's best advantage. The size and number of portals and the total dosage that is administered depend upon the size and condition of the patient and the extent of the involvement of the disease in the pelvis and the abdomen. In general, x-ray therapy is administered to patients with ovarian

cancer as follows four to six portals of entry varying in size from 150 to 225 sq cm are employed, 200 r (in air without backscatter) are given daily to each of two portals, and the portals are rotated in order until each one has received a total of from 1,800 to 2,400 r. The accompanying physical factors used are 200 kilovolts, 1.0 mm copper plus 1.0 mm aluminum filtration and 50 to 70 cm skin target distance. A total dose of 1,800 r, or over, per portal is considered adequate. In our series, 8 patients received inadequate treatment.

The current belief that surgery combined with x-ray irradiation is the most satisfactory and beneficial method at our disposal to treat cancer of the ovary or that every patient operated upon for ovarian cancer should be given postoperative irradiation, although generally true, is much too inclusive and needs to be qualified. The fact that early and complete excision of any type of tumor by surgical operation continues to be the most desirable path to follow in the field of treatment does not require elaboration. Nor can it be denied that roentgen-ray therapy with its associated improvement of technic and equipment is an indispensable palliative measure and does prolong life. However, when one does contemplate the use of x-ray irradiation with surgery, it would appear to be of the greatest importance to take cognizance of the type or kind of tumor of the ovary that is being treated, as well as the stage of its progression and involvement. Much is yet to be learned of the effect of x-rays on the various types of ovarian cancer. If we consider the cases of serous cystadenocarcinoma in our series, the results as shown in Table 6 fail to reveal striking advantages in the three main groups already referred to. True, the number of cases is too small to draw any final conclusions and, in addition, it should be recalled that the greater number of our patients did not appear for relief and treatment before the disease was well advanced. Nevertheless, there is substantial positive evidence in the data pertaining to the patients who have died of serous cystadenocarcinoma to support the following inference. While one considers the fact that in the far-advanced cases, 50 per cent of the time, the element of pain was introduced as frequently as it was relieved, that over 40 per cent of the patients more than mildly complained of some of the adverse effects of radiation (diarrhea, dysuria, nausea, anemia), that abdominal distention from ascites made its reappearance in some cases

sooner than anticipated, and that the duration of life was only slightly, and so often only painfully, prolonged, one wonders whether the use of the roentgen ray in such cases really can be considered palliative. From our experience one has to infer that it is not.

On the other hand, where there is complete excision of a tumor that is grossly well encapsulated and free or only adherent to adjacent structures without evidence of metastasis, or where the primary ovarian cancer is completely extirpated with total or partial removal of local metastasis, postoperative irradiation is of the greatest value and comfortably prolongs the patient's life for a considerable period of time. There were 6 patients in our series who had presumably well-encapsulated serous cystadenocarcinomas lying free in the abdomen. 5 with unilateral tumors and the other with bilateral ones. They were operated upon, the tumors and the pelvic organs were removed, and they all had adequate postoperative radiation. Five of these patients succumbed as a result of recurrences, the average duration of life being three years and three months. The sixth patient is still living after two and one-half years without evidence, so far, of any recurrence.

That postoperative irradiation proved beneficial in the management of these patients, even though there is no five-year survival among them, one has no refutable argument to advance, since our series lacks the group of patients that would run parallel for comparison—that is, patients operated upon under the same conditions but not subsequently treated by x-rays. There are statistical reports representing the collected and individual experiences of other clinics which show that adequate postoperative x-ray irradiation greatly improves the outcome of patients treated for ovarian cancer when compared to those simply receiving surgical treatment.

Mortality

Table 7 demonstrates the outcome of 60 cases with ovarian cancer according to year and the kind of tumor. Not enough time has elapsed for final deductions, but it is apparent from the small number of patients among the living that little can be hoped for by way of improvement. As it is, the mortality rate for the entire series is 78.3 per cent and, if the year 1940 is excluded because of its recency, it rises to 83.3 per cent. For serous cystadenocarcinoma the mortality

51-60	0	0.0
61-70	3	23.1
	13	100.0

is 81.8 per cent and, again excluding the year 1940, it rises to 87 per cent

Consideration of a Special Group

At this point I should like to consider the 13 patients with histologically benign papillary serous cystadenoma. This group displays a more encouraging picture. The predominant complaints, just as in the definite cancer group, were enlargement of the abdomen (7 cases) and pain in the lower part of the abdomen (5 cases). A striking difference in the history of these patients as contrasted to those with carcinoma was that the enlargement and distention of the abdomen occurred more rapidly or within a shorter period of time—respectively, two to four months as compared to one to two years. Laparotomies were performed on all patients, and in every case complete removal of the primary tumor was possible. The tumor was unilateral in 3 cases (23.1 per cent) and bilateral in 10 cases (76.9 per cent). Bilateral ovarian tumors with the uterus were removed in 8 patients, without the uterus, in 2 of them. Extirpation of a unilateral tumor alone was effected twice on the left side and once on the right. A ruptured capsule, with papillary growths breaking through the surface, was found in 9 cases, adhesions to adjacent structures, in 8, ascites, in 4, and peritoneal implants, in 2. In 4 patients, a well-encapsulated tumor was found free in the abdomen. Adequate postoperative x-ray irradiation

was administered to 9 patients. Four cases had no x-ray therapy, 3 because of their comparatively old age (65, 66, and 67 years) and 1 because she was thought to be too young (aged 29 years). One finds a 30 per cent five-year survival in this group. Of the greatest importance is the fact that these patients are as closely followed as the cancer patients and that up to date they are all alive and in good condition, with negative pelvic findings as well as without evidence of recurrence. An interesting observation is found in Table 8 demonstrating the age incidence. Here, the majority of cases, 61.5 per cent, has shifted to the two earlier decades when contrasted to the period between 40 and 60 years of age in the cancer group.

It was stated previously that inasmuch as these were considered histologically benign cases of papillary serous cystadenoma it was not deemed justifiable to include them in the malignant group, even though about 70 per cent had clinical evidences that could be interpreted grossly as characteristic of carcinoma. The timidity of the pathologist and clinician to assume the responsibility that the lesion was entirely benign clinically as well as histologically often prompted the recommendation for postoperative x-ray irradiation as though it were malignant.

This group of patients will indeed prove to be the most interesting to follow, for only time will disclose the accuracy of the histologic interpretation and of the good prognosis that has been associated with the patient.

Histopathology

A separate discussion of the histopathology of the various types of ovarian cancer considered is not permissible within the scope of this paper. However, special attention is directed to a consideration of the papillary serous cystadenoma because of its predomi-

nance in the cancer group and because of the implications it carries in the special group where it has been interpreted as histologically benign.

That the histologic distinction between a benign and cancerous ovarian cystadenoma, especially the papillary type, is not infrequently difficult is universally admitted. In general, extremely few errors in diagnosis are made in the interpretation of the well-recognized morphologic patterns that characterize the unequivocal histologically benign and malignant papillary serous cystadenoma. Nevertheless, it seems obvious that more effort should be invested in an intensive study of the histologic variations of this type of tumor, particularly the more complex variations of the apparently benign type that is so frequently designated as "potentially malignant" or "of low-grade malignancy." Moreover, a correlation of the microscopic evaluation should always be made with the pathologic anatomy found at the time of operation and with the clinical course of the patient. Whether a papillary serous cystadenoma of the ovary is small or large, unilateral or bilateral, whether the capsule is intact or has been penetrated, whether or not there is dissemination of the growth by metastatic implants to the surface of the pelvic organs and of the peritoneal cavity, whether there is ascites or not—these are all important factors that must be considered and properly weighed, but they do not ultimately determine whether the neoplasm is benign or not.

In the final analysis, for the greater majority of cases, it is the correct interpretation of the histologic picture which will correspond to the outcome of the disease. What one sees under the microscope, and the exact interpretation of it, is still the most valuable criterion upon which prognosis and subsequent treatment should be based. Indeed, the best trained pathologist and clinician is misled occasionally and learns that what was thought to be a benign process eventually turned out to be malignant. But the error in this direction is negligible when one considers how often a benign process is diagnosed carcinoma or sarcoma and how such a misinterpretation so often vitiates the "better" results reported in the treatment of cancer of the ovary. Likewise, the same misinterpretation credits the beneficial palliative effect of x-ray therapy with more than it deserves.

The morphologic pattern of the benign papillary serous cystadenoma in its simplest

form is reduced to broad and short connective tissue stalks lined by a single layer of cuboidal or low columnar epithelial cells many of which are ciliated. The nuclei are uniformly ovoid and mitosis is never seen. Invaginations into the connective tissue form simple cystic spaces and glands lined by the same epithelium.

With growth and proliferation the papillary processes elaborate into longer and finer connective tissue stalks continuing to support, for the most part, a regular and single layer of serous epithelium. Parallel to the papillary development, the glandular elements become more numerous so that the structure appears more cystic with a reduction and displacement of the connective tissue. Yet, any actual invasion or break in the continuity of the basement membrane supporting the epithelium is not to be seen.

The branching becomes more complex and develops into a luxuriant papillary growth in which the broader, as well as the thinner, supporting stalks may be lined by a double or triple layer of epithelium instead of a regular single layer. Absence of mitotic figures is still noted and, whereas the cells in the stratified areas may appear a little compressed and spindle-shaped with a more elongated nucleus, cellular and nuclear polymorphism is not so definite that one can promptly classify it as malignant. It is fair to assume, as Brakemann² points out, that the capacity of the tumor to grow more rapidly at this stage accounts for its breaking through the capsule and for its tendency to form implantation metastases.

Beyond this point a few mitotic figures make their appearance, and definite changes in the form of the cells and the nuclei are established so that the transition may be reached and a papillary serous cystadenocarcinoma may develop. Where one is to draw the line between a benign process and early malignancy is still difficult, but it is felt that if more effort is expended in attempting to make as correct an interpretation of the histologic findings as possible it will enable one to understand to a better advantage the clinical course and outcome of the disease.

No attempt has been made to classify the serous cystadenocarcinomas into papillary, semicystic, solid, medullary, or scirrhous, since it is presumed that they have a common origin and represent various forms and stages in development of the same process.

Conclusion and Summary

The evaluation of our experience with cancer of the ovary is revealing in several interesting ways. Undertaken as a preliminary study it has proved of some value in provoking points for further discussion and serious thought. Most striking is the fact that the outcome of our patients has been extremely poor and that a way must be sought to improve our end results.

The determination of the incidence of ovarian cancer, its ratio to benign primary neoplasms of the ovary, and other related comparisons and percentages as calculated for this clinic are only of comparative value but do serve the purpose of substituting fact for impression for those who are statistically inquisitive. Sixty cases of ovarian cancer were reviewed and since 73.3 per cent or nearly three-fourths were diagnosed as serous cystadenocarcinoma, most of the analysis was confined to the 44 cases included under that category.

A summary of the clinical data reveals that the symptomatology, age incidence, and physical and pathologic findings generally conform to the observations that have been repeatedly made. Until some clue or sign that will disclose the early development of ovarian cancer can be made available, it is urged that women between 40 and 60 years of age submit themselves periodically to routine pelvic examination. One is aware that this plea is repeatedly made, but it always bears emphasis and the present study indicates, just as others in the past have, that the investigation of pelvic pathology in its earliest stages is the most important factor that will contribute to the improvement of the outcome of cancer, especially ovarian cancer.

The results in treatment, though disappointing, are not surprising when it is learned that most of the patients presented themselves in the more advanced stages of the disease. Surgical operation with early diagnosis and complete extirpation, or with the removal of the primary tumor and as much of the local metastasis as possible, combined with adequate postoperative x-ray irradiation, is the most hopeful procedure at our disposal in the management of patients with cancer of the ovary. Although the palliative effect of x-ray irradiation is appreciated and its use generally recognized as indispensable, from our experience in the inoperable cases and certain far-advanced cases of serous cystadenocar-

cinoma it is concluded that x-ray therapy has little, if any, beneficial remedial effect. Not only the stage of involvement of the disease should be considered when the administration of roentgen-ray therapy is contemplated but also the type or kind of ovarian tumor. Our knowledge of the consequences of x-ray upon the various types and kind of ovarian tumors is incomplete.

The mortality rate is high—78.3 per cent for all the cases and 81.8 per cent for serous cystadenocarcinoma. If the year 1940 is excluded because of its recency, the rates rise to 83.3 and 87 per cent, respectively. Indeed, the computation of these percentages covers a short and most recent period of time but, with only a single patient among them a five-year survival, there is little to expect by way of improving the outcome of the patients in this series when it will be reconsidered five years hence.

The group of patients that will be followed with the greatest interest is the one of 13 patients who are considered to have histologically benign papillary serous cystadenoma. They are a special group inasmuch as the diagnosis was qualified and most of them were treated as though the lesion were cancer. Still it did not appear justifiable to include them in the definite cancer group, inasmuch as it is believed that such cases just now would vitiate the results. Only the passing of time with periodic review of the tumors' histology and vigilant follow-up of the patients' clinical course will bring forth a sound evaluation of the true nature of their activity.

A discussion of the histopathology places emphasis on the thought that a correct interpretation of the histologic findings is the best criterion upon which to base the clinical course and outcome of the patient. No difficulty is encountered by the pathologist in diagnosing the unequivocally benign and malignant tissues. However, particularly in the papillary serous cystadenoma, a better understanding of the transition stages is encouraged, since a greater number of the more complex variations of the relatively benign type is often diagnosed malignant. Misinterpretation in the opposite direction is less frequent.

In closing, it is appropriate to say that as we confront the problem of cancer one finds eternal optimism reigning over an undercurrent of pessimism. "The facts are here, a medical Newton must come and arrange them for us," and to quote Leitch: "A future generation, knowing surely the cause of can-

cer, will have no patience with our floundering, or guesses, and our continued arguments" Let us hope that that Newton or that generation is soon forthcoming

Discussion

Dr Ward L Ekas, Rochester, New York—It has been a great pleasure to hear the interesting paper presented by Dr Marchetti A study of the 69 cases of ovarian cancer occurring in our clinic revealed essentially the same results as you have just heard

The symptoms of this dreaded disease appear late and are insidious in their appearance There are no symptoms in the early stages of this disease, and it is not unusual to see a patient late in the disease who has had symptoms for no longer than two to four weeks Indeed, 40 per cent of our cases gave a history of symptoms for a period less than four months Gastrointestinal symptoms occur as early as any, they are in many forms, such as nausea and vomiting, flatulence, distention, sense of fullness, and particularly constipation, which is seen in a rather large percentage The constipation is usually described as an increasing constipation Pain occurred in over half of the cases and varied from an uncomfortable heavy sensation to sharp and knifelike Vaginal bleeding is not too commonly seen but does occur in a certain percentage of the cases Since many of the patients are past the menopause, it is significant, when it does occur, in warning the patient that all is not well At times, the patient discovers a tumor mass in the lower part of the abdomen Grouping the symptoms, one can say that many of them are those of malignancy in its last stages Ascites occurs frequently

In our group of cases, 29 were carcinoma, 31, malignant papillary cystadenoma, 5, adenocarcinoma, 3, embryonal or of the mixed cell type, and 1, a malignant pseudomucinous cyst Thirty-eight of the cases had operative removal of the tumor, and in 20 more cases an exploratory laparotomy or paracentesis was done

In the treatment it would seem that preoperative x-ray is rarely indicated, for it seems better to make a diagnosis before resorting to x-ray therapy unless it is a hopeless case Operative removal, of course, is to be done in all cases in which it is possible Paracentesis may be neces-

sary in not a few cases before laparotomy, and in some of the cases malignant cells may be found in the fluid

Subsequent x-ray therapy should be given, although the results have been anything but encouraging It was used in only twenty-four of our cases Since the depth dose is the important factor, we use a 70-cm. skin target distance and a 220-kilovolt peak A filter of 0.5 mm of copper and 1.0 mm of aluminum is used Six portals are used, giving two per day of 150 to 225 sq cm The dose per portal is 1,600 r in air The patients are measured anterior-posteriorly and laterally so as to try to arrive at a depth dose in the parametrial region, estimated at perhaps 2,000 to 3,000 r

There have been 4 five-year cures in our series Two cases had tumors of the solid mixed cell type, 1, carcinoma in a ruptured cyst, a fourth, a malignant papillary cystadenoma A fifth patient, who had carcinoma, is alive and apparently well after four and one-half years Most of the patients were dead within a year after being first seen

One of the objectives noted was to secure, if possible, a better approach to the problem of the future This to my mind may be done in two ways First, women must be educated to the need of a periodic health examination With the cancer teaching they are already becoming more and more cancer conscious and are coming to the doctor for more routine examinations Already in our clinic a limited well-woman clinic has been started for the purpose of semi-annual breast and pelvic examinations.

The second way is to emphasize to the medical student during his school years the need of a routine pelvic examination This means repeated and frequent pelvic examinations under supervision and description of the findings It is our practice in teaching to do just this thing so that our graduates may feel a fair degree of confidence in interpreting a pelvic examination

Furthermore, every doctor should be taught to consider a pelvic examination as important a part of a physical examination as the heart or lungs Such an examination should include the use of a vaginal speculum to view the cervix Particularly those patients over 30 years of age should be examined Every sizable ovarian tumor should be removed and the small ones watched, if they do not disappear in a short time, they, too, should be removed While some small benign cysts may be removed, the more important potentially malignant or malignant ones will be removed

A THOUGHT

It would be tragic if people had to wait as long for the doctor to come as he waits for his money

Discussion

Dr Ward L Ekas, Rochester, New York—It has been a great pleasure to hear the interesting paper presented by Dr Marchetti. A study of the 69 cases of ovarian cancer occurring in our clinic revealed essentially the same results as you have just heard

The symptoms of this dreaded disease appear late and are insidious in their appearance. There are no symptoms in the early stages of this disease, and it is not unusual to see a patient late in the disease who has had symptoms for no longer than two to four weeks. Indeed, 40 per cent of our cases gave a history of symptoms for a period less than four months. Gastrointestinal symptoms occur as early as any, they are in many forms, such as nausea and vomiting, flatulence, distention, sense of fullness, and particularly constipation, which is seen in a rather large percentage. The constipation is usually described as an increasing constipation. Pain occurred in over half of the cases and varied from an uncomfortable heavy sensation to sharp and knife-like. Vaginal bleeding is not too commonly seen but does occur in a certain percentage of the cases. Since many of the patients are past the menopause, it is significant, when it does occur, in warning the patient that all is not well. At times, the patient discovers a tumor mass in the lower part of the abdomen. Grouping the symptoms, one can say that many of them are those of malignancy in its last stages. Ascites occurs frequently.

In our group of cases, 29 were carcinoma, 31, malignant papillary cystadenoma, 5, adenocarcinoma, 3, embryonal or of the mixed cell type, and 1, a malignant pseudomucinous cyst. Thirty-eight of the cases had operative removal of the tumor, and in 20 more cases an exploratory laparotomy or paracentesis was done.

In the treatment it would seem that preoperative x-ray is rarely indicated, for it seems better to make a diagnosis before resorting to x-ray therapy unless it is a hopeless case. Operative removal, of course, is to be done in all cases in which it is possible. Paracentesis may be neces-

sary in not a few cases before laparotomy, and in some of the cases malignant cells may be found in the fluid.

Subsequent x-ray therapy should be given, although the results have been anything but encouraging. It was used in only twenty-four of our cases. Since the depth dose is the important factor, we use a 70-cm skin target distance and a 220-kilovolt peak. A filter of 0.5 mm of copper and 1.0 mm of aluminum is used. Six portals are used, giving two per day of 150 to 225 sq cm. The dose per portal is 1,600 r in air. The patients are measured anterior-posteriorly and laterally so as to try to arrive at a depth dose in the parametrial region, estimated at perhaps 2,000 to 3,000 r.

There have been 4 five-year cures in our series. Two cases had tumors of the solid mixed cell type, 1, carcinoma in a ruptured cyst, a fourth, a malignant papillary cystadenoma. A fifth patient, who had carcinoma, is alive and apparently well after four and one-half years. Most of the patients were dead within a year after being first seen.

One of the objectives noted was to secure, if possible, a better approach to the problem of the future. This to my mind may be done in two ways. First, women must be educated to the need of a periodic health examination. With the cancer teaching they are already becoming more and more cancer conscious and are coming to the doctor for more routine examinations. Already in our clinic a limited well-woman clinic has been started for the purpose of semi-annual breast and pelvic examinations.

The second way is to emphasize to the medical student during his school years the need of a routine pelvic examination. This means repeated and frequent pelvic examinations under supervision and description of the findings. It is our practice in teaching to do just this thing so that our graduates may feel a fair degree of confidence in interpreting a pelvic examination.

Furthermore, every doctor should be taught to consider a pelvic examination as important a part of a physical examination as the heart or lungs. Such an examination should include the use of a vaginal speculum to view the cervix. Particularly those patients over 30 years of age should be examined. Every sizable ovarian tumor should be removed and the small ones watched, if they do not disappear in a short time, they, too, should be removed. While some small benign cysts may be removed, the more important potentially malignant or malignant ones will be removed.

A THOUGHT

It would be tragic if people had to wait as long for the doctor to come as he waits for his money.

FOLLOW-UP STUDY OF ARTHRITIC PATIENTS TREATED WITH ACTIVATED VAPORIZED STEROL

R. GARFIELD SNYDER, M D , F A C P , and WILLARD H. SQUIRES, M D , F A C P ,
New York City

THE progress of a one-year follow-up of the original 23 cases of arthritis treated with Ertron and described in the *New York State Journal of Medicine*¹ will be reported briefly at this time. Although an extensive study on a group of 100 patients is now being conducted in our clinic, it is considered important at this time to record the roentgenologic and laboratory results, as well as the clinical progress observed during the past twelve months, in the original series of cases.

A detailed discussion of these cases appeared in the previous report,¹ and the reader is referred to the original table on page 710 of the May, 1940, issue of the *JOURNAL*. Data obtained during the past year is tabulated in the same manner and listed under the same case numbers as in the original report so as to show a complete record of each patient covering a period of from two to four years (Chart 1).

In the follow-up study of these patients the following factors received special attention: (1) toxicity, (2) blood changes, (3) weight, (4) radiographic studies, (5) results obtained in 23 cases of arthritis treated with activated vaporized sterol for a three-year period, and (6) permanence of improvement. A summary of each of these findings is presented in the following conclusions.

Clinical Findings

(1) *Lack of Toxicity*—The minor and infrequent toxic reactions to Ertron exhibited by the patients in this study were in sharp contrast to the more serious and frequent toxic reactions reported by Bauers and his associates² when they used large doses of vitamin D produced by ultraviolet irradiation of ergosterol under the Wisconsin patent.

The occasional signs of intolerance that have followed the use of Ertron have all been temporary. These disturbances included nausea, vomiting, moderate diarrhea, and frequency of urination. To protect the patients against these gastric symptoms they were instructed to take Ertron with a glass of milk. When a slight nausea developed it

usually yielded to either rhubarb and soda or sodium bicarbonate. The most severe complications resulting from the use of Ertron disappeared within a week or ten days after withdrawal of the drug.

The appearance of gastric distress was not found to be consistent with any increase of the blood calcium as has been claimed by others. In fact, some of the cases in which there was a temporary elevation of blood calcium showed no signs of intolerance, while those who did have digestive upsets had normal blood calcium values.

(2) *Blood Calcium Changes*—There is no consistent change in the blood calcium—some cases showing a fall, some a rise, and others no change. It is interesting to note that Case No. 4, who has taken 8 capsules daily for four years, still has a blood calcium of 10.6 mg. We consider from 10.0 to 11.5 mg. per hundred cubic centimeters as being normal. In this connection, one of us (R. G. S.) recently encountered a blood calcium of 16 in a perfectly normal woman suffering from a mild attack of osteoarthritis of the knee whose previous medication had been salicylates.

Blood sedimentation rate—The sedimentation rate has not been of much value in indicating the progress of these cases. In some with the greatest clinical improvement the sedimentation rate remained unchanged or has even increased. In other cases with the sedimentation rate approaching the normal, the patient's degree of improvement has been slight. Other data on blood chemistry and blood counts reveal no consistent changes that can be correlated with the progress of the disease.

(3) *Weight*—Most of the cases showed an increase in weight. This is probably due to some quality in the Ertron which in massive doses makes optimum nutrition possible, especially in the undernourished rheumatoid type of arthritis. There are several research projects in large universities attempting to explain this question at the present time. Just how Ertron acts we do not know, but one point is obvious from the clinical findings: It does seem to act as a powerful "tonic." One of the early signs of Ertron administra-

From the Arthritis Clinic, Hospital for the Relief of the Ruptured and Crippled.

Case No	Follow-Up X-Rays*	Follow-Up Blood Chemistry	Cal- Phosphorus	Follow-Up Sedimentation Rate	Present Joint Condition	Present Physical States	Remarks	Results
1	No further change. More flexion, contraction	10	2 27	2	Still further diminution of swelling and pain Increased functional activity	Able to do all her housework	No medication in seven months, then recurrent pains which disappeared with resumption of medication	Good
2	Patient moved to Washington				Dropped from clinical roll			Eliminated from this study
3	Suggestion of early ankylosis of wrists	9	6 3 25	50	Disappearance of pain and soft tissue swelling	Able to do housework including washing	Had three relapses which were traceable to emotional stress due to illness in family All symptoms disappeared each time with continuation of Ertron therapy	Slight improvement
4	Original films show marked destructive changes in hands and wrists. Follow-up films identical	10	6 2 56	25	Disappearance of pain and stiffness	Full time employment Drives delivery truck	On Ertron three years with maximum dose of 8 capsules daily No elevation of blood calcium	Excellent
5	Further destruction of distal interphalangeal joints	10	3 03	10	Unchanged	Difficult to evaluate as patient refused to cooperate	Uncooperative. Medication stopped Patient refused to attend Clinic regularly	Eliminated from this study
6	No further changes in films	9	4 2 61	36	Unchanged	Difficult to evaluate as patient refused to cooperate	Absent from Clinic four to five months at a time	Eliminated from this study
7	No further changes in films	9	5 3 09	10	No pain or swelling	Normal function of all joints	No medication in one year Patient free from rheumatic pains	Excellent
8	No further changes in films	10	3 2 94	18	Normal	Does all own housework	No medication in eight months. Free from all rheumatic symptoms	Excellent
9	Decreased bone density Diminution of soft tissue swelling	11	3 09	17	Occasional stiffness. No pain	No pain. Finishing high school	No medication in one year Normal appearance and functional activity	Excellent
10	No further changes in films	9	2 45	12	Less stiffness	No limitation of activity	Still under medication and continues to improve	Good
11	No further changes in films	13	8 2 56	6	Marked diminution of pain, stiffness and swelling	Normal functional activity	No medication in past six months	Good
12	No bone changes Less soft tissue swelling	8	6 3 85	94	Less pain and swelling	Improved functional activity Able to play golf last summer	Blood calcium lower despite large doses of Ertron	Slight improvement
13	Calcareous deposits in soft tissues in fingers	12	3 4 69	138	Unchanged	Less anemic. Performs all household duties	Sedimentation rate remains high	Slight improvement
14	Patient working and unable to attend Clinic for follow up x-rays and blood studies Sent letter answering our questions				Less swelling	Able to work	States appetite is good. General improvement without medication in eight months	Good
15	No further changes in films	10	6 3 85	27	Less swelling	Very active Free from pain Plays all children's games	Patient weighs only 48 pounds due probably to faulty diet and to great amount of activity Has taken 6 capsules of Ertron daily yet blood calcium shows a fall	Excellent
16	Less soft tissue swelling Same content of bones higher	10	5 2 75	18	Absence of pain, stiffness and swelling Appears normal	No limitation of motion. Performs all household duties	Normal appearance and normal activity in spite of no medication in two months	Good
17	Osteoporosis and rarefaction seen May 5 1939 not present on December 11 1940	10	5 2 36	9	Absence of pain stiffness and swelling Appears normal	No limitation of motion. Performs all household duties	Normal appearance and normal activity in spite of no medication in four months	Excellent

18	Patient unable to attend Clinic for follow-up x-rays and blood studies Sent letter answering our questions			No pain or swelling Occasional cramps in fingers	Improvement in systemic condition. Increased functional activity	Varicose ulcer prevents the patient from working at the present time	Slight improvement
19	Patient working and unable to attend Clinic for follow-up x-rays and blood studies Sent letter answering our questions			Less pain and swelling Joints swell when weather changes	Able to work	Improved functional activity Carrying on normal regular routine in spite of no medication	Good
20	No further changes in films	10 0	3 43	38 Unchanged	Some pain in shoulders and right ankle	Patient shows slight improvement only Able to work but has some pain	Slight improvement
21	No further changes in films	10 5	2 10	14 No change	No change	Very emotional and has preconceived ideas about what various forms of therapy will do Discontinued Ertron	Failure
22	No further changes in films	9 2	2 36	18 Less swelling Much more motion	Able to dance	Has gained 30 pounds while on this therapy	Excellent
23	No previous x-rays for comparison	13 8	4 38	145 Unchanged	Becoming weaker No improvement probably due to some other systemic condition. Age of patient is 62	This case developed a severe anemia and study is being conducted to ascertain its cause. An undiscovered malignancy is suspected	Failure

* Due to lack of foresight on our part we did not take the precaution of using absolutely the same technic in all our cases in the first series, but the results must be fairly accurate since all the plates were taken by the same technicians and interpreted by the same radiologist. The notes on the follow-up of the x rays are a short abbreviation by us of the reports of the radiologist.

tion is a markedly improved sense of well-being and a definite improvement in nutrition.

(4) *Radiographic Studies of the Bones and Joints*—In our experience the x-ray studies of the bones and joints are of no definite value in determining the clinical progress of the disease. Even over a period of four years significant changes are rare. The bone consistency and joint spaces remain practically unchanged. Under this form of treatment a diminution of soft tissue swelling is often seen in the follow-up films. In order to compare accurately the follow-up films with those obtained previously, the films should be taken with the same technic and interpreted by the same radiologist.

Many clinicians in the past have attempted to use recalcification of the arthritic bones as a measure of improvement following Ertron therapy, but in our experience there is no justification for this claim.

(5) *Clinical Results Obtained in 23 Cases of Arthritis Treated with Activated Vaporized Sterol over a Three-Year Period*—We appreciate that no definite conclusions can be drawn as to the relative therapeutic value of any medication on the results obtained in only 23 cases. The results we are reporting may not be considered by some to be brilliant

when they are compared with the more glowing reports of results obtained by many other forms of treatment for arthritis. Most of these latter reports, however, include the results obtained in early cases—that is, cases of less than one-year duration. It is our contention that the inclusion of these early cases in any scientific report makes the report of questionable value, because many of these early arthritic cases can be alleviated by almost any form of treatment. We feel, however, that our results are in reality better than the figures would indicate, because all of our cases had suffered from their arthritis for from two to five years before receiving Ertron treatment and each had proved to be resistant to most of the accepted forms of therapy prior to the administration of Ertron.

It is a well-known fact among the medical profession that it is most difficult to be intellectually honest when trying to evaluate the clinical results obtained in any group of cases treated by oneself. In order to eliminate this factor as much as possible we selected cases that had been unsuccessfully treated by other forms of medication. As a further safeguard the patients were all treated by one of us (W. H. S.), but the end results were observed and recorded by the senior author.

(R. G. S.), who had nothing to do with the treatment. The clinical progress of many of the cases was also observed by members of the staff, and in no instance was there any serious disagreement with our clinical judgment in reporting the results obtained.

Psychic effects. The influence of emotional stresses on the arthritic process has been receiving a vast amount of attention during the past few years. Because of this, it was necessary to rule out any beneficial influence that might be brought about by the psychic factors incident to the patients coming to a group of specialists for a new form of treatment. At the present time this is being studied in great detail in one of our large universities. A preliminary study of this factor by Dr. Reed³ of the University of Illinois indicates that the beneficial effect following Ertron therapy is due to the Ertron and not to the psychic factors, because, when a placebo was substituted for the Ertron without the patient's knowledge, the patient invariably complained of increased pain and stiffness. If the placebo was used before Ertron therapy was started, then the patient showed no improvement until Ertron was administered. Furthermore, since the patients in our series have all been subjected to numerous types of therapy without any beneficial results, we feel that it is not likely that they would be enthused about another form of therapy unless they were definitely benefited by it.

We also appreciate that no one is warranted in arriving at a definite conclusion as to the efficacy of any new form of treatment until he has personally observed the cases treated for no less than a five-year period. In most of our cases the observation period has been at least three years.

(6) *Permanence of Improvement*—One of the most important questions to be answered is the permanence of the relief or cure—

whether or not relapses follow the cessation of the drug. Most of the patients during this follow-up period were able to return to their normal gainful activity either without any medication or on a small maintenance dose of Ertron.

The progress of each case is listed in Chart 1. Some cases who received no medication for varying lengths of time since Ertron therapy was stopped remained free of pain and other rheumatic symptoms. Other cases, especially those who had not received Ertron in adequate dosage for a sufficiently long time, state that the pains recurred when the medication was stopped but disappeared again when the Ertron administration was resumed. In some cases that suffered from recurrences, definite extraneous causes were discovered to explain these relapses. This phase of the subject will be taken up in detail in a future report.

Conclusions

1. We believe that Ertron is an agent that has definite value in the treatment of arthritis.

2. We feel that its use is not associated with any more danger than is usually encountered with other accepted forms of therapy if the medication is given under the advice and control of a physician.

3. It is too early to praise its relative value, but it is now being tried in other well-organized clinics. At the end of a five-year period we will be in a better position to appraise its clinical value more exactly.

THE LONE SINNER

An evangelist, conducting a revival service in a small town, in the midst of one of his sensational sermons commanded all in the house who were paying their honest debts to stand up. Every man, woman, and child—with one exception—rose to their feet. The preacher then ordered them to be seated. "Now, let everyone not paying his honest debts stand up."

The lone exception, a careworn, albeit professional-looking individual in spite of his dingy,

frayed, last year's suit, slowly assumed a perpendicular position.

"How is it, brother, that you are the only one in this congregation who is not meeting his just obligations?" inquired the preacher.

"I am a physician," he answered meekly, "and most of the brethren are on my books, and—"

"Let us all join in hymn number 299," said the preacher hurriedly.—*Jackson County (Mo.) Medical Society Bulletin*

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the January 1 issue and will concern "Hypnotics and Sedatives."

Management of the Menopause

DR. CHARLES H. WHEELER. The subject of this conference is the "Management of the Menopause." We thought this was a subject peculiarly appropriate for a conference for several reasons. In the first place, menopausal symptoms are among the commonest that the practitioner has to deal with, second, one does not find an adequate discussion of the subject in the standard textbooks of medicine and therapeutics, and, third, we are fortunate in having as a member of the staff of this hospital Dr. Ephraim Shorr, who is one of the pioneers in this field.

DR. EPHRAIM SHORR. If you will permit me I should like first to review briefly the pathophysiology of the menopause in order to indicate the bases for its therapeutic management. With regard to terminology, the menopause is, strictly speaking, the actual cessation of ovarian activity, whereas the climacteric is the period of transition resulting in this cessation. This may occur spontaneously or may be induced or accelerated by measures that depress ovarian function, such as radiation or by the removal of the uterus or ovaries or both.

The problems associated with this condition range beyond the age period of the actual transition and, indeed, may be present for many years thereafter. While the most important events at this time are the quiescence of ovarian activity and the reduction in the amount of estrogenic hormone available to the organism, many other significant changes occur at this critical period. It is likely that the pituitary and thyroid glands undergo some alteration in function. This is the period of the highest incidence of myxedema, and increased amounts of pituitary gonadotropic hormone appear in the urine. Other biologic changes also take place. The climacteric ushers in the decrescent phase of the life cycle of the organism. It is the age of senescence, and all the various processes of

aging are seen. Sclerotic vascular changes make their appearance, as well as other degenerative changes in the viscera, the skeleton, and the external structures of the body.

On the psychologic level there frequently occurs a profound reorientation of the woman's attitude toward her environment. Psychologic disturbances ranging from the psychoneuroses to the psychoses, of which involuntional melancholia is an important example, make their appearance. Thus, it is a symptom complex in which psychologic, glandular, and other somatic changes participate, and any approach that pretends to completeness must bear all these factors in mind.

What brings the menopause about appears to be the gradual aging of the ovary which, as a result, becomes more and more resistant to the normal sequence of stimuli that bring about the menstrual cycle. This quiescence of ovarian activity is, of course, part of the normal sequence of events, and in the majority of women adjustment is adequate. About one-third of the women fail to make this adjustment, and a number of unpleasant symptoms, grouped under the term "menopausal syndrome," result.

There have been several hypotheses offered to explain the genesis of this syndrome. It has been suggested that these symptoms arise from the excessive production of the pituitary gonadotropic hormone, which acts to produce vasomotor and other disturbances. Another hypothesis is that the symptoms are a consequence of the lowered estrogen production. Neither of these hypotheses, to my mind, explains the etiology of the menopause syndrome, since there is no difference with respect to the amount of estrogenic hormone or urinary gonadotropic hormone in women with and without symptoms. There is nothing known with certainty of the factors that make one woman react so badly to these hormonal

changes and another adjust harmoniously, but it is becoming rather generally recognized that it is a psychobiologic problem in which the stability of the total personality is an important determinant. In this discussion I shall confine myself to a consideration of the hormonal aspects of the therapy of the menopause.

Before passing on to the specific treatment, I should like to stress the importance of this age period for the development of neoplasms. The climacteric, while frequently terminating quietly, is often a period of menstrual irregularity, both with regard to periodicity and flow. Every effort should be made with the help of the gynecologist to make sure that these irregularities are not associated with pathologic changes in the pelvic organs. Before initiating any hormonal therapy, it is wise to correct any inflammatory changes such as those so frequently found in the cervix and which may predispose to the development of carcinoma. The necessity for such precautions cannot be overemphasized.

There is almost no syndrome that is as bizarre and extensive as the menopausal syndrome. Certain classic symptoms are recognized as characteristic, and there are, in addition, a number of atypical symptoms that seem to be specifically related to ovarian insufficiency but which occur less frequently. The most characteristic and common is the hot flush, followed frequently by drenching sweats, dizziness, palpitation, and exhaustion.

There are various disturbances of the peripheral circulation which take the form of annoying paresthesias. Asthenia is frequent. Headaches are often so severe as to render the woman quite ineffective. Insomnia, increased nervousness, irritability, and a variety of gastrointestinal symptoms appear. Arthralgias and degenerative changes in various joints contribute to the picture. Senile atrophic changes in the genital tract may produce considerable local discomfort. On the behavior level the woman tends to become distressed, emotionally unstable, irritable, and given to weeping. She is inclined to withdraw more and more into herself, feel insecure, and become hypochondriacal, resentful, and suspicious. Other psychoneurotic manifestations may make their appearance or become exaggerated. The sexual life may wane in intensity, although occasionally this period is associated with increased sexual interest. Frank psychoses may be initiated.

In dealing with the hormonal aspect of the

FIG 1

menopause syndrome we are the beneficiaries of a really remarkable advance in our chemical knowledge of the sex hormones acquired in the past decade. We are indebted to the chemists for making available a number of extremely potent estrogenic substances specifically related to the disturbances of the menopause. I have drawn on a chart (Fig 1) the formulas of the natural estrogenic hormones: estradiol, the dihydroxy estrin, estrone, the ketohydroxy estrin, and estrinol, the trihydroxy estrin. Estradiol is very likely the form in which the hormone is first elaborated by the ovary and represents the most potent estrogen. Estrone and estrinol are thought to be intermediary and degradation products, respectively, nevertheless, they possess estrogenic properties similar to estradiol. They have less activity per unit of weight, estrinol being the least active. Later on, Dr Fishman will tell you something of the character

of these intermediaries and of the relation of these three estrogens

I have also included in Fig. 1 the formula of testosterone, the most active male hormone, which, interestingly enough, has proved useful, although with definite limitations, in alleviating menopausal symptoms. Two synthetic estrogens—stilbestrol, which was synthesized by Dodds and his coworkers, and ethinyl estradiol—have also been included and will be discussed later.

Of the estrogenic hormones, estradiol and estrone are the ones most commonly used. Estradiol is usually conjugated either with benzoic or propionic acids to reduce the rate of hydrolysis in the body and so prolong its action. The use of estriol and estriol glucuronide has been almost entirely reserved for the oral route, since they have been observed to lose little of their potency by mouth in animals compared to their parenteral activity, whereas both estrone and estradiol lose a great deal of their potency (about 90 per cent) when given by mouth. However, we must not fall into error with regard to the relative efficiencies of these hormones when given by mouth. Although estriol, for example, loses little of its efficiency by mouth, its activity per unit of weight is so low that large amounts must be given orally to produce either symptomatic or estrogenic effects, and, although estradiol and estrone lose a good deal of their efficiency by mouth, full symptomatic and estrogenic effects can be achieved by taking this loss into account and adjusting the oral dosage. What one should bear in mind as the basis for the use of these hormonal preparations in the therapy of the human are the actual estrogenic requirements of the patient and the actual estrogenic activities of the preparation to be used.

At present there is considerable confusion in both these respects. With regard to the estrogenic preparations, there are a number of different units employed by different manufacturers. We are confronted with *international units* for estrone and estradiol benzoate, with *rat units* for a variety of estrone and estradiol preparations, with *day oral units* for estriol glucuronide, and with *active units* for estradiol given orally. No wonder the practitioner is confused in his choice of preparation and of dosage. Sooner or later these preparations should be standardized in terms of human activity, and such studies have been in progress in this laboratory for some time. We have found that the estradiol and estrone preparations have approximately

equivalent estrogenic activity in the human on the basis of the rat unit as determined by the biologic assay method of Allen and Dowsy, so that in substituting one for another it is safer to base such substitution on the rat unit rather than the international unit. With regard to the estriol preparations, as we would expect from the low estrogenic activity by weight, their usefulness in human therapy must await their being made available in far greater potencies than the preparations now obtainable, these have proved virtually useless in our hands.

As to the second factor, the human requirements, some progress is being made for setting up objective standards for dosage such as those available for the use of thyroid hormone in myxedema, cortical hormone in Addison's disease, and insulin in diabetes. A variety of methods exists for ascertaining, in addition to subjective symptoms, the effectiveness of estrogenic preparations. One may, for example, assay estrogenic hormone in the urine, giving enough hormone to produce the normal level of estrogens. One may obtain endometrial biopsies and look for evidence of a proliferative endometrium. One may analyze the urine for gonadotropic hormone, using as an end point the suppression of the excess excretion characteristic of the menopause. All of these procedures are time-consuming, laborious, and not free from trauma. The procedure used in this clinic is the vaginal smear method, which offers a simple and specific indicator of estrogenic activity and which may be obtained as often as desired with no trauma and trivial cost. I shall describe this method briefly.

Vaginal secretions are aspirated by means of a glass pipet to which is attached a rubber bulb, and the secretions are placed on a slide, fixed in alcohol and ether, and stained. A few photomicrographs (Figs. 2, 3, 4, and 5) illustrate a typical series of changes which takes place when a patient in the menopause is given adequate amounts of an estrogenic hormone.

The first is that of a normally menstruating woman and was obtained on the thirteenth day of the cycle at the time of the ripening of the follicle (Fig. 2). It is composed exclusively of cornified cells that are large and flat and have small pyknotic nuclei. It is virtually free of leukocytes. This is the smear produced at the height of follicular activity and represents the maximal vaginal reaction that can be obtained with estrogens.

The next example is an atrophic smear of a

FIG 2 Vaginal smear on the thirteenth day of a normal menstrual cycle just prior to ovulation. It consists almost entirely of large cornified squamous cells with small pyknotic nuclei and represents the peak of follicular activity [Illustrations from Papanicolaou and Shorr Am J Obst & Gynec 31: 806 (1936)]

FIG 3 Vaginal smear of the atrophic type from an untreated menopausal castrate. It is composed almost entirely of leukocytes and of small round or oval "deep" cells with large nuclei. These arise from the exposed basal zone of the atrophic vaginal epithelium. This picture is indicative of the absence of estrogenic activity

menopausal castrate and consists largely of small round or oval cells shed from the atrophic vaginal epithelium (Fig 3). It contains, in addition, numerous leukocytes and much debris. In the succeeding smears the sequence of changes brought about by adequate estrogenic therapy is shown. At first, there is an exudation of mucus, a disappearance of the deep cells, and a growth in the size of the epithelial cells (Fig 4), which reach the final stage (Fig 5) in which they are similar to the cornified cells seen in the smear of the normally menstruating woman at the height of follicular activity. When this stage is reached, one may be certain that the hormone has fully replaced the estrogenic deficiency and that those symptoms due to the ovarian insufficiency of the menopause should be corrected. In this way we are able to separate the true ovarian insufficiency symptoms from those symptoms of this complex syndrome which arise from other causes

and for which measures other than hormonal should be taken.

Treatment of this character must, of course, build up the endometrium in similar fashion to the estrogenic hormone elaborated by the ovary. On the cessation of such therapy, the endometrium will, if the therapy has been prolonged, break down and result in bleeding. This bleeding is of a withdrawal type from a proliferative endometrium and is not to be regarded as true menstruation. It occurs while the cells are still cornified.

Is it necessary to use the vaginal smear in the treatment of all cases of the menopause? Cannot one rely entirely on subjective symptoms? I should say that in most cases it is possible, now that we have potent preparations and some idea of dosage, to treat the menopausal syndrome without the use of the vaginal smear. But I believe that the vaginal smear helps greatly in dealing with almost any case and that it is of special value in treating

of these intermediaries and of the relation of these three estrogens

I have also included in Fig 1 the formula of testosterone, the most active male hormone, which, interestingly enough, has proved useful, although with definite limitations, in alleviating menopausal symptoms. Two synthetic estrogens—stilbestrol, which was synthesized by Dodds and his coworkers, and ethinyl estradiol—have also been included and will be discussed later.

FIG 4 Vaginal smear from the same case during estrogenic therapy. A partial effect has been obtained, with the disappearance of leukocytes and of most of the deep cells and their replacement with a larger type of epithelial cell from the growing vaginal epithelium.

FIG 5 Vaginal smear from the same case after full replacement therapy with an estrogenic hormone. It is identical with the midmenstrual smear of the normal cycle (see Fig 1) and represents the end point of estrogenic therapy in the human.

the difficult cases in which the etiology of a variety of symptoms is uncertain.

The actual regimen adopted in our Clinic is somewhat as follows. Prior to any treatment, the patient is given, in addition to a general examination, a gynecologic examination, and any pathologic difficulties such as a cervicitis are corrected. A psychologic evaluation is made so that we may ascertain what personal and psychologic problems may be contributing to the difficulty. Estrogenic hormone is then given in amounts that will produce a full follicular reaction, and the symptomatic improvement is observed at each level of smear change. The first course of treatment is given over a period of a month to five weeks, then treatment is stopped to allow the endometrium to regress and to observe the rapidity with which symptoms return. Then, if and when symptoms again warrant, that dosage which, in the previous course, brought about optimal relief is selected and given for another period of a month or so. With a patient whose uterus has

been removed, interruptions in therapy are not required but are advisable from time to time to permit an evaluation of what readjustment to the new status has been achieved. Some workers suggest a progressive diminution in dosage, a procedure aimed to hasten the readjustment, but I do not feel that readjustments are accelerated in this way and I always give an amount sufficient to keep the patient entirely comfortable.

It is interesting to compare the symptomatic response with the degree of smear change. From such a comparison it becomes obvious that women respond differently symptomatically. In terms of estrus, one woman will require eight or ten times as much estrogen as another. In terms of symptomatic response, about one-quarter of the women will lose their symptoms with relatively slight changes in the smear, another one-quarter, with moderate changes, about one-quarter, with advanced changes, and the remainder, only when full replacement therapy is brought about. The reason for

this is not clear but may be quite closely related to the fundamental psychobiologic maladjustments that to many of us appear to underlie the menopausal syndrome

Women also differ widely in the ease with which they make an adjustment to the menopausal status with hormonal therapy. With some, only a relatively short period of treatment is required, with others, therapy is required for many years. The majority falls in-between these two groups.

Let us turn again to some of the more practical aspects of the administration of estrogens. If the patient can afford oral therapy, this is by all odds the method of choice because of its convenience and the ease of maintenance of a uniform level of hormone in the organism. Otherwise, the intramuscular route is the most economic and is more usually employed. The shorter the interval between injections, the more effective the treatment with any given dosage. That is, large doses given every week are much less efficient than the same total amount given at short intervals. The topical application of estrogen in pessaries is useful for the local discomfort of vaginitis. Implantation of crystals or pellets subcutaneously has been recommended but is now regarded with less enthusiasm because of local walling-off of the pellets or crystals and the inability to control bleeding in the presence of the uterus. In giving oral therapy, one must bear in mind that at least ten to twenty times the effective parenteral dose of estradiol and estrone must be given to produce an equivalent effect. One such preparation is labeled in active units, which represent 10 per cent of the actual number of rat units in the preparation, so as to provide for this loss of activity. All oral, estrogenic preparations should be similarly labeled.

Because of the variability from patient to patient, each patient must be regarded as an individual problem. About 2,000 rat units of estrone or estradiol benzoate, intramuscularly, three times a week, will probably be reasonably effective in dealing with the menopausal symptoms of the average patient and may be used as a trial dosage subject to modification in the light of the needs of the individual patient.

In addition to the estrogens, other agents have been employed in the treatment of the menopausal syndrome. Testosterone propionate has also been found to relieve symptoms, but because of the production of undesirable effects, such as hirsutism, deepening

of the voice, and enlargement of the clitoris, its use in the menopause is largely of academic interest except where it may be employed temporarily for the suppression of excessive bleeding of the climacteric.

Of much more interest is a group of synthetic estrogens which has recently been elaborated. I have included the formulas of two of these in Fig 1—stilbestrol and ethinyl estradiol. They are both potent estrogens by mouth, losing little of their activity as compared to the parenteral route. The estrous unit of stilbestrol in the human is between 2 and 4 mg per day, although, as with the natural estrogens, varying degrees of amelioration of symptoms are produced with smaller amounts. With ethinyl estradiol, full estrus is generally produced with from 0.30 to 0.45 mg per day. Unfortunately, the use of these synthetic estrogens is associated with the production of unpleasant symptoms, such as nausea, vomiting, dizziness, and lassitude, in a fairly considerable percentage of patients. While the actual percentage of these side effects varies widely in the hands of different investigators, their production is agreed upon, the mechanisms by which they arise are, however, still obscure. Evidence is accumulating to show that the body is unable to metabolize the synthetic estrogens as effectively as it does the natural ones. This failure of the detoxifying mechanism would permit the synthetic compounds to accumulate in greater than physiologic concentrations, with the production of toxic effects. In the face of the present uncertainty as to the nature and significance of the side effects encountered with stilbestrol, its recent release for general use places a real responsibility on the clinician to exercise proper caution in its administration and to watch carefully for the appearance of the toxic reactions that call for its discontinuance.

I should not close this discussion without a word about carcinoma in relation to estrogenic therapy. Carcinoma can be produced in experimental animals by the use of large amounts of estrogenic hormones under certain conditions and best in animals with a constitutional predisposition to carcinoma. These doses are several hundred times those employed in therapy of the human, and they must be given for periods of time which would correspond to decades in the human life cycle. Carcinoma has never been produced in animals in the dosage range employed in human therapy. From time to time, however, carcinoma has arisen in women during or after

estrogenic therapy. Based, as it is, purely on the chronologic association of the therapy with the carcinoma, the inference that the estrogens have been causative in the cases reported appears to me to be unwarranted. The incidence of carcinoma in a large group of women treated with estrogens in our Clinic over long periods of time is no higher than that of the general population. However, as long as this question is still somewhat controversial, we should exercise every precaution to minimize the possibility of its production. We should look into the hereditary predisposition of the patient with regard to carcinoma and, as I have said earlier, subject the patient to repeated gynecologic examinations during therapy and watch the breasts carefully throughout. All inflammatory conditions in the pelvis should be corrected and excessive doses avoided.

I should also like to point out that we are dealing with a syndrome the etiology of which we do not know. We have effective therapeutic agents that are capable of alleviating the syndrome without, however, permitting us to determine the etiologic factors. There remains, once the symptoms are alleviated, the problem of the eventual readjustment to this physiologic state. To this readjustment other than hormonal factors must contribute heavily, and to this end the psychotherapeutic approach should be regarded as the most important adjunct.

DR WHEELER: I should like to ask Dr Fishman, of the Department of Biochemistry, to say a few words. He has been interested in the biochemical aspects of some of the estrogens.

DR W. H. FISHMAN: Supplementing Dr Shorr's discussion of the management of menopausal conditions, I shall consider the nature of the estrogens that are responsible for the well-known changes in the accessory sex organs of the female, particularly those of the vagina, uterus, and mammary glands.

All of the natural estrogens possess the steroid structure (see Fig. 1), a four-ringed system that is characteristic of some other important physiologic substances, such as the male sex hormones, the hormones of the adrenal cortex, and vitamin D. They are estrinol (1), estrone (2), estradiol (3), and estriol glucuronide (6). The position of the glucuronic acid residue has not yet been ascertained. All of these compounds have been isolated from human pregnancy urine, and estrone and estrinol have also been isolated from human placenta.

As Dr Shorr has pointed out, estrone and estradiol are usually injected in oily solution, and estrinol and estriol glucuronic acid are usually administered orally. A possible reason is the greater solubility of estrinol and estriol glucuronic acid in water, resulting in a more ready absorption from the intestine. Furthermore, they do not undergo so much destruction in the body as do estrone and estradiol.

The method for determining the biologic activity of these compounds now in general use is the vaginal smear technic of Allen and Doisy. As you have just heard, the cornification of the epithelial cells in the vagina is a characteristic of full estrus which occurs in the mouse every five days. When the ovaries are removed, this characteristic disappears along with the estrous cycle. After an interval following an injection of an estrogen into the ovariectomized animal, the vaginal smear may consist entirely of cornified cells. This biologic response has been standardized for quantitative work and is the assay method now most generally used by endocrinologists. The order of activity established on the basis of this procedure places estradiol first, followed by estrone, theelin or estrinol, and estrinol glucuronic acid.

However, there is confusion still existing with regard to the relative potencies of these four compounds. Many people seem to minimize the importance of estrinol and its glucuronic acid conjugate and regard the two of them as inactive excretion products of the more powerful estrogens, such as estrone and estradiol.

Recently, however, there has been another biologic response to estrogens which has been standardized for assay purposes—this is, the uterine weight increase in the immature rat upon the injection of estrogen. The standardization curves of these substances show that the effects of estradiol and estrone on uterine weight are proportional to the dose, whereas the curve for estrinol flattens out as the dosage is increased—i. e., equal increments of dosage result in progressively smaller response. Furthermore, estrinol is more effective in causing the opening of the vagina of immature rats and, unlike the other two, the administration of estrinol does not result in an accumulation of uterine fluid.

One gamma of estradiol is found to be equivalent to 6 gamma of estrinol and, by the uterine weight assay, to 20 gamma of estrone. Here then, estrinol appears to possess a greater activity than estrone in contrast to the results

obtained by investigators using the vaginal smear technic. Is the qualitative action of estrol different from estrone and estradiol? We do not know the significance of this apparent difference.

What happens to the estrogens in the body? This is somewhat of a mystery at present. A few hours after administering large amounts of estrogens to rats, minute amounts can be found in the urine and feces and hardly any in the body as a whole. Ninety per cent of the estrogen injected into the blood stream of a dog disappears within a few minutes after injection, and only 13 per cent can be recovered in the urine. From this it appears, therefore, that the body possesses a low capacity to store these estrogens and they are readily inactivated. Is this inactivation process brought about by the conjugation with glucuronic acid and subsequent excretion of estrogen or may it not be direct destruction of estrogen? How important is the liver in this inactivation?

The metabolism of estrogen during pregnancy pursues an interesting course and one that is different from the estrogenic picture in the nonpregnant woman. Cohen and Marman found that at about the eighth to the ninth month of pregnancy as much as 20 to 25 mg. of estrol is excreted per day and that 99 per cent of this is in a combined form. The amount of free estrogen in the urine is low, approximately 1 per cent of the total. The total amount of combined estrogen excreted in the urine mounts up month by month until after eight and one-half months have passed. At this time there is a sudden rise in the amount of free estrogen excreted and a corresponding fall of that which is in the combined form. It has been suggested that this sudden liberation of free estrogen sensitizes the uterus to the oxytocic principle of the posterior pituitary and results in the initiation of the first stages of labor. Whatever the explanation, the mechanisms that govern the conversion of combined estrogen to free estrogen may prove to be fundamentally important.

Of the synthetic estrogens that Dr Shorr mentioned, stilbestrol is the familiar one, and it has two to three times the potency of estrone. It is more effective orally than estrone or estradiol. Superficially, it would appear inconceivable that this compound could lead in the body to the formation of the four-ringed cyclopentanophenanthrene nucleus that we find in estrone, but there is a structural similarity between these which is

evident when the formula for stilbestrol is written as in No. 8 and compared with No. 2 in Fig. 1. It is interesting to note that compound No. 9, which is stilbestrol with the rings closed, is effective in producing estrus but that large amounts are required to do so. Another estrogen that has been recently synthesized is ethinyl estradiol (7). This compound has a greater oral and subcutaneous activity than any of the naturally occurring estrogens. It is conceivable, therefore, that this compound may lead to the formation of estrogens in the body. It must be admitted, however, that our knowledge of the metabolism and mode of action of the synthetic estrogens, as with the naturally occurring estrogens, is meager, indeed.

DR. WHEELER: Dr Javert, I wonder if you would say a word from the point of view of the Department of Obstetrics and Gynecology on this subject?

DR. CARL T. JAVERT: I should like briefly to state the point of view of the Department of Gynecology regarding the menopause as Dr Stander teaches it. The menopause is fraught with complications from time to time. The patient usually consults us because of a deranged menstrual function, and that derangement may be either an amenorrhea or scanty menses or an increased flow. Before the patients come to us many of them have had a certain amount of endocrine therapy. This therapy may have been oral, intramuscular or in the form of vaginal suppositories. In the group that has amenorrhea, this form of therapy may have been beneficial, especially following a surgical castration with sudden cessation of the menses. However, not infrequently, when we perform the gynecologic examination that Dr Shorr has stressed repeatedly, we find that the patient is pregnant. We have had several patients recently who had received large quantities of endocrine therapy and were pregnant. These patients may have had amenorrhea longer than the period of gestation, thereby confusing the picture.

Another group has received radiation which has produced an amenorrhea and, because of the amenorrhea, they in turn have received a certain amount of hormonal therapy. I can remember several cases with hematometra resulting probably from the restimulation of the lining of the uterus.

In the group with scanty menses or surgical menopause, the hormonal therapy has done the greatest good. Here the hot flush, the vasomotor symptomatology, has apparently

been benefited. I do not base this remark on any study of cases, but it is the impression I have and you can take it for what it is worth. However, in this group we have the obese patient and the hypertensive woman, and it is thought that in addition to the hormonal therapy additional benefit might be derived from attention to either or both of these associated conditions. Many of the women in the menopause are obese and a large percentage of them do have hypertension.

Of the patients with profuse periods or increased flow, not a few have had endocrine therapy for six months or a year without a pelvic examination, and it is in this group that the gynecologist finds cases that create despair, for, not infrequently, carcinoma of the body of the fundus or carcinoma of the cervix is uncovered. Six months or a year or even two years have elapsed when other therapy could have been instituted. Here again, Dr Shorr has commented in regard to the importance of the gynecologic examination. I am glad he said *repeated* gynecologic examinations during the course of endocrine therapy. It is common in the taking of the history of these patients to learn that the doctor did not make a pelvic examination. That is the case even in the City of New York and in many other large cities. Carcinoma of the cervix or fundus has been the biggest bugbear, as far as the gynecologic department is concerned, when hormonal therapy is used during the menopause.

Among the causes of increased flow at, or after, the menopause, strangely enough, we find hyperplasia of the endometrium. Why hyperplasia should be associated with the menopause when hormonal function is presumably at a lower threshold is not clearly understood. Hyperplasia has been reported up to the seventieth year of life. In fact, Novak takes the view that it may be a precursor of endometrial carcinoma. Whether that is true or not remains to be seen. I saw a case recently that had been in the menopause for a year, and curettage was done because of postmenopausal spotting, she had hyperplasia of the endometrium. Of course, in other cases the spotting and increased bleeding may also be due to a senile endometrium. Dr Shorr's presentation is admirable. From the standpoint of the gynecologic department it is especially so, since he points out that these patients require careful and repeated gynecologic examinations.

DR WHEELER: Thank you, Dr Javert.

I should like to ask Dr Shorr to say a word

about the choice of preparations. There is a huge variety of proprietary preparations of the endocrines on the market, and it would be desirable to know which are the good ones and which are the bad. Also, it would be useful to have a few more words, Dr Shorr, about the average doses required as a guide to the amounts needed in starting therapy.

DR SHORR: In answer to Dr Wheeler's question as to the choice of medication, there is one general rule as to what not to use in the way of estrogenic preparations. These are all the various dried ovarian residues, glycerol extracts of the ovary, and watery ovarian extracts. These hangovers from the dim dark past of endocrinology are, of course, utterly useless and should be abandoned. The preparation of the active estrogens that are available commercially fall into several groups. There are the estradiol preparations, which consist of either estradiol or of estradiol conjugated with benzoic or propionic acids. Free estradiol is intended for oral administration, the conjugated forms for intramuscular use. Estrone is available in either a crystalline form or a highly purified state for intramuscular or oral use. There are, likewise, an increasing number of preparations that owe their activity almost entirely to estrone but in which no effort has been made to separate it from the other estrogens, such as equilin and equilenin, which occur in stallion or pregnant mares' urine, which is its source. Estradiol and estrone are also available in pessaries and ointments for local use. Estriol and estriol glucuronide are intended for oral use exclusively. It is hoped that they will ultimately be made available in sufficient concentrations so that they will be useful in human therapy. As I said before, the chief considerations with respect to the choice of hormones are the actual estrogenic activity of the preparation, of which the rat unit is a better standard of reference for the human than the international unit, and, of course, the reliability of the manufacturer. The present powers of the Food and Drug Administration are such as to insure the maintenance of rigid standards for these products.

As to the question that Dr Wheeler asked about the average dosage required, I have touched on that previously. It is an individual problem with each patient. With some patients 1,000 rat units a day produce a full estrous reaction, in others, 10,000 rat units a day are required. This indicates the wide difference in response which we encounter. As a starting dosage I should like to suggest

approximately 2,000 rat units, intramuscularly, three times a week, and then adjusting the dosage in terms of the response. If the expected therapeutic response with this or higher doses is not achieved, the vaginal smear can then be used to ascertain the reasons for it.

Summary

Dr SHORR You have listened to a discussion of what is perhaps one of the most satisfactory chapters of present-day endocrinology. Clinicians have become increasingly aware of the variety of symptoms which may arise from the menopausal maladjustment and which can become a source of profound distress not to the patient alone but also to those who make up her world. As the result of one of the most brilliant achievements of modern chemistry, powerful and effective estrogenic agents have become available for the amelioration of this distressing condition. Indeed, a start has already been made toward the synthesis of inexpensive, actively estrogenic substances, a fascinating chapter that Dr Fishman has briefly touched upon. Furthermore, methods have been developed for the controlled therapeutic use of these hormones which compare favorably in accuracy with those employed in dealing with other ductless glandular systems.

The practitioner has not been slow to take advantage of this therapeutic opportunity. But he has been confused by the number of different estrogenic preparations, each with its own unitage based on any one of a variety of methods of assay on animals. He may take comfort from the growing awareness that the human is the most appropriate test object for the assay of these different estrogenic agents and that the method for such assays is already available in the vaginal smear. He can, till then, accept the rat unit as the more reliable index of the comparative activity of different estrogenic preparations. When estrogenic preparations are employed by mouth, he should provide for the loss of 90 to 95 per cent of the activity of natural estrogens by this route.

The swift symptomatic relief from estrogenic hormones in the menopause should, however, not lead to the neglect of the many organic concomitants of this age period. Dr Javert has properly emphasized the danger of overlooking possible pelvic abnormalities at an age period with the highest incidence of carcinoma of the uterus. And, while there is no proof that the use of estrogens leads to neocarcinogenesis in humans as it does in animals, this does not relieve the physician of the responsibility for making repeated examinations of the breasts and for exercising special caution in patients with a familial history of carcinoma.

Another prevalent tendency is to hold the menopause responsible for all the disturbances encountered at this period. It is safer to regard the climacteric as only one episode in the more inclusive process of aging and to differentiate those phenomena that are specifically hormonal from those of other origins for which other types of treatment are appropriate. This is readily done by instituting full replacement therapy as indicated by vaginal smears and noting those phenomena that fail to respond to treatment.

The possession of an effective therapeutic agent for any condition often has the undesirable effect of diminishing our concern for the less immediately pressing, but often more fundamental, aspects that still remain obscure. I have pointed out how little is known of the mechanisms by which the menopausal syndrome arises and have had to confess that our concept of the process of readjustment consists of mere verbalization. What can be said with certainty is that the menopausal adjustment is not a purely hormonal matter but is dependent on more fundamental characteristics of the individual. The quality of the previous personality adjustment to the life situation appears to be a major determinant of the ease or difficulty with which the menopausal adjustment is made. Such considerations serve to point out the increasingly important role that psychotherapy can be expected to assume not only in the treatment but also the prevention of this condition.

OLD-FASHIONED

The marriage rate is rising nowadays! Though weapons are improved in many ways, Dan Cupid's doing well, we're glad to know, With just a simple arrow and a bow—*Gerald Raftery in the New York Sun, September 29, 1941*

WHAT'S THAT? SAY IT AGAIN

Did you ever stop to think how much better it is to be well and think how much better it is to be well than it is to be sick than it is to be sick and think how much better it is to be well than it is to be sick?
—Adapted

Mental Health

In the Salmon Lectures delivered at The New York Academy of Medicine last month, Dr Robert Dick Gillespie, psychiatric specialist of the Royal Air Force, told of the rare instances of mental breakdowns among the fliers and the phenomenal ability of the English civilian to withstand his present life. Résumés of his addresses are given below—Editor

Mental Breakdowns in Army Avoided by Strict Tests

HOW the United States may avoid mental breakdowns among its armed forces by strict mental and physical examination before induction was described by Dr Gillespie in his first lecture.

"There are remarkably few cases of psychoneuroses among the members of the Royal Air Force, and this is largely due to the extreme care which is used in selecting them. Only the mentally and emotionally stable get past the weeding out process which precedes acceptance into the RAF.

"Moreover, everyone who flies for the RAF and most of the ground force has the 'professional attitude' toward his work, whether he is a pilot or an air gunner, a mechanic or a rigger. His patriotic devotion is reinforced by his pride in his particular technique and his devotion to his job."

As an illustration of the rarity of psychoneuroses among the RAF, Dr Gillespie pointed out that a hospital specially built for the care of psychoneurotic victims in the RAF had to be closed down after a few months and directed to other purposes because there were not enough patients to keep it going.

"One reason why there are fewer neurotics in this war than in the last is the greater importance which is attached to the individual. Even among the infantry today, a man tends to be more and more a technician and less of a foot flogger."

Another class among which psychoneuroses are virtually unknown is the medical profession. Dr Gillespie attributed this phenomenon to the fact that doctors also have a "professional attitude" toward work, because they have a great responsibility to others and have had a realistic education.

"Surprisingly enough," Dr Gillespie continued, "the war has given birth to two institutions which are highly successful as a preventive of psychoneuroses."

Emphasizing the social aspect of psychoneuroses, which he defined as "a social disorder of the individual," Dr Gillespie said, "We have learned that shelter life with its common sharing of danger has helped people to withstand peril better than isolation in small groups, which often contributes to the development of psychoneuroses. The feeling of being with others during an air raid, even in an insecure shelter, brings courage."

"Moreover, shelter life and community centers fill a need for companionship and entertainment which were hitherto unmet. In large cities before the war we had the paradox of want amid plenty, social want in the midst of social possibilities."

"Now we find persons returning from safe areas to the shelters in large cities declaring 'I'd rather be bombed than bored.'"

Dr Gillespie named as one of the most signifi-

cant symptoms of psychoneuroses the apathy noted in the battle-worn soldier as well as in those whose homes have been destroyed and whose lives are completely disorganized.

"I believe that this apathy is a modern equivalent of the passive acceptance or lethargic state known in the Middle Ages as 'accidie' and that psychiatry has tended to overlook its existence because the symptoms are negative rather than positive. This apathy is usually the result of the continual thwarting of simple desires—in the case of the soldier, the repeated thwarting of the instinct of self-preservation, in the case of the civilian, the thwarting of the desire for activity."

"Activity of some sort is a necessary condition of happiness and for many people a necessary preventive of psychoneurotic or antisocial behavior. It is important for psychiatrists to recognize the apathy or restlessness which may precede psychoneuroses or antisocial acts."

In wartime, he pointed out, this apathy often precedes symptoms of psychoneuroses among soldiers and fliers. Or else the continual thwarting of the desire for activity produces restlessness and irritability followed by rebellion.

"The organism that is not active is halfway to death," Dr Gillespie reminded his listeners. "After the war we may expect either a dangerous restlessness or an equally dangerous apathy unless we are as energetic in organizing peace as we have been in organizing war."

"For it is possible that if the psychiatrist had extended his observations to the preclinical changes, he might have been more useful in warning politicians of the threat to civilization contained in the thwarting of the activity instinct in such large sections of the world's population, leading in one country and one time to the symptom of apathy, at another to delinquency on an international scale."

Dr Gillespie considers the economic background of the individual a major influence in the development of psychoneuroses. In the poorest families, he pointed out, there are the smallest number of psychoneurotic cases. If the psychological conditions in the home are good, even extreme poverty leaves children unaffected.

Much more important than money in preventing the development of future psychoneuroses in children, Dr Gillespie believes, is the cultural or family background. Emotional security is the central need of children in a family. Parental rejection of children is as potent a cause of neurosis as divagations of the libido.

"Contrary to expectations, we have found in London that several families consisting of evacuated mothers with their children can live harmoniously in one house. The anticipated crises do not arise. This method works out much better for the children than when they are placed in the care of women other than their mothers,"

no matter how complete is the care these women give them.

"Among children," he continued, "we have found that delinquency is often the opposite of psychoneuroses. In many cases, if a child had not been delinquent, it would have become neurotic."

It is only when psychiatrists reach the middle-class "competitive society in their observations that they find psychoneuroses becoming much more numerous, since competition seems to breed the desire for power, and this desire when unsatisfied breeds the beginnings of psychoneuroses."

Dr Gillespie blamed this destructive desire for power on the values inculcated by the more expensive types of education, which do not protect students from neuroses. The values from the cheapest forms of education he called inadequate.

"The poorest people lack 'pivotal' or fundamental values," he said, "and have instead superficial interests which are dictated largely by the cheaper newspapers."

Significant findings on the relation of unemployment to psychoneuroses have been made, Dr Gillespie revealed. From their observations, he said, psychiatrists have concluded that unemployment is less likely to produce psychoneuroses in men than in their wives, who are more inclined to develop anxiety neuroses from financial worry than men.

Women, however, do not seem to crave employment for its own sake, since studies show that women who are employed outside the home are less happy and contented than women who are living at home and are unemployed.

In his lecture, Dr Gillespie defined psychoneuroses as "abnormal mental states showing bodily or mental symptoms and resulting from a conflict over personal relationships."

Differentiating between the psychoneurotic and the psychotic states, Dr Gillespie pointed out that "unlike the psychotic victim who views the world with delusions and hallucinations the psychoneurotic patient has the same outlook as the normal man. It is believed that the psychoneurotic and the psychotic states are different degrees of intensity of reaction of the same mind to stress. A patient may at one time exhibit psychoneurotic symptoms and at another time psychotic reactions."

"Those who are most apt to develop psychoneuroses during war are those who in childhood exhibited morbid fears and 'nervousness' or those who have an obsessional, conscientious personality, particularly when overworked."

"While most mental disturbances are departures from a previous normality for the individual, others are the individual who may be subject to episodic disturbances, which for him are the only actual 'disease.'"

Civilian Population Suffers Small Psychological Damage

THE outstanding phenomenon of the present War has been the ability of the English civilian population to withstand constant air bombardment, loss of home, and disruption of their daily routine without suffering appreciable psychological damage. Not only have the storekeepers of London and elsewhere done "business as usual," but studies have indicated that there were actually fewer days lost by salespeople and other workers in bombed areas during the period of the "blitz" than in normal times. Dr Gillespie cited figures showing that in seventeen stores in the London area, while there were 687 days lost by employees in 1939, during a period of heavy air bombardment in 1940-1941, for a comparable period, there were only 673 days lost.

In the east Anglian area a similar condition was found with absenteeism being reduced from 4.1 days per employee to 3.1 per employee during the period of heaviest attack, which he stated was typical of the rest of England.

In this connection he said, "In general the decrease in absenteeism in the aggregate and per person employed is marked. Over this whole area it decreased by one day per person taking the area as a whole. The only month in which there was an absolute increase was in July before the bad air raids started but at that time there were a good many night alerts and the girls were very tired by staying up through the whole period of the alert."

"It can be said that one of the most striking things about the effects of the war on the civilian population has been the relative rarity of pathological mental disturbances among the civilians exposed to air raids. Guy's Hospital which is situated in Southwark—the Southwark of the

Canterbury Tales and of John Harvard—is in the middle of one of the most frequently bombed areas of London, and in the midst of a large population area of the poorer classes. Yet the psychiatric outpatient department which still functions there, records very few cases of neuroses attributable to war conditions. The patients who do come, with few exceptions, present mainly the same problems as in peacetime.

"As regards any significant sex difference in the development of psychological reactions to bombing, the difference seems to be in favor of women rather than men among the civilians. The male cases of emotional shock and psychoneuroses resulting from air raids in the Guy's sector comprises South East London and the whole Kent, which has been the area probably of the greatest and most continuous exposure."

Children, generally speaking, take their pattern of behavior from the adults and, if a brave demeanor was shown, children automatically followed suit. However, with children as with adults, more important than fear of death or destruction is the importance of satisfying their everyday needs. "It is not the physical danger or the prospect of it that matters most," Dr Gillespie said. "The outstanding lesson learned, not without surprise during recent experience, is that war or no war the pressing needs of parents with problem children cannot be ignored. Increasing demands for help coming from parents during recent weeks indicate that anxiety regarding their children's day-to-day difficulties takes precedence even in these times over the remote fear of death and destruction." Behavior problems arising in children are usually caused by environmental or domestic situations, as in

peacetime, and can rarely be traced directly to the impact of the war itself. Dr. Gillespie asserted, although there were several instances where a behavior problem was aggravated by a fear of air raids. In many instances the absence of one or both parents, in the service of munitions, played an important role.

Concluding this point, Dr. Gillespie said, "Children are then remarkably unaffected by fear of air raids and this is undoubtedly connected with behavior of the adults around them. It is recorded, for example, that in a children's ward of a general hospital nurses set an example of cool courage by carrying little patients to shelter, and sitting up with them all night. None of the children whimpered, some fell asleep in the middle of the bombardment. Some of them indulge in games representing an air raid and may work off whatever anxiety they have in this way."

"I have had difficulty in collecting instances of 'bomb fright' among children. No acute emotional reactions among children have been seen in Guy's Hospital," Dr. Gillespie said.

Several children have suffered from "siren fright," i. e., from symptoms associated with the sound of sirens, but these particular cases occurred in children who had not actually been subjected to bombing itself, and who had previously shown some evidence of psychoneurotic tendencies.

When psychological trauma is suffered during a bomb raid, Dr. Gillespie stated, it might assume any one of a variety of forms, most immediate being "acute panic," some confusion, and loss of memory for what has actually happened, particularly if the individual has left his post of duty. Acute panic occurs, however, only in the predisposed, especially the habitually timid and anxious.

The second type of immediate reaction to bombing is the immobility or passive reaction. For example, a young married woman who had always been timid and shy, and inclined to tremble in talking to strangers, heard the warning siren and made for a shelter, some bombs dropped before she reached it, and she hesitated before entering, and then apparently became unconscious. On recovering in the hospital she said she had lost the use of her legs.

A third type of immediate reaction consists in direct bodily manifestations of fear, tremor, dilated pupils, staring eyes, and such transient reactions as weakness of the legs.

In addition to psychological reactions observed at the immediate scene of the bombing, Dr. Gillespie pointed out that more frequently there were remote reactions, which develop after a period of time. He cited the case of a young woman who had been in a building which had been smashed in a bomb raid and showed hysterical aphonia (inability to talk) for a week afterward. The reason for this reaction, he said, was because her mouth became filled with brick dust immediately after the explosion and she had found difficulty in speaking.

"All such conditions occur as a rule only in the predisposed," Dr. Gillespie stated, "but exceptions to this rule are those who have been repeatedly exposed to frightening experiences and those who have undergone even more than usually terrifying ordeals."

More spectacular, and unexpected, than any of these reactions, Dr. Gillespie emphasized, was

the frequency with which individuals whose entire life had previously been characterized by timidity, shyness, or other psychoneurotic manifestations were transformed into outstandingly courageous and self-sacrificing persons.

Typical of this group was the case cited of a 24-year-old dental mechanic who had been receiving medical attention for four years suffering from a depression in a timid personality. He dated his condition of "nerves," as he called it, to an air raid when aged four in the last war. He was very small in stature and had always been self-conscious about his size. He had found the greatest difficulty in making an impression anywhere on anyone, unsuccessful attempts to learn dancing, for example, and other social failures aggravated his depression of spirits. He dreaded being handed a rifle, and before the attack on London began he dreaded to face work with casualties. He was considered unfit for the fighting services and was finally assigned to A. R. P. work. Anyone who saw him would have marked him as a miserable little shrimp and no future hero—but he became very successful as an A. R. P. warden. According to Dr. Gillespie, "he has had at least three remarkable escapes and received a bomb splinter in one hand. He remarked that in critical moments 'girls turn to me'." He liked to see the planes coming. "It is my quickness," he said, "against theirs."

"In 1940 he was bombed out of his home, his mother and father were cut up and shocked. Following this he was bombed again twice, and found that his new abode had also been destroyed. After a week's leave he went back to duty and when last heard of was in full activity, and rather aggressively critical about conditions in shelters. It is clear that he has found an opportunity which completely relieves his sense of failure and inferiority."

Some of these so-called neurotic individuals show no signs of neurosis and are efficient and courageous during a bombing but develop acute signs of anxiety again only when released from duty and posted to a quiet place.

Dr. Gillespie stressed the fact that keeping people busy and occupied was one of the best ways of preventing mental breakdown after facing tragedy of other terrifying experiences, thus avoiding a period of rumination which may precede a remote psychological reaction. In one survey of 119 persons in a bombed area, it was not until two or three weeks after the actual bombing that 30 per cent complained of symptoms of one sort or another, usually of bodily distress, but without evidence of physical disease. "This observation," Dr. Gillespie said, "emphasizes the importance of occupation in the prevention of psychoneurotic aftereffects. It was only after the individuals concerned had finished rearranging themselves and their affairs and had time to sit down and consider the situation that the symptoms appeared. It is disorganization rather than fright that is the causal factor here."

Dr. Gillespie discussed at some length the problems associated with the transplanting of thousands of evacuee children and said that while some personality difficulties were noticed "children adapt themselves far more readily to new persons and new environments than had generally been predicted."

In commenting on an increase in juvenile delinquency, he said, "It has to be remembered that although the removal of many of the outlets that ordinarily exist in a city plays a considerable part in sending up the juvenile delinquency, on the other hand, those who moved to the country find new interests and probably better ones than they ever did in town. One group of boys evacuated from London to the country have actually lost their interest in cricket to a large extent and become enthusiastic about hay making and work on the farm as well as other country pursuits. It is an interesting object lesson for the future use of the energy of the young and also suggests possible lines of reorientation of their values."

A general survey of evacuee children, Dr Gillespie said, indicated that there had been no great increase in psychological disturbances and that the majority of those who exhibited them had presented problems also before the war. Analysis of a group of children who had evidenced behavior problems after evacuation indicated that in 10 per cent of the cases the new foster home was unsuitable, in 19 per cent the parents of the child, either because of ignorance or selfishness, were the disturbing factor, and that in the remainder the difficulty was caused by some personality or intellectual difficulty such as feeble-mindedness, physical defect, or bad behavior patterns which pre-existed.

Disorganization of the child's regular routine is the most devastating factor of all, Dr Gillespie said, and seems to have occurred as frequently

in children who had not been evacuated but whose school hours had been curtailed and whose recreational clubs are no longer open as a result of air raids.

Most successful placements of evacuee children are working-class homes where the evacuee "lumps in" with the rest, "even with the problem children." "These women show a patience which is often lacking elsewhere in big houses and with richer people, and the only successful way is to have a group of five or six children with a helper. Otherwise the child is apt to fall between the owners and the maids, neither of whom feel themselves fully responsible for its entertainment. This leads to wandering about in the streets and getting into mischief."

He indicated, in conclusion, that British authorities were readapting themselves to facts as they became known and were aware that the re-establishment of homes after bombings was as important as hospital treatment for the maintenance of good mental health, that the problems arising out of the evacuation of children were being studied and more attention was now being given to be certain that the home and the child were mutually adaptable, that psychoneurotic reactions following exposure to danger were much less frequent than was to be expected and apparently no greater hazard than the disorganization of life for the individual as a result of conditions in a bombed area or of evacuation to strange districts, where habit patterns suddenly were uprooted.

MENTAL HEALTH AND THE GENERAL PRACTITIONER

Urging the adoption of a comprehensive program for civilian mental health, Mr. Watson B. Miller, Assistant Federal Security Administrator, recently addressed a group of psychiatrists, according to the *Annals of the District of Columbia*. He stated that "psychiatric knowledge already far outstrips its application. Much more can be learned, and will be learned as greater attention is paid to research in nervous and mental diseases. Psychiatry in the United States is far more advanced than in any other country. Yet there are in the United States today only 3,000 trained psychiatrists."

"What is more disturbing, medical education has not equipped general practitioners to recognize mental disease in its early stages, nor to apply psychiatry in the treatment of a very large number of their patients whose bodily ailments are clearly psychic in origin. Yet, it is impossible to see how we can make further progress in mental hygiene without the informed interest of the general practitioner. It is he who first sees the great majority of incipient cases, it is he to whom the neurotics turn with their subjective symptoms, very real to them, for which he can find no demonstrable physical cause."

"Not only the major share of case-finding but even a part of treatment can be done by the well-trained general practitioner. The psychiatrist should be regarded as the consultant and the specialist in the treatment of mental disease."

YESTERDAY, TODAY, AND TOMORROW

There are two days in every week about which we should not worry—two days which should be kept free from fear and apprehension.

One of these days is yesterday with its mistakes and cares, its aches and pains, its faults and blunders. Yesterday has passed forever beyond our control.

All the money in the world cannot bring back yesterday. We cannot undo a single act we performed, we cannot erase a single word we said. Yesterday is gone.

The other day we should not worry about is tomorrow with its possible adversities, its burdens, its large promise and poor performance. Tomorrow also is beyond our immediate control.

Tomorrow's sun will rise either in splendor or behind a mask of clouds—but it will rise. Until it does, we have no stake in tomorrow, for it is as yet unborn.

That leaves only one day—today. Any man can fight the battles of just one day, any woman can carry the burdens of just one day. It is only when you and I add the burdens of those two awful eternities—yesterday and tomorrow—that we break down.

It is not the experience of today that drives men mad—it is remorse or bitterness for something which happened yesterday and the dread of what tomorrow may bring. Let us, therefore, journey but one day at a time.—L. H. P. in the *Pennsylvania Med. J.*

Medical News

Health Record for the First Nine Months of 1941

SEPTEMBER, 1941, recorded a death rate of 6.5 per 1,000, which is the lowest rate for any month in any year in the history of the Metropolitan Life Insurance Company's industrial policyholders. The first part of the year, however, owing to the influenza epidemic, registered higher rates than the corresponding months of 1940.

According to the *Bulletin* it looks as if 1941 will be among the best health years. The prognostication is based on the experience of the millions of wage earners and their dependents who are industrial policyholders of the company and

from fragmentary data for the general population. The 1941 death rate of the policyholders for the January-September period is 7.6 per 1,000, which is 1.3 per cent below the 7.7 per 1,000 of a year ago. For the general population in the 88 major cities of the United States, there have been 1,097 fewer deaths reported in the first forty weeks of this year than in the corresponding period of 1940—a decline of about 1 per cent in rate. For New York City the 1941 year-to-date rate is 9.9 per 1,000 or 2.9 per cent below the figure recorded in the same period last year which was 10.2 per cent.

County News

Albany County

At the first of a series of social justice forums sponsored by the Beth Emeth Temple in Albany, Dr. John J. Bourke, research director of the State Health Preparedness Council, spoke on the many problems of medical care and the defense program. Dr. Joseph Lawrence, executive secretary of the State Society, assisted Dr. Bourke in answering the questions of the audience.

Allegany County

At the annual meeting of the county society, held at Belmont on October 30, Dr. Herman Pearce, Jr., an instructor at Strong Memorial Hospital, Rochester, gave a talk on vascular diseases, their symptoms and treatment, illustrated with lantern slides.

The officers were re-elected as follows: Dr. William Reedy, Wellsville, president; Dr. Loren P. Bly, Cuba, vice-president; Dr. E. F. Comstock, Wellsville, secretary; and Dr. R. W. Blaisdell, Wellsville, treasurer.

Broome County

The society held its business meeting on November 11 in the auditorium of the City Hospital in Binghamton. The scientific program was postponed until two days later at the meeting of the Finger Lakes Regional Fracture Committee. Dr. Charles L. Scudder, of Boston, who has been so instrumental in the revolutionary treatment of fractures during the past twenty years, spoke on "The Operative Treatment of Fractures."

Chemung County

The regular monthly meeting of the county society was held on October 29 at the Arnot-Ogden Hospital in Elmira. The meeting was called to order by the president, Dr. George Murphy.

In the absence of Dr. A. H. Hillman, chairman, Dr. J. S. Lewis reported for the nominating committee. The committee made the following nominations: president, Dr. John Burke, Sr., and Dr. Leon Hamilton, vice-president; Dr. Swen Larson and Dr. F. S. Hassett, secretary; Dr. Harold Walker and Dr. Ross Hobler, treas-

urer; Dr. M. F. Butler and Dr. John P. Murphy, censors; Dr. F. E. Woodhouse, Dr. A. J. Westlake to succeed himself, and Dr. C. H. Erway to continue, delegate to the State Society; Dr. C. F. Leet, alternate to the State Society; Dr. J. F. Lynch requested to remain as alternate, and trustee, Dr. C. F. Abbott to succeed himself.

On Wednesday, December 10, there will be a joint meeting of the Medical and Dental societies of Chemung County, at which time Frederick S. Dunn, M.D., D.D.S., will speak.—F. S. Hassett, M.D., Secretary.

Cortland County

The members of the society are attending a series of lectures at the Cortland Hospital on Friday evenings. The next lecture will be on December 5 and the final one of the series on December 19.

Dutchess County

At the regular meeting of the society held in Poughkeepsie on November 12, Dr. Charles A. R. Connor, of New York City, talked on "Rheumatic Fever and Heart Disease." The speaker for the program was provided by the Council Committee on Public Health and Education and the Cardiac Bureau of the New York State Department of Health.

Erie County

For the best interests of his patient, the general practitioner or family physician should have equal recognition with the specialist in hospital privileges and in "medical government," Dr. Arch Walls, of Detroit, medical organization leader, told the county society on October 28.

A resolution instructing the society's committee to consider the setup of a general practitioners' unit and to report its findings at the November 25 meeting was passed.

With hospitalization insurance becoming so popular, the American Medical Association hopes "to give stimulus throughout the United States to creating a general practitioners' section in each hospital and in each medical association," Dr. Walls declared.

Dr Walls is past-president of the Wayne County Medical Society and now is president of the West Side Medical Society and the Association of Family Physicians of Wayne County and chairman of the General Practitioners' Section of Mount Carmel Mercy Hospital of Detroit.

"Right now," he said, "two-thirds of those in the profession are general practitioners. There are about 100,000 of them, as compared with 22,000 specialists and 22,000 seeking to become specialists."

"The family physician usually has to do his work in a home, even when he needs hospital facilities, or turn his work over to a specialist with hospital privileges. We know that we must have the specialist, but we also want equality."

"General practitioner sections are on trial for the following year with the A.M.A. If we can show a scientific program and satisfactory attendance, we will have equal voting power in the A.M.A. with the specialist."

The society passed a resolution providing for employment of an executive secretary. Dr Nelson W Strohm presided.

At the November meeting, held on the twenty-fifth, Dr George W Cottis, president-elect of the State Society, addressed the County Society. Dr Leonard Greenburg, director of the Division of Industrial Hygiene of the New York State Department of Health, gave a talk on industrial hygiene.

Franklin County

Twenty lectures by outstanding medical men are listed on the fall and winter programs of the Saranac Lake Medical Society and Osler Club. All sessions are held in the John Black Room of the Saranac Laboratory.

The program is as follows:

October 29 Dr David Rutstein, director of the Cardiac Bureau, New York State—"The Present Status of the Diagnosis and Treatment of Rheumatic Heart Disease"

November 5 Dr L U Gardner and Dr A. J Vorwald—"Clinical Pathological Conference"

November 12, OSLER CLUB Dr Charles C Trembley, Saranac Lake—"Recollections of a Coroner"

Friday, November 21 Dr Harold Wolff, associate professor of medicine, Cornell University, New York City—"Headache Mechanisms"

November 26 Dr J F Volker, assistant professor and Carnegie Senior Fellow in Dentistry, University of Rochester, Rochester, New York—"Radioactive Isotopes in Medical and Dental Research"

December 3, OSLER CLUB Dr Leonard Schiff, Plattsburg, New York—"Horace Nelson and His Lancet," a Saga of North Country Medicine

December 10 Dr Henry Marble, assistant surgeon, Harvard Medical School—"The Care of Infections and Injuries of the Hand"

January 7 Dr F A D Alexander, director of anesthesia, Albany Hospital, assistant professor of pharmacology and physiology, Albany Medical College—"Title to be announced"

January 14 Ray Brook Sanatorium Evening

January 21, OSLER CLUB Canon Thomas,

Late Canon in Residence, Bermuda Cathedral—"Relationship Between Religion and Medicine"

January 28 Dr Norman Plummer, assistant professor of clinical medicine, Cornell University, New York City—"Newer Chemotherapeutic Methods"

February 4 Dr William P Thompson, assistant professor of medicine, College of Physicians and Surgeons, New York City—"Hematological Aspects of Tuberculosis of the Spleen and Lymph Nodes"

February 11 Gabriels Sanatorium Evening—Dr John Hayes and Staff

Thursday, February 19 Dr C-E A Winslow, professor of public health, Yale University School of Medicine—"The History of the Germ Theory"

February 25 Veteran's Administration Hospital Evening—Sunmount, New York. Dr Siegfried Thannhauser, professor of medicine, Tuft's Medical School, Boston—"Xanthomatous Diseases"

March 4 Stonywood Sanatorium Evening—Dr Wayne L Henning and Staff

March 11 Dr Ross Golden, professor of radiology, College of Physicians and Surgeons, New York City—"The Roentgenology of Diseases of the Terminal Ileum and Cecum"

March 18 Dr Sara M Jordan, Lahey Clinic, Boston—"Practical Problems of Peptic Ulcer"

March 25, OSLER CLUB Dr George Wright, Trudeau Sanatorium—"History of Pulmonary Physiology"

April 1 Dr Melvin H. Knisely, assistant professor of anatomy, University of Chicago—"Microscopic Observations of the Circulation in Small Blood Vessels Under Normal Conditions and During Malaria and Other Diseases"

Genesee County

James A. Le Seur, former city judge, district attorney, and city attorney, was honored at a joint meeting of the Genesee County Bar Association and Genesee County Medical Society held at the Hotel Richmond in Batavia on November 5. Twenty-seven attorneys and 18 physicians paid tribute to Judge Le Seur who marked his eighty-fourth birthday on November 18.

Greater New York

To the Private Practitioners of Medicine and Superintendents of Civil Hospitals in the City of New York New Procedure Regarding the Completion of Death Certificates

Commencing November 1, 1941, private practices will be relieved of the responsibility of completing the left side of death certificates required to be filed with the Department of Health, except in those instances where the body is unrepresented by a funeral director and is delivered to representatives of the City Mortuary for burial in the City Cemetery.

This procedure was adopted by the Board of Health after approval by (1) the Public Health Relations Committee of the Academy of Medicine, (2) the Coordinating Council of the five county medical societies, (3) the Greater New York Hospital Association, and (4) the Metropolitan Funeral Directors Association.

Funeral directors will hereafter be held responsible (1) for obtaining and entering the personal

particulars required to complete items 2 to 14 of the death certificate and (2) for obtaining the signature and address of the Informant and relationship to the deceased in item 15. This change will bring procedures in New York City more nearly in conformity with practices in this regard elsewhere in the United States and will relieve physicians and hospital authorities, who frequently have little or no interest in this information, of this responsibility with which they were previously charged.

This means that with the exception of City Cemetery cases—mentioned above—physicians and hospital authorities will be required only (1) to enter the name and social security account number of the deceased in item 1, (2) to complete the Medical Certificate of Death—items 16 to 21, inclusive (and in Manhattan the Physician's Confidential Medical Report)—and (3) to fill in the Physician's Supplementary Certificate of Death by Natural Causes—on the back of the certificate, or on a separate form, *except* in connection with Form 17-H-1941, used in Manhattan only (see upper left-hand corner of certificate).

The Board of Health is confident that this change of procedure will receive unanimous approval and trusts that private practitioners and hospital authorities will renew their efforts to prepare *promptly, completely, and accurately*, the medical certificate of death and the related documents for which they are still responsible.

THOMAS J. DUFFIELD
Registrar of Records

Department of Health, City of New York
October 27, 1941

Greene County

The county society has revised the fee schedule to conform to the minimum fee schedules of the New York State Workmen's Compensation and the counties adjacent to Greene. Office visits—\$2 00, house visits—8 A.M. to 9 P.M.—\$3 00, advanced fee for night calls—9 P.M. to 8 A.M., minimum maternity including three after visits \$40 00 (does not include prenatal calls), out-of-town calls per mile or fraction thereof in addition to other charges—per mile 50 cents one way.

Jefferson County

The annual meeting of the county society was held on November 13 at the Black River Valley Club. Dr. James L. Crossley spoke on "Endocrinology in Obstetrics and Gynecology."

Kings County

At the meeting of the society and the Academy of Medicine of Brooklyn on November 18, Dr. Edwin C. Hamblen, associate professor of obstetrics and gynecology, Duke University, gave a talk on "Some Observations on the Diagnosis and Treatment of Functional Disorders of the Pituitary and Ovaries." Dr. S. Bayne-Jones, dean of the Medical School, Yale University, spoke on "Cancer Research."

Monroe

At the rededication of the Rochester Academy of Medicine Museum held on November 16, Dr. Walter B. Cannon of the Harvard Medical School gave an address. Dr. George H. Whipple

made the introductory remarks. The meeting was under the sponsorship of the Rochester Academy of Medicine, the Medical Society of the County of Monroe, and the University of Rochester School of Medicine.

Nassau County

The *Nassau Daily Review Star* carried a special health section of thirty pages in its issue of October 29. The doctors and health officers of Nassau County and the county society are to be congratulated on the well-integrated activities of the county and the splendid achievements of the various organizations.

Dr. Charles W. Martin, president of the county society, presided on October 28 at the short business meeting which followed a dinner of the group at the Garden City Hotel, Garden City.

The meeting was held in Cathedral House. Dr. Arthur C. Martin, vice-president of the cancer committee and chairman of the tumor clinic, was toastmaster. "Technical Aspects of Cancer" was the topic taken up at the scientific session, and the speakers were Dr. Fred W. Stewart of Memorial Hospital, Manhattan, Dr. Robert P. Ball of the Presbyterian Hospital, Manhattan, and Dr. Ashley W. Oughterson of the surgery department of the Yale University School of Medicine.

New York County

New York City's school authorities are co-operating with the Medical Society of the County of New York in sponsoring a series of broadcasts for school children on Thursdays at 11 45 A.M. entitled "For Your Health." The series will be broadcast over WNYC.

"These broadcasts will lay emphasis on many of the topics contained in the courses of study and syllabuses in hygiene for the elementary, junior high, and senior high schools," Superintendent of Schools Harold G. Campbell declared in a circular to school supervisors urging them to have the pupils listen in.

"Schools equipped for radio reception should, if the school program permits, make use of these broadcasting programs for classroom instruction in healthful ways of living," Dr. Campbell said. "Parents also should have their attention called to these programs," Dr. Campbell continued, adding.

"Parents and pupils through their teachers are invited to submit questions on health problems to the Medical Society of the County of New York, care of Station WNYC. These questions will be answered by the speakers who will be heard on this program each week."

Dr. Joseph Francis McCarthy, director of the Department of Urology of the New York Polyclinic Medical School and Hospital, received an unusual honor recently when a new wing in the Barros Luco Hospital in Santiago, Chile, was named for him. The entire cost of construction of the wing and equipment was covered by an endowment by Abraham Atala, a Syrian merchant. Dr. Edward Abud, a Syrian-Chilean pupil of Dr. McCarthy, presided and the ceremony was attended by President Pedro Aguirre Cerda and Claude E. Bowers, American Ambassador, who said that he felt that the entire American medical profession has been honored.

The comitia minora of the New York County Medical Society has adopted and approved a plan to provide the 4,400 tenants of the East River Housing Project, 446 East 104th Street, New York City, with the services of physicians at low cost. It is expected that the society will approve the plan after details are worked out.

The plan calls for a two-year experiment with voluntary cooperation of residents in East River houses. Residents would pay 25 cents monthly for a single person, 50 cents for a married couple, 75 cents for a family with one child, and \$1 00 a month for a family of four or more. Subscribers would receive the unlimited services of a general practitioner, one resident physician being assigned for every 250 families, or choice of any resident physician and the physician would be free to refuse a patient he deems undesirable.

It was recommended that the physicians chosen be young men who have recently completed their internship in a good general hospital. Then, if the experiment is terminated after the two years, they would have lost nothing but would have gained experience. They would be selected by a supervising medical board of outstanding physicians who are senior members of the staff of the nearest hospital.

Ontario County

During November the Geneva Academy of Medicine held its annual dinner meeting with Dr Charles B Huggins of the surgery department of the University of Chicago as the speaker. Dr Frederick J Parmenter, of Buffalo, Dr Leo Gibson of Syracuse, Dr Arthur H. Paine, of Rochester, Dr Carlyle Haines, of Sayre, Pennsylvania, Dr William Eikner, of Clifton Springs, and Dr Albert M. Crance, of Geneva, opened the discussions. All of the discussers recently heard Dr Huggins present a summary of his work at a sectional urologic meeting in Hamilton, Ontario, Canada.

Orange County

The county society has just completed, through its medical preparedness committee plans that will embrace medical problems of civilian defense for the entire county. Dr Theodores W Neumann, of Central Valley, is chairman, and members include Drs. E. G. Cuddeback, M. A. Stivers, S. B. Schleiermacher, T. D. McMena-min, and H. F. Morrison.

Oswego County

Appealing for more intensive efforts in the interest of rheumatic fever victims, whom he described as "cripples who don't lump," Dr Alexander T. Martin, clinical professor of pediatrics at Bellevue Hospital, New York University, disclosed his findings of a twenty-year study at the opening fall meeting of the county society at the Elks Club in Oswego on October 23.

A round-table discussion followed Dr Martin's talk. Approximately 30 members of the county society were present with Dr Edward Fox, of Fulton, president, presiding.

At the November 7 meeting Dr Paul Reznikoff, associate professor of clinical medicine at

Cornell Medical College, talked on the diagnosis and treatment of anemia.

Putnam County

At the regular monthly meeting at the Gypsy Trail Club in Carmel, October 1, Dr John D. Lytle, associate attending physician at Babies Hospital, New York City, was guest speaker. His subject was "Indications for Urological Investigation in Children."

The speaker for the meeting on November 5 was Dr Walter Timme, of New York City. His subject was "Status Hypoplasticus," especially in reference to its importance in examining selectees for the Army.

Rockland County

Members of the county society and the board of supervisors at a special meeting on October 22, held in Jerry's Tavern in Nyack, heard Dr Renfrew Bradner, of Warwick, unfold the Orange County plan of providing full medical and surgical care of indigent patients which has been in operation in Orange since 1935 and which he stated was operating most successfully.

Dr Bradner gave in detail the history of the system which ended in an agreement between the Orange County Board of Supervisors and the county society under which physicians who attended indigent patients received remuneration for their services on a reduced scale of fees subject to approved regulations.

Dr Harold Heller, of Spring Valley, explained that a committee of the medical society of Rockland County had made a study of the Orange County plan and was impressed by the manner in which it operated. He felt that the physicians of this county should be paid for their services, pointing out that the indigent patients and the public as a whole were inclined to the belief that in the treatment of indigents the physician's fee was paid along with other costs attending treatment of the patient.

A series of lectures being given on general medicine has three remaining meetings. They are held in the Summit Park Sanatorium in Poughkeepsie at 3 30 p.m. December 5, "Asthma," by Dr William B. Sherman, December 12, "Syphilis," by Dr Leslie P. Barker, and December 19, "The Diagnosis and Treatment of Anemia," by Dr Paul Reznikoff.

Saratoga County

All offices were re-elected at the annual meeting of the county society held on November 6 at the sanatorium of the Metropolitan Life Insurance Company, Mount McGregor. They are president, Dr Gilberto S. Pesquera, Mount McGregor, vice-president, Dr M. D. Doby, Schuylerville, secretary, Dr Malcolm J. Magon, Saratoga Springs, treasurer, Dr W. J. Maby, Mechanicville.

The society voted a \$25 donation to the iron lung fund and received annual reports. Members dined as guests of Dr William H. Ordway, sanatorium superintendent, after which they joined the Trudeau Society for the technical program.

The speaker was Dr Herman Mosenthal, professor of clinical medicine at Columbia University, whose topic was "Hypertension."

Schenectady County

Dr Charles L Brown, professor of medicine at Temple University Medical School in Philadelphia, addressed the members of the county society on November 4 at the meeting held in the auditorium of the nurses' home at Ellis Hospital, Schenectady.

The *Bulletin*, which has made its appearance this fall, is a distinct credit to the society and congratulations are due its publication committee Dr Ralph E Isabella and Dr Gomer Richards.

Schoharie County

Dr R. G. S. Dougall, of Cobleskill, was elected president of the county society at the annual meeting on October 22 in Cobleskill. Other officers named were Dr L. R. Becker, Cobleskill, vice-president, Dr Duncan Best, Middleburgh, secretary, Dr Donald Lyon, Middleburgh, treasurer, Dr Joseph Duell, Jefferson, censor, and Dr David W. Beard, Cobleskill delegate to the State Society.

Steuben County

Dr W. F. MacPherland, of Hornell, presided at a meeting of members of the county society, following a luncheon at the Hotel Wagner, Bath, on October 30. In this postgraduate program of the society, Dr W. W. Lashure, assistant professor of surgery of New York Post-Graduate Medical School, spoke on "Bursitis Strains and Sprains."

Warren County

Dr E. J. Fitzgerald, of Glens Falls, was re-elected president of the county society at the annual meeting on October 23 held in The Queensbury at Glens Falls. Dinner and a talk by Dr Robert Zollinger preceded the election. Dr Zollinger is assistant professor of surgery at Harvard Medical School. The session was attended by more than 70 physicians, including a number from Washington and Saratoga counties.

Speaking on "When Is Surgery Advisable in Peptic Ulcer?" Dr Zollinger said that the modern trend in treating the ailment and its complications is through medicine and that sur-

gery should be avoided unless a thorough trial of medical treatment fails. After the address a discussion was carried on by Drs. LeRoy J. Butler, Nelson R. Frasier, Irving R. Juster, E. B. Probasco, Lester C. Husted, and B. J. Singleton, of Glens Falls, and E. J. Callahan, of Saratoga Springs.

Dr H. H. Dier, of Lake George, was elected vice-president of the society and Dr Roger S. Mitchell was re-elected secretary and treasurer. Dr Joseph Merin, of Bolton Landing, and Drs. D. A. Zurlo and C. A. Buck, of Glens Falls, were named a board of censors, and Dr Morris Maalon was re-elected delegate to the State Society.

Westchester County

The 144th annual meeting of the county society was held on November 18 at the New York Hospital, Westchester Division, in White Plains. Dr W. W. Bauer, director of Bureau of Health Education, American Medical Association, addressed the meeting on "Health Education and the Doctor."

The Special Committee on Nominations, under the chairmanship of Dr Henry J. Vier, of White Plains, presented the following nominations for the coming year: president, Dr George C. Adie, of New Rochelle (by automatic succession from the office of president-elect), president-elect, Dr E. Christopher Wood, of White Plains, vice-president, Dr Waring Willis, of Bronxville, secretary, Dr Virgilio Minervini, of Yonkers, treasurer, Dr W. Alex Newlands, of Tarrytown, censors (two years), Dr Reginald A. Higgins, of Port Chester, Dr E. H. Huntington, of Ossining, and Dr E. Leslie Burwell, of New Rochelle, delegates (two years), Dr L. D. Redway, of Ossining, and Dr E. H. Reston, of Mount Vernon, and alternate delegates (two years), Dr R. B. Archibald, of Bedford Hills, and Dr Ralph T. B. Todd, of Tarrytown.

Yates County

A regular meeting of the Yates County Medical Society was held in Penn Yan on October 21. Dr John Lichty, assistant professor of pediatrics at the University of Rochester School of Medicine, gave the scientific paper of the evening. His subject was "Heart Murmurs in Childhood."

SULFADIAZINE IN THE TREATMENT OF PNEUMONIA

HENRY VAN ZILE HYDE, M D, Albany, New York

IF WIDE usage of sulfadiazine substantiates the predictions made on the basis of studies thus far reported, this drug may replace to a large extent other sulfonamides in the therapy of pneumonia. On preliminary study it appears to be effective in combating pneumococcal infection experimentally¹ and clinically²⁻⁵ and to be less toxic^{1,4,5,6} than its predecessors. A summary of the present knowledge concerning the drug is presented, subject to change as more information becomes available.

Effectiveness.—Animal studies indicate that sulfadiazine is effective against the beta-hemolytic streptococcus, pneumococcus, staphylococcus, and type B Friedländer bacillus.¹ The relative bacteriostatic efficacy of the several drugs has not as yet been fully determined. Clinical experience indicates, however, that sulfadiazine is probably as effective an agent as sulfapyridine and sulfathiazole in the treatment of pneumococcal pneumonia. Limited experience indicates that it is an effective agent in the treatment of pneumonia due to hemolytic streptococcus and Staphylococcus aureus.

Absorption.—Those who have studied the absorption of sulfadiazine after a single dose¹⁻⁵ are in general agreement that the drug is readily absorbed from the gastrointestinal tract, reaching peak blood concentrations in from four to eight hours, and is maintained at relatively high levels in the blood for twelve to eighteen hours after administration. Sodium sulfadiazine is readily absorbed from the subcutaneous tissues.⁴ Both sulfadiazine and its sodium salt are poorly absorbed from the rectum.⁴

Distribution in Body Fluids.—The few observations thus far reported indicate that in pleural and peritoneal fluids the drug attains concentrations about equal to those in the blood. In spinal fluid, concentrations that are about 50 to 80 per cent of those in the blood are usually attained.¹⁻⁵ During oral administration these concentrations are reached in about twenty-four hours, whereas they are reached in eight to twelve hours after intravenous administration.

Excretion.—The drug is excreted by the kidneys and is largely recovered from the urine during the period of administration and the five succeeding days. The acetylated form is excreted rapidly,^{2,4} leaving a relatively low concentration of acetyl sulfadiazine in the blood. As found in the urine, the drug is usually about one-third conjugated. Acetyl sulfadiazine is more soluble in urine than is acetyl sulfapyridine or acetyl sulfathiazole.¹

Indications.—An inclusive statement concerning indications would be premature at the pres-

ent time. Experience with the drug in various clinics warrants, however, the assertion that sulfadiazine may be used justifiably in pneumococcal pneumonia and probably in pneumonias due to hemolytic streptococcus or Staph. aureus. As experience is broadened, sulfadiazine may find a much wider field of usefulness.

Contraindications.—As with any sulfonamide compound, the contraindications to sulfadiazine therapy must always be considered in relation to the severity of the infection under treatment, the urgency of the need for sulfonamide therapy, and the availability of alternative forms of treatment. A history of serious toxic reaction to any of the drugs of the sulfonamide group and renal disease, especially in the presence of nitrogen retention, should be considered definite contraindications except under unusual circumstances. If a sulfonamide is administered in the face of suspected diminution of renal function, it is essential to follow the blood level of the drug in order to avoid dangerous accumulation within the body and to observe carefully the fluid output in order to detect immediately any tendency toward renal block. The phenosulfonphthalein excretion is a reliable index of the capacity of the kidney to excrete sulfonamides.¹²

Dosage.—Because of the low incidence of gastro reaction, it is usually possible in the adult to give an initial oral dose of 3 to 4 Gm of sulfadiazine. This is followed by 1 Gm every four hours, day and night. Since the drug is slowly excreted, 1.5 to 2 Gm. may be given at the mid-night dose, the patient being allowed to sleep for eight hours without further administration during that interval. The drug should be continued for thirty-six to forty-eight hours following apparent recovery by crisis or lysis in order to prevent recurrences. During the postfebrile period it may be given in 1-Gm. doses at six-hour intervals. On theoretic ground, it should be continued at full dosage, rather than be tapered off, because of the danger of the possible development of drug resistance on the part of the microorganisms when exposed to the low blood concentrations attained with small doses. Administration should not be continued any longer than necessary for proper control of the infection because of the danger of toxic reactions. If a recrudescence of infection occurs following interruption of treatment, the drug should be readministered in full doses, starting with 3 to 4 Gm.

In severe infections it is advisable to give an initial intravenous dose in order to reach a high blood concentration immediately.

The dosage for children¹¹ weighing 70 to 80 pounds or less, recommended for severe infections, is an initial dose of 35 to 75 mg. per kilogram ($\frac{1}{4}$ to $\frac{1}{2}$ gram per pound) of body weight, with a maintenance dose of 0.15 to 0.2 per kilogram (1 to $\frac{1}{2}$ grams per pound) per twenty-four hours. The initial dose should not exceed 5 Gm (75 grains). The twenty-four-hour dose

From the Bureau of Pneumonia Control, New York State Department of Health, Albany

I am particularly indebted to the following authorities on pneumonia for their suggestions and criticisms: Drs. Jesse G. M. Bullowa, Maxwell Finland, and Norman Plummer

is divided into four equal parts and given at six-hour intervals. This dosage usually maintains an average blood level of 8 to 12 mg per hundred cubic centimeters. After the first few days, in a patient responding well, this dose, which is relatively higher than that recommended for adults, can be reduced by one-half and given at eight-hour intervals for an additional forty-eight to seventy-two hours. In children over 70 to 80 pounds in weight, the dosage can be based on the adult schedule, with an initial dose of from 2 to 3 Gm.

Parenteral Administration—Parenteral administration should be reserved for cases in which the drug cannot readily be administered orally in full dosage and for cases in which the prompt attainment of high blood concentrations is essential. Frequent determination of the blood level should be made as a guide to dosage in cases being treated parenterally. Levels of 8 to 15 mg per hundred cubic centimeters of blood should be maintained in seriously ill patients.

Intravenous Sodium sulfadiazine may be administered intravenously in 5 per cent concentration in sterile distilled water and should be injected slowly with strict precautions against extravasation. Two and one-half to 4 Gm may be given as the initial adult dose. If the former is used, it is advisable to give a second dose of 2.5 Gm. in four to six hours. Succeeding doses must depend on the blood concentrations obtained, since there is great variation in levels in different individuals on repeated intravenous administration. Without observation of blood levels, dangerously high concentrations may be reached.

Subcutaneous Sodium sulfadiazine may be given subcutaneously in 0.5 per cent concentration in physiologic saline solution, taking one-half to one hour for the injection. Four grams in 800 to 1,000 cc of physiologic saline can be given in this way, repeated after eight to twelve hours, depending upon the blood concentrations maintained and the ability of patient to take supplementary drug by mouth.

Toxic Reactions—Although the present limited experience with sulfadiazine indicates that toxic reactions are less frequent than is the case with other sulfonamides, it has been found that the same types of reactions do occur and may be serious if not detected early and properly treated.

Gastro reactions are rare as compared with sulfapyridine and are distinctly less frequent than with sulfathiazole. Drug fever and rashes have been observed. Hematuria occurs and may be followed by anuria. It is essential to observe the urine daily for evidence of blood and to measure and record the total fluid intake and output. Carelessness due to a false sense of security in this new drug has already resulted in unfortunate and unnecessary fatalities due to renal block.

No severe blood dyscrasias have been reported as yet. The potential danger to the leukopoietic system has not been fully assayed, so that close observation and withdrawal of drug in the face of granulocytic depression are necessary in the light of present knowledge. Cases in which the admission blood count showed marked depression of the total white count but with a satisfactory percentage (40 per cent or above) of granulocytes have been treated successfully with sulfadiazine, and the white count has increased under treatment. A distinction must be made, therefore, between general leukocytic depression associated with severe infection and specific granulocytic depression due to drug toxicity. In the former, the drug is strongly indicated, in the latter, it must be withdrawn. The distinction can be made only by differential counts made before and during the administration of the drug.

In view of the limited experience with sulfadiazine it would seem hazardous at the present time to relax the vigilance with which sulfonamide patients are, or should be, observed.

The addition of sulfadiazine to the sulfonamide group does not change in any way the fundamental and generally accepted principles underlying the proper management of pneumonia. These principles emphasize the importance of the following points.

Early diagnosis and prompt institution of sulfonamide therapy.

Immediate sputum typing and blood culture.

Proper nursing care and isolation of patient.

Administration of serum in the absence of adequate response to the drug within twenty-four to forty-eight hours. It is the opinion of the majority of experts that serum should be given promptly—in addition to the drug—in patients over 50 years of age, in the presence of bacteremia, and in the treatment of pregnant women.

Medical Preparedness

NAVY PERSONNEL

REAR ADMIRAL ADOLPHUS ANDREWS, U S Navy, Commandant, Third Naval District

IT IS an unusual pleasure for me to stand here before so many physicians and dentists secure in the feeling that for once in my life I am not to be subjected to the multitude of thumpings, probings, drillings, and specimen-takings that ordinarily feature my personal relationships with the members of your professions.

I have always felt that there is nothing that puts a man on the defensive quicker than to deprive him of his clothes and then set grimly to work on his superstructure with a range finder, a listening device, and several direct hits amidships. So you can readily estimate my feeling of relief in being able to be with you officers and still retain a little more than my shirt and, also, not be forced to express my few words of greeting in competition with a dentist's drill.

As the Commandant of the Third Naval District and Commander of the newly created North Atlantic Coastal Frontier Defense responsible for both the fitness and performance of tens of thousands of Navy personnel, I cannot over-emphasize to you doctors the great importance of your work as Naval officers.

The Navy needs men. The Navy has now undertaken a mighty effort, but there is an infinitely greater and more crucial task ahead.

The number of men required for our rapidly expanding fleet is vital to the success of our entire program, but mere quantity has never been the paramount thing in our Navy and never will be. In both men and ships *quality* is that decisive factor on which depends our capacity to bring to a successful conclusion the tremendously important mission that our inspired Commander-in-Chief has given us. In this respect it is my firm conviction that the proper selection and care of Navy personnel from a medical standpoint is of equal importance with their professional qualifications.

America's dominant position on the seas of the world today rests squarely upon two fundamentals: the superior ability of each man to excel in the performance of his individual duty and our steadily increasing superiority in the finest of modern combatant ships.

We all realize that no man can do his job if he is not qualified physically and mentally, as well as professionally. The most powerful ship afloat is only as effective as the crew that mans her. After all it is the man behind the gun. If his morale is low, if his physical condition is below par, his efficiency and effectiveness will suffer in direct and dangerous proportion.

Another important contribution that the medical and dental officers make to the well-being of our Service is in the careful examination of new personnel. There is no place in the Navy for men who deviate in the slightest way from the

highest physical standards. There is a twofold and obvious reason for this. First of all, the work that our men are required to perform demands superb physical and mental equipment. No man can be depended upon to handle the intricate mechanism of a modern man of war unless he is sound both in body and mind. Second, any person on active duty who acquires a disability for which he has to be retired is subject to retirement benefits for the rest of his life. The Navy is prepared to take ample care of its disabled members, but reason tells us that any laxity on the part of examining physicians might very well create a serious situation.

No doubt you are all interested in hearing some up-to-date information on the development of our Navy. Before I give you some details of the greatest naval expansion program in history, let me advise you that at this very instant our present fleet is the most efficient fighting fleet afloat. The fleet is ready—stripped for action. In tactics, gunnery, morale, and every other factor it is superior. Our naval aviation arm is greater in both numbers and performance than that of any other navy in the world. Make no mistake about our first line of defense. This is no idle boast and is not prompted by my pride in our Service but can be stated as a simple and powerful fact.

As you may know, I have recently finished three years at sea. When I relinquished command of the scouting force of the United States Fleet, that advance unit of the Navy had undergone twenty-four months of the most extensive training exercises ever performed. It was then—and is now—ready for immediate action.

Meanwhile, we are constructing the most powerful fleet that ever sailed the seas. When completed, the United States will have 32 battleships, 18 aircraft carriers, 91 light and heavy cruisers, 36½ destroyers, and 186 submarines. This vast fleet will consist of 691 combatant vessels with 731 ships in all.

We have set the signal for "full speed ahead" to accomplish this program. Every shipyard capable of meeting our needs is operating at full capacity. Many new yards are being opened, and we are farming out widespread production contracts and constantly searching for new production units.

Sea power is as important today as it ever has been. Upon it rests our security, the fate of this Nation—with sea power this war will be won. As Admiral Thomas C. Hart so aptly said: "If unhappily our nation does have to enter into a dispute for the vital control of the seas—these seas or any other seas—I not only hope but I feel sure that you will not be hampered in the use of these seas for very long."

Personnel is one of our important problems and one in which you doctors play a particularly important part. We are enlisting men at the rate of over 10,000 per month. New training stations have been created, but this does not

An address given at a dinner of the Naval Reserve Medical and Dental Officers Association at the Naval Hospital New York City on October 29, 1941.

solve our problem entirely. Officers' schools are augmenting the United States Naval Academy so that new junior officers are being delivered to the fleet at the rate of 5,000 per year. Moreover, we have more than 12,000 Reserve officers on active duty. To man our future Navy we will need, afloat and ashore, a total of approximately 33,500 officers and 461,000 enlisted men. We now have over 200,000 enlisted men and more are coming each day.

Obviously, the medical facilities of the Navy must expand in proportion. In this respect you doctors can perform a special service to the Navy by urging your professional associates to volunteer their services just as you have. For the year starting July 1, the Third Naval District must furnish 284 new medical officers and 100 new dental officers. Encouraging progress has been made but much remains to be done, and you are the men we are counting on to do it.

Many of you have been called to active duty. Many more will be. All should be in readiness for immediate call. As Reserve officers, you have a duty to give yourself the greatest possible preparation for service. You have numerous correspondence courses and many other ways to equip yourselves so that you will be able to justify the confidence that the Navy places in you.

From long and intimate experience I am keenly aware of the great part played by the medical and dental officers of the Navy. I am delighted

that this opportunity has been presented for me to pay a well-deserved tribute to our splendid medical officers of our regular Navy and to the unselfish, enlightened patriotism that prompted you to offer your services to your country. In this critical period of the world's history, service in the Navy is service to the cause of humanity, to the cause of peace, and to the preservation of the flame of freedom to which untold generations have sacrificed their lives.

There is a particular appreciation due to men like yourselves—men trained to be leaders in your fields—because you have in many cases sacrificed far more lucrative endeavors in civil life to put your skill and experience at the call of your country. The Navy needs such help and is grateful for it. I can assure you that your return in satisfaction will be a far richer heritage.

The fate, gentlemen, of many centuries of human advancement and even of civilization itself is resting now more heavily than ever before on the guns and men of the United States Fleet. The Navy is ready, willing and able to assume this burden. Confident of the outcome and fully aware of its responsibilities, the Navy is girding itself for its mightiest effort. So to you officers, as a vital part of that Navy, I say "Stand By!" and prepare yourselves thoroughly for the work ahead. Good luck to you and many thanks for having me with you.

NEW PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS, AND VETERINARIANS

The functions of the new Procurement and Assignment Service for Physicians, Dentists, and Veterinarians, just created by the President as a part of the Office of Defense, Health, and Welfare Services, are outlined in an editorial in the *Journal of the American Medical Association* for November 8. The scope of the problems confronting the new agency also is presented in the same issue of the *Journal* in an analysis of the nation's physician requirements which reveals that, even without any sudden expansion of the Army, between 2,000 and 3,000 physicians will be needed by various governmental agencies during the next year. The seriousness of this situation can be realized when it is pointed out that approximately 5,000 physicians are graduated by medical schools each year, barely sufficient to replace the number who die annually.

The *Journal's* editorial points out that "One of the most significant actions taken by the House of Delegates at the annual session of the American Medical Association held in Cleveland in June was its approval of a resolution introduced by the Committee on Medical Preparedness urging that the United States government establish an agency for the procurement and assignment of physicians to meet the many needs arising out of the emergency in which the nation finds itself."

"On Friday, October 31, the President of the United States approved an order establishing a Procurement and Assignment Service for Physicians, Dentists, and Veterinarians as a part of the Office of Defense, Health and Welfare Services under the direction of Mr. Paul V. McNutt to stimulate voluntary enrollment of

these professions. The resolution of the House of Delegates also urged that this agency be under the direction of representatives of the civilian medical profession. The President has appointed as a board to administer the new service the following members: Chairman, Dr. Frank H. Lahey, president of the American Medical Association; Dr. Harold S. Diehl, dean of the medical school of the University of Minnesota and a member of the Education Committee of the Health and Medical Committee; Dr. James E. Paulin, who is retiring president of the American College of Physicians and chairman of the Council on Scientific Assembly of the American Medical Association and also a member of the Committee on Medical Preparedness; Dr. Harvey B. Stone, a member of the House of Delegates of the American Medical Association, of the Committee on Medical Preparedness, and of the Council on Medical Education and Hospitals; and Dr. Caleb Willard Camaher, Jr., Washington, D. C., a past-president of the American Dental Association and a member of its Committee on Medical Preparedness.

"The functions of the agency now established include primarily the procurement of personnel from existing qualified members of the professions concerned. It is proposed that various governmental and other agencies requiring professional personnel for needs related to the emergency shall send their requests to the Procurement and Assignment Service indicating the number of men desired, the time during which they must be secured, and the qualifications and limitations placed on such personnel. The Service

Nature Alone Can Synthesize the ENTIRE B COMPLEX

When you prescribe the Whole Natural B Complex preparation, Bezon, you are giving the patient the benefit of all of the 16 or more B components, not merely the few which have been chemically identified

That is but one of many reasons why Bezon has given such remarkable results in the prophylaxis and treatment of the commonly occurring B Complex deficiencies

Another important reason is that the balanced, high potency, natural vitamins found in Bezon simplify the problem of administration. One capsule provides the full daily dosage of thiamin and riboflavin together with all the other factors. If preferred, the capsule contents may be emptied into milk, cereal, etc., without destroying potencies

BEZON

MEDICAL PREPAREDNESS

[N Y State J M

[Continued from page 2358]

may then by appropriate mechanism arrange to secure lists of professional personnel available to meet these requirements, utilizing existing rosters such as the one now available in the headquarters of the American Medical Association and of the American Dental Association, or other public and private rosters which it may consider acceptable. The agency is also authorized to approach such professional personnel as are considered to be available and to use suitable means to stimulate voluntary enrollment. Emphasis should be placed on the fact that voluntary enrollment is desired and that modern means of procurement will be utilized. Already the states and many of the counties of the United States have been organized for military medical preparedness through the Committee on Medical Preparedness of the American Medical Association. Thus it becomes possible to determine availability of various physicians and their qualifications for special services. Obviously it is possible also in this way to protect the civilian needs of American communities.

"In its work the Procurement and Assignment Service is authorized to procure an executive secretary who shall serve as executive officer and who is to be a full time appointee with a salary The members of the board which administers the agency are to serve, as does the Health and Medical Committee, whose organization it parallels, without salary. The board is authorized to secure such necessary assistants as may be required, to establish advisory committees and subcommittees representing the various interests which may be concerned, to develop suitable liaison with governmental and private agencies, to establish suboffices if they are required, and indeed to do almost everything, short of compulsion, that may be useful in supplying the Army, the Navy, the Public Health Service, essential industries and the civilian population with necessary professional personnel.

"Recently the *Journal* called attention to the problem created by failure of junior and senior medical students and of interns to avail themselves of the opportunities offered by the Army and Navy medical departments to become enrolled in official agencies which would make them available when called as commissioned medical officers. No doubt the new Procurement and Assignment Service will give special consideration to this phase of the problem. From the reservoir of young physicians coming into the practice of those medicine must be obtained the majority of those needed for replacement of physicians now in service as members of the reserve corps. Should there be a sudden large expansion of our army, the number of physicians needed might approach ten thousand or more. The securing of these men could be brought about without jeopardizing the health of the nation by utilizing the complete cooperation of the medical profession."

In the Medical Preparedness Section of the same issue of the *Journal* appears an analysis of

the present situation as regards the supply of physicians in the present emergency. Pointing out that the officers in the Medical Department of the Army today include 11,465 physicians in the Medical Corps, of whom 8,983 are Reserve officers, 1,250 regular officers and 1,232 National Guard officers, the *Journal* says that "there is at present a shortage of 1,473 medical officers. Should the Army not be greatly expanded within the next year but continue with a training program of about the present scope, a maximum of approximately 3,200 replacements would be required each year for the next five years during the period of the Selective Service Act. It is estimated that approximately two-thirds of the physicians now in service would elect to remain for the period of the emergency. If, however, it should not be possible to retain these men in service, the number needed for replacement would be considerably expanded."

In the Navy approximately 100 physicians are required at the present time as replacements and it appears that with the expansion now in prospect another 700 would be required by next July. To meet this need the Navy has a pool of 1,000 in its Reserve Corps. The calling up of these men obviously would reduce the number of physicians available for civilian and nonmilitary needs.

The United States Public Health Service requires about 35 new officers each year to meet its normal requirements for replacements, but in view of the present expanded activities approximately 100 interns in public health service institutions will be required within the next year. In addition, state health departments require about 150 additional physicians to meet new expansions.

The United States Veterans' Bureau now has about 1,800 physicians in full-time positions, about 500 of whom are in the United States Army Medical Reserve Corps. These 500 will require replacement if they resign their commissions in the Reserve Corps or if they elect to accept active duty with the Army.

The various federal agencies provided physicians by the Civil Service Commission employ about 2,500 doctors and need about 400 new men for replacements or for new positions each year. For the present fiscal year they lack 250 physicians to meet their requirements.

It is also pointed out in the analysis that the approximately 5,000 physicians graduated from medical schools of the United States each year are about the number needed to supply the hospitals capable of extending the education of the young physician by an internship with the interns that they require. Many smaller hospitals now are finding it difficult, if not impossible, to secure interns.

In addition to the demands made on the medical profession by the various governmental services there also is the necessity for some service related to civilian defense, to the Selective Service, and to expanded war industries.

BACKED BY A RECORD OF OVER 16 YEARS

Koromex Diaphragms provide the most thoroughly tested, thoroughly proven diaphragms offered. Koromex Jelly, likewise proven in clinical use, is a thoroughly buffered lactic acid preparation. Woman's Auxiliary

To the Medical Society of the State of New York

MRS John L. Bauer tells us in our national *Bulletin* that the functions of the State Auxiliary may be listed thus: To help with the entertainment of the wives of doctors at the state medical society meetings, to aid in the program on health education, to take active part in all public health movements, to encourage periodic health examinations, to encourage birth registration work, to aid in securing better medical legislation, to assist families of doctors in need, to promote *Hygeia*.

These are but a few of the many worthwhile reasons for a state auxiliary.

County News

Albany. At the last meeting held at the Nurses' Auditorium of the Albany Hospital fifty-five members and thirty-nine invited guests were present. Dr. John M. Swan spoke on "Choose to Live." Movies illustrated the talk. Dr. Swan is executive secretary of the State Committee of the American Society for the Control of Cancer.

The open meeting was so successful that the November meeting was also opened for invited guests. Dr. Harold Street, of the Winthrop Chemical Company, gave a talk on vitamins.

Fulton. At a recent meeting held at the Eugene Lettaver Memorial Laboratory, Mrs. J. Edward Grant, president, presided. The chairman of committees gave reports. Mrs. Leslie Backus, hospitality chairman, reported on the successful and enjoyable dinner held at Newman's Lake House, Saratoga. Mrs. Grace Taylor Fryc, secretary of the Gloversville Red Cross, gave an interesting and instructive talk on the work of the Red Cross since its forming and asked for full cooperation and help at this critical time. Mrs. Louis Tremante and Mrs. Arthur Wilsey represented the auxiliary at a Nutrition Dinner at the Hotel Johnstown.

Jefferson. On November 13 a dinner was held at the Black River Valley Club. The project that the auxiliary members are working on now is the sale of Christmas Seals for the tuberculosis campaign.

Montgomery. At the October meeting held at St. Mary's Hospital, Mrs. Josephine Secor, district supervising nurse of Amsterdam district of the New York State Department of Health was guest speaker. Mrs. Secor explained the value of the auxiliary's participation in home hygiene and first-aid classes. She also told of the need for all individuals to be prepared to meet an emergency. At the business meeting, plans for the coming year were made. Those present were: Mrs. S. L. Hominghouse, Mrs. Walter Dreyfuss, Mrs. Max Gutman, Mrs. James P. Curran, Mrs. Leonard M. McGugan, Mrs. William H. Seward, Mrs. Edwin B. Kelly, Mrs. Edward A. Bogdan, Mrs. Roman R. Violyn, Mrs. P. J. Fitzgibbons, Mrs. Melvin T. Woodhead, Mrs. Martin F. Geruso, Mrs. John G. Butkus (Hagaman), Mrs. Raymond E. Wytrowski (St. Johnsville), and Mrs. Josephine Secor.

Nassau. On Saturday, December 6, the Medical Society and Auxiliary Dinner-Dance will be held. On Tuesday, December 16, at the Nassau Hospital Auditorium at 8:30 P.M., the auxiliary Christmas party will take place.

Onondaga. The November meeting was held at the Nurses' Recreation Hall of the Syracuse Memorial Hospital. Forty-two members were present. Dr. Eugene Davidoff of the Syracuse Psychopathic Hospital Staff gave an address on "Child Guidance and Mental Hygiene."

Mrs. Walter W. Street, first vice-president, presided at the meeting in the absence of Mrs. Edgar M. Neptune, president. Mrs. Nobel Chambers, chairman of public relations, announced her chairmen of the various charitable endeavors planned for the year. Mrs. Mortimer G. Brown heads the auxiliary group of volunteers at the Syracuse Free Dispensary, Mrs. Brewster Doust, the workers on nutrition, Mrs. P. K. Menzies, the work on the collection of surgical instruments for Bundles for Britain, and Mrs. Oren D. Chapman, the Red Cross work. Mrs. Ned Paul, chairman of *Hygeia* magazine, gave an enthusiastic report, hoping to swell the sale of subscriptions for this year.

Mrs. Winthrop Pennock will be the guest of honor and speaker at a formal dinner for members of the auxiliary to be given at the Hotel Syracuse on Tuesday evening, December 2, at seven o'clock. All members are cordially encouraged to attend. Mrs. John Buettner and Mrs. Francis Irving are general chairmen.

Mrs. Ferdinand Schoeneck is chairman of the hostess committee and is assisted by Mrs. Ellery Allen, Mrs. Wardner Ayer, Mrs. Robert K. Brewer, Mrs. Jerome E. Alderman, Mrs. Joseph I. Alpenn, Mrs. William E. Ayling, Mrs. George Andrews, Mrs. Armand Aquilino, Mrs. Albert Bailey, Mrs. James Brown, of Cleveland, Mrs. Eugene Bogardus, and Mrs. P. F. Britt.

Queens. At the regular meeting on October 28 Mrs. Michael M. Schultz, president, presided. Mrs. Thomas D'Angelo, chairman of Red Cross, reported 572 hours' work turned in, and service pins were awarded to Mrs. Alfred Angnst and Mrs. Walter J. Lynch. The success of the Health Defense program was due to the hard work of Mrs. Lynch and her committee. An all-day program of the Second District New York Medical Society was held October 30, at Garden City. Mrs. William Godfrey was in charge of the luncheon and Mrs. John Finnigan was in charge of the bridge.

Mrs. Michael M. Schultz entertained twenty-five members of the Executive Board at a luncheon at the North Hills Country Club on November 10. The regular meeting followed. Election of officers took place at the meeting on November 25. Mrs. Irving Poneman is chairman of the nominating committee. The proceeds of the dinner-dance held on November 15 were turned over to the medical society.

AFTER FORTY CENTURIES...

"They purge themselves every month, three days in succession," says Herodotus, seeking to preserve health by emetics and clysters. — *Garrison History of Medicine*, pg. 41.

AFTER 40 centuries—or more—of purges, cathartics, 'roughage' and enemas, a rational regimen for the spastic bowel has been evolved

It is this—a smooth, bland, chemically inert muciloid is used to encourage normal peristalsis and facilitate elimination without irritation of any sort.

To do exactly this, Searle Laboratories have produced

Metamucil-2

—a highly purified extract of *Plantago Ovata*-Forsk., which mixes easily with water or fruit juices to produce the necessary mucilloid gel, "Smoothage."

Specify Metamucil-2 "Green Label"

Metamucil-2, the new 'Smoothage' product, is distinguished by a green label. The therapeutic principle is the same as that of Metamucil but the base used in Metamucil-2 affords a more palatable, easy-to-mix product. To insure your patient's obtaining the new product, specify 'Metamucil-2—Green Label'.

Supplied in 1 lb., 8-oz. and 4-oz. containers

SYPHILIS RATE OF 45.2 CASES

"per thousand persons examined was found through physical examinations and routine serologic blood tests of the first million selectees and volunteers called for classification under the Selective Service Act of 1940," R. A. Vonderlehr, M.D., and Lida J. Usilton, M.A., Washington D. C., report in the *Journal of the American Medical Association* for October 18.

"The greatest prevalence of syphilis among the selectees and volunteers was reported by Florida and South Carolina, with rates of 170.1 and 156 cases per thousand, respectively," they say. "The lowest rate, of 5.8 per thousand, was reported by New Hampshire. Seven Southern states and the District of Columbia reported rates in excess of 100 cases per thousand. The rate for Negroes is consistently higher than that for white men in all the states. There are indications that high rates among the whites are coincidental with high rates among the Negroes. For the country as a whole, the prevalence of syphilis among negro selectees and volunteers is thirteen times that for the white. In twenty states and the District of Columbia the negro rate is in excess of ten times that of the white."

THE NOSE KNOWS

How to answer a phone call, yet avoid having to make a needless visit to a patient, is disclosed by an unnamed physician-correspondent of the *British Lancet*. His letter says, in part:

"To answer in your own voice is to be left defenseless in case of an unurgent call, and few people can disguise their voices effectively. Now—grasp the telephone in your right hand and your nose in your left."

"Is the doctor in?"

"I don't think he is, but I'll go and see. Who is it speaking, please?" says a strange nasal voice that you wouldn't recognize yourself.

"Lay down the phone and tap with your foot on the floor, *diminuendo*. That is Nosey going away to find the doctor. You may breathe naturally now and think the matter out. After a suitable interval you tap on the floor with your foot again, this time *crescendo*, pick up the phone, and (a) gripping the nose as before, 'I'm sorry, the doctor isn't in at present. Can I take a message, Mum?' or (b) in your own voice 'Hello, Jones, about that match.'"

—*Medical Economics*

HEALTH EDUCATION CONSULTANTS TO BE ASSIGNED TO KEY DEFENSE AREAS

A vital part of this nation's "all-out" defense effort is the safeguarding of its health. The rapid growth in industrial and governmental production has caused unusual concentrations of population and increasing health problems. To assist state, county and local health officials in coping with these problems, the U. S. Public Health Service is planning to appoint health education consultants to various defense areas. The positions, paying \$2,600 to \$3,800 a year, will be filled through the open competitive examination process and the Federal Civil Service Commission has just issued the examination announcement. A written test will not be given, but applicants will be rated on their qualifications as shown in their applications and corroborative evidence.

Appointees will work with local health officers and their staffs, advising them as to methods, and procedures of health education such as individual instruction through interview, group

instruction through discussions, talks, lectures, and other educational techniques. To qualify for the positions, applicants must have completed a four-year college course, including or supplemented by special study—or for the assistant grade, experience—in public health. In addition, they must have had experience in public health education work coordinating the activities of all organized health groups in a community for the purpose of promoting a public health program. This experience must have been in a federal, state, or official local public health department or in a voluntary agency such as the Red Cross, Tuberculosis Association, or the like.

Applications must be filed with the Civil Service Commission in Washington, D. C., not later than December 11, 1941. The examination announcement giving detailed requirements can be consulted or obtained at any first- or second-class post office or at the central office.

TRAVEL MEDICINE

"We are hunters pursuing the Summer on snowshoes
 and skates, all Winter long There is really but one sea-
 son in our hearts," wrote Thoreau

Winter vacationing has changed some since "dad
 was a boy" and considerably since Thoreau wrote the
 idea of no definite season for travel, so pointedly

Those were the days when travel horizons were limited
 and vacations for the average person were one-day holi-
 days. Weekends were not popular as an opportunity to
 spend two days and three nights hundreds of miles away
 from the home fires. A trip to Florida was unheard of
 off Park Avenue or whatever street it was that the four-
 hundred wintered on in those days

Common travel opportunities, increasing from year to
 year, have done much to raise the standards of living
 When you find more than half of a nation travel-minded,
 there is bound to be improvements in hygiene at home

No one can stay at modern hotels and mingle with others
 from every point of the compass without wanting to im-
 prove daily living and conditions at home

Travel methods, too, have changed. The open high-
 way has no discrimination It supports the most eco-
 nomical conveyance as well as the most luxurious motor
 car The railway coach, today, is superior to the parlor
 car of even a decade past And, the skyways even carry
 the ski enthusiast to trails that would otherwise be far
 beyond reach

The only sad note in the vast improvements is the
 fast disappearing explorations by foot Even the tramp
 can thumb a way to cover ground more quickly and more
 lazily

But, where we used to wear out more footwear, we
 now use up more trousers

And, everybody seems happy just the same

vertisement—or the advertisement has failed its purpose—to interest you.

Now you may ask, "What of it?"

Nothing—except that unless your "I Q" (in this case, "Inquisitive Quotient") is high enough to urge you to delve into even advertisements, you are not giving yourself the benefit of every angle of modern medicine

The Physician—History's Confederate

The father of the "Father of Our Country," Captain Augustine Washington, procured the services of a Dr. Green. In addition to the requirements of his medical abilities, it was the duty of Dr. Green to prescribe to the spiritual needs of the early settlers in that wilderness which has since become the City of Washington, Arlington, Alexandria, Mount Vernon, and vicinity

Dr. Green also gave spiritual as well as medical advice to the child George Washington while the Washington family were living in their Little Hunting Creek home. He continued these duties in the service of General and Mrs. George Washington and other members of the Washington family until his death in 1765

So the physician-preacher played just as important a role in the foundation of our country as did the patriots who rebelled for liberty ten years after his death. Dr. Green never lived to see his famous patient become the first President of a new nation and a leader of the greatest freedom human beings have ever enjoyed on this earth, but he had a share in our destinies for which we should acknowledge some indebtedness

For who knows how much of Washington's character, wisdom, and health this venerable old gentleman's medical and spiritual treatments were responsible for? Who knows how much a certain event at Yorktown depended on the patient, conscientious care of a simple, country doctor?

COT-TAR PIX-LITHANTHRACIS 5%

- Therapeutically active in eczema — particularly suitable in children's eczema
- Forms a flexible non-peeling coat of tar
- Can be removed with water or cleansing creams
- Avoids staining of linen
- Causes no untoward irritation

ESTABLISHED 1889

THEODORE W. NEUMANN, M.D., Phys. in-Chg
CENTRAL VALLEY, Orange County, N. Y.

WHAT ABOUT WHAT?

In one of his books, Mr. Rudyard Kipling wrote so effectively—

"I have six honest serving men

They taught me all I know

Their names are *What* and *Where*, and *When*,

And *How*, and *Why*, and *Who* "

The youngest and perhaps busiest of these six brothers, is *Why*. He is the choicest friend of young children, answering their very first question and the millions of juvenile questions asked since the beginning of time.

The second brother, *Who*, is also a busy chap, but often a bit of a snob. He is a pet of the gossips, yet wise, worldly wise and a great social consultant. The next in the family are the twins, *When* and *Where*. These friendly fellows are the directors who guide us out of problems.

But *How* is even a more important adviser. He combines the knowledge of all the failures and successes of mankind. His true name is Experience. *How* is the faithful friend and guide to the creative talents of men, and the keeper of the keys to achievement. The older we get, the more we consult him and the more we depend on his guidance.

Why and *Who*, and *When* and *Where*, and *How*, are inseparable and indispensable in the lives of every being. But what about *What*, the sixth of these serving men of Kipling's?

What is the check-rein to our emotions—the chap who can save us from error. He is really the analyst, skilled in analyzing the action we should take or perhaps should not take. He is the shadow of his brothers, for we can seldom ask *Why*, *Who*, *Where*, *When* or *How*, without a complementary *What*.

Read a scientific article and you will question, perhaps only subconsciously—*Who* wrote it? (*What* can he tell me?) *Why* was it written? (*What* value has it?) *When* and *where* were the facts obtained? (*What* authority makes them valid?) *How* can the material serve me? (*What* shall I do with it?) And perhaps in conclusion—*What* do other doctors think of it?

The same gamut of questions will run their course if an advertisement arrests your attention. Unconsciously, you will ask the *Why* and the *What*, the *Where* and the *When*, and the *How* and the *Who*. If you do not, then you will fail to derive any benefit from reading the ad.

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1941 by the Medical Society of the State of New York

VOLUME 41

DECEMBER 15, 1941

NUMBER 24

Editorial

Christmas, 1941

Mr Winston Churchill in one of his early speeches referred to the achievements of Britain's air force in these words "Never was so much owed by so many to so few"

It is time that we consider a little when those words could have been spoken with equal applicability in former times

Certainly, as we approach the significant festival of the Nativity, the whole surviving Christian world, threatened with extinction of its religious beliefs, has reason to reflect upon its debt to the Jew of Nazareth and His twelve followers, one of them a physician

"Never was so much owed by so many to so few"

Are we prepared to begin repayment? The answer, this Christmas season, 1941, lies in the hearts and in the souls of all men of good will of all nations every-

where Clear-headed men are arising in wrath and indignation against the brokers of treason, the knavery of false leaders, against the proponents of slavery, against those who propose to provoke a war that is half peace in the hope of a peace that would be all war

"Never was so much owed by so many to so few"

Abraham Lincoln said in 1863, "and by virtue of the power and for the purpose aforesaid, I do order and declare that all persons held as slaves are, and henceforward shall be, free,

"that this nation, under God, shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth"

"Never was so much owed by so many to so few"

Alcoholism a Challenge

Is alcoholism an unsolvable problem? How long will it continue with sardonic hideousness, with all its consequences of "shattered prospects, blighted homes, crumbled faith of children, and the individual's own misery" to defy an all-out attack by the combined forces of modern science, modern medicine, modern sociology, and modern mental hygiene?

"Alcoholism," says Dr Eugene N Boudreau in a provocative article, "The Medical and Social Challenge of Alco-

holism," on page 2407 of this issue, "is a major health problem It is a cancerous condition in our social fabric I would have you disclaim and eliminate any ethical or moral qualifications and accept the fact that it is a malady—a sickness" In this manner does Dr Boudreau throw the problem squarely into the lap of medicine to be studied like any other disease, syphilis or tuberculosis, for example, without prejudice or bias

his sins, his disgrace, his shame, his faithlessness to his obligations "In the name of family, associates, friends" and so on. This is done in the hope of "making a man of him," but it accomplishes little except to increase the load of guilt the sufferer carries, which is already part of

his unfortunate drive for release from the pain of his environment

Here, indeed, is a challenge, as Dr Boudreau points out To meet it calls for scientific, orderly changes in medical and social attitudes and the greatest possible use of every educational facility

The Good Doctor

Once upon a time there was a good¹ doctor ² He lived in a house³ with his wife,⁴ two children,⁵ and a F H A mortgage ⁶ He had an automobile ⁷

In the morning he took the children to school⁸ on his way to the clinic,⁹ where he spent the forenoon caring for the poor¹⁰ sick people without recompense ¹¹

One day¹² in the clinic⁹ in the course of his work¹³ he came across a lunatic,¹⁴ who said to him

"You think I'm crazy,¹⁵ don't you?"

"Yes," said the doctor, "I am afraid I do "

"Well, that's all right with me, would you care to know what I think of you?"

"Not particularly," said the doctor

"It's always that way," said the poor lunatic, apologetically, "and yet kings used to listen to us, you know, in the old days "

"I know," replied the doctor who was in a hurry to get through his work, "but those days are gone and so are the kings Besides," he added as an after thought, "they didn't pay any attention even then Next case "

So they took the poor zany¹⁶ to a state hospital where he got the best of everything for the rest of his life

The good doctor got in his automobile and drove home to his office As he put on his white coat and washed his hands before seeing the accumulated Customers¹⁷ he shook his head and murmured, sympathetically, "The poor nut "

Hospitals, Attention¹

As we were going to press on December 9, the following telegram was received

Office of Civilian Defense requests you urge all hospitals to establish immediately emergency medical field units in accordance with plans outlined in Medical Division *Bulletins* No 1 and 2 and drill weekly Where necessary, reserve field units should also be organized with medical nursing and trained volunteer personnel derived from the community Urge immediate action

GEORGE BAEHR, M D
Chief Medical Officer

Such a challenge cannot be ignored or side-stepped. The last World War provoked a legislative onslaught, noble in motive, ill considered, ill conducted, disastrous in outcome, on the problem of the alcoholic. Now another period of world chaos finds us little more advanced in scientific knowledge of alcoholism, except perhaps that we know the legislative approach does not answer Omar's question.

"I wonder often what the Vintners buy
One half so precious as the stuff they sell "

Has medicine any better approach? We think so. The Research Council on Problems of Alcohol, an associated society of the American Association for the Advancement of Science, has for some time had this problem under close scientific scrutiny. Its publication, the *Quarterly Journal on Problems of Alcohol*, is now in the hands of many practitioners of medicine, as well as in those of the public, spreading accurate, scientific information as to the known facts concerning alcoholism as a disease. The Council's address is 111 Pondfield Road West, Bronxville, New York.

Dr Boudreau at the conclusion of his article says "Our profession should accept the challenge, seek by research for the complete medical solution and, above all, afford leadership in a social movement against excessive drinking. More drinking inevitably is followed by more addictions and other alcoholic disorders." At its annual meeting on November 25, 1941, the Research Council on Problems of Alcohol held group conferences under these heads:

- The problem of alcoholism and excessive drinking in industry
- Research on the relation of alcohol to industrial efficiency—for personnel and medical directors
- Problems of the family doctor, clergyman, and layman in dealing with alcoholism
- Research on alcoholism and the alcoholic psychoses
- Alcoholism as a public health problem

Methods of treatment for alcoholism

The problem of the acute alcoholic—in city hospitals, correctional institutions, courts, and police departments

Alcoholism as a problem in social work

The problem of alcoholism as related to the legal, trade, and social controls of the sale of alcoholic beverages

This seems to be a direct answer to Dr Boudreau's challenge to the profession. It is far from a solution, but there is no ending that does not have a beginning. The problem cuts squarely across the field of mental hygiene, leaving an unlovely trail of human wreckage to encumber the machinery of industrial production and a continuing problem to engage the attention of the committees on public health of the various county and state medical societies.

The laymen have not been inactive respecting this problem. *The Mind That Found Itself* by Clifford Beers paved the way for a change in professional and popular views about mental cases, which change was marked by the widespread substitution of the term "mental disease" for the term "insanity"—a positive thought replacing a negative one. The story of a rapidly growing lay movement is told in the volume *Alcoholics Anonymous*, the textbook of groups known by this name. The book has helped many men and women to recover from alcoholism by a spiritual approach—empirical, but useful. Today, there are ninety of these groups that have sprung up throughout the country as a result of the distribution of this book, which may be had from the Works Publishing Company, Box 658, Church Street Annex, New York City. Representatives of *Alcoholics Anonymous* are admitted to call on patients in a number of leading hospitals in several cities, one hospital in a suburban town sends a bus load of patients to the weekly meetings of the New York City group.

Most people, and some doctors, attempt to cure the alcoholic patient by "reading the riot act" to him, picturing

THE DIET OF YOUNG INFANTS

CHARLES HENDEE SMITH, M D , New York City

THIS contribution deals with the methods of feeding and the food requirements of the infant in his early months, especially in the neonatal period. The artificial feeding of infants throughout the first year has been discussed elsewhere.^{1,2}

The first question that confronts the physician in charge of a newborn infant is "breast or bottle?" There should be no question as to which is the best food for infants. All authoritative teachers and texts agree that breast feeding is the method of choice unless the mother's health, physical or mental, is below normal, or unless there has been more than one failure in nursing previous babies. It is not necessary to enumerate all the diseases that contraindicate nursing, since any condition that impairs the health of the mother is enough to do so. Breast feeding is good for the mothers, too. Nursing stimulates uterine contractions, promotes involution, and gives the mother a psychologic satisfaction and comfort surpassed by nothing else in life.*

It has been too well known to need corroboration that breast-fed babies not only have a better chance of survival than bottle babies but also have less acute respiratory illness, have fewer digestive upsets, and gain more surely in the early months. Statistical proof of this has been furnished by Faber and Sutton,³ Grulee,⁴ et al., Griffiths,⁵ and others.^{6,7,8}

But what is the common practice today in this matter? It is an unfortunate fact that instead of being urged and encouraged to nurse her infant the slightest hint from the mother that she wants the baby to be bottle-fed is

taken as ground for weaning. Every possible obstacle is placed in the way of the mother who wishes to nurse her baby by many physicians and nurses. The result is that few babies born into the private-patient class are now breast-fed. It is easy to prove this by visiting the nursery of any private obstetric hospital and asking the nurse in charge the general attitude toward breastfeeding (footnote,* p 2396).

The decline of breast feeding has been depicted by many writers.^{9,10} This is attributed by some to the improvement in artificial food methods which makes it much less dangerous to wean a baby than in former times.¹¹ Others blame indifference and mismanagement. On the other hand, several studies have shown that in some parts of the world and in certain classes of society there is no real falling off in the percentage of breast-fed babies.^{12,13}

Breast feeding is not a lost art, but its management is a real art. The results of a number of studies show that the great majority of mothers (90 to 95 per cent) can nurse their babies when properly encouraged and supervised. The pioneer work of Sedgwick in this field is a perpetual example.^{12,13,14} Breast feeding is the routine method in the nurseries at Bellevue Hospital. No baby is given a bottle until nursing has been given a fair trial. Sugar solution is the only prelacteal feeding and babies take very little of it—only a few ounces a day in most cases. Only 10 per cent of the babies receive any artificial food during the ten days in the hospital. Artificial feeding is used only when the mother is tubercu-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

From the Department of Pediatrics, New York University and the Children's Medical and Obstetrical Services, Bellevue Hospital.

*A recent article by a mother (Brown, Elizabeth, *Ladies Home Journal* 23 (Jan.) 1941) tells the story better than any words of mine.

'American women have been charged recently in fairly harsh terms with refusing to nurse their babies. And the implication is that they are vain selfish lasses or to say the least uninformed.

The last of these reasons—and only the last I think—is true. Women are uninformed about nursing. It isn't by any means so simple as the books say. It's a difficult, perplexing, sometimes dismaying experience. There is nothing natural about it, if you think of natural processes as occurring effortlessly. But for the mother who surmounts these obstacles nursing her baby is a rich, glowing experience, bringing with it an incomparable sense of peace and completion.

Medical men, psychologists, and almost every mother who has nursed her baby agree on the wisdom of nursing.

The baby's greatly increased chances of staying well during the first year and of developing into a happy confident child are matched by the mother's own deep sense of fulfillment. But too many mothers are uninformed on the first point and so never discover the second. I am convinced that if women were better prepared for the problems of nursing and realized the immense satisfactions to be gained from it a much larger number would insist on breast feeding their babies.

The writer then describes how the first baby was weaned before she left the hospital because she wasn't getting enough milk. She says: 'The whole experience left me feeling dismayed and somehow inadequate. She was determined to nurse the second baby and did so successfully in spite of attempts to discourage her.

The outcome was an unqualified success. The baby not only grew well but enjoyed his feedings enormously. With this intimate contact I came to know him more quickly as an individual. The price of being at home at fixed times every day and of leading a more regular and somewhat less active life than usual was indeed no price at all but a rich and profitable interlude physically, emotionally and intellectually.

Correspondence

DR ARCHIBALD McNEIL AND THE GONORRHEAL COMPLEMENT FIXATION TEST

To the Editor

In the passing of Dr Archibald McNeil on October 13, America has lost a distinguished serologist. It may be fitting to pause and pay tribute to a colleague who so brilliantly and modestly contributed to our knowledge of one of the diseases which still remains a public health problem in our midst.

Coming from New Haven where he had founded the first bacteriologic laboratory of the Department of Health, he became associated with the New York City Department of Health and worked there for many years.

In 1912 Dr McNeil, in collaboration with Hans G Schwarz, drew attention to the value of a blood test, the complement fixation test, for the diagnosis of gonorrhea. From that time until his death he remained an exponent of the value of this test. Dr Archibald McNeil, of America, and Orpwood Price, of London, have proclaimed its value for twenty years or more.

Dr McNeil always coupled his laboratory research with careful bedside observations on the part of the clinician in charge and checked his findings with other serologists with whom he had worked intimately. Thus, his work on the gonococcus was associated with William H Park, Anna W Williams, M A Wilson, Annis Thomson, Agnes Hamann of the Research Laboratory, Department of Health, Hirschland in Pennsylvania, and other serologists. For many years his work was carried on clinically in the female gonorrheal wards of the Kingston Avenue Hospital on the service of Dr E D Barringer.

A number of private grants of money were made by public spirited citizens who were interested in the effort of standardizing this blood test for gonorrhea. Thus, Mrs Charles Day, of Philadelphia, Honorable Lucius N Latta, of New York City, and others made this research possible. The results of this work were widely reported before the American Medical Association and other scientific societies and published.

With the onset of the Antivenereal Disease Drive and the appropriation of large federal funds to finance research on the gonococcus, these private grants stopped in favor of this governmental help. It is a matter of immeasurable regret that funds appropriated by the generous well-wishing taxpayers for research in venereal disease should not have been protected from political spoil.

In the allocation of these federal funds Dr McNeil was unable to secure any grants to finish up the work he had in hand. However, it is an ironic fact that in spite of the lack of this appropriate financial help he was able to continue singlehanded in his own private laboratory. His technic today, with the modification of Thomson and Hamann, is the most widely accepted of any here in America.

It has been said by many clinicians in discussing the complement fixation test for gonorrhea that it is uncertain "unless done by Dr McNeil himself." Dr McNeil realized the

importance of this criticism but believed that with further intensive study and standardization of details necessary in its performance the test could easily be made available to the skilled laboratory worker. He always stated that the test called for a skillful and well-trained technician but that there was nothing inherent in it that need be considered a variable. I quote his own words: "With the antigen as now prepared it should be possible for any technician who can properly standardize complement and perform satisfactory Wassermann tests to obtain accurate and reliable results that will satisfy clinicians with the complement fixation test for gonorrhea infection."

His last public pronouncement was at the Post-Graduate Fortnight of The New York Academy of Medicine in October, 1940.

At that time, in a joint exhibit with Barringer and the Staff of the Gonorrheal Service of the Kingston Avenue Hospital, a statement in regard to the suggested standardization of tests for the diagnosis and tests of proof of cure of gonorrhea in the female was made.

What will be the future of the complement fixation test? Will it hold a recognized standard place in the departments of health that the Wassermann test does for syphilis? Only time and further clinical experience can answer that.

Gonorrhea is at the crossroads today with regard to its future history. If the sulfonamides with their apparent brilliant cure are really what they seem and if one can be sure that a negative spread and culture of available discharges prove this cure, then there would seem to be little need for further tests and gonorrhea may quickly be rated an unimportant infection.

To those who have studied gonorrhea over a period of years and have realized its many manifestations as a general systemic disease and, especially in the female, have noted its carrier quality—in that latent foci may harbor viable gonococci—it does not seem likely that the careful conscientious physician will be willing to discharge his patient on only a negative spread and culture of available local discharges. An intimate knowledge of how sulfonamides affect the morphology of the gonococcus and of the difficulty of detecting it accurately after their use would add to the hesitancy on the part of the clinician in being willing to forego a reliable serologic test.

Also there are other needs for a gonococcal complement fixation test which should not be overlooked, such as its simultaneous use with the Wassermann test in premarital blood examinations and in the examination of employees, especially nurses and attendants who care for little children.

If and when all these considerations fall into their proper perspective in the problem of gonorrhea as a whole and when the need for a serologic test is proved, it is to be hoped that the McNeil-Thomson-Hamann technic will receive the full recognition it so richly deserves.

BREAST FEEDING - NEW BORN

BOTH BREASTS 8 MIN EACH EVERY 4 HRS 6 FEEDINGS

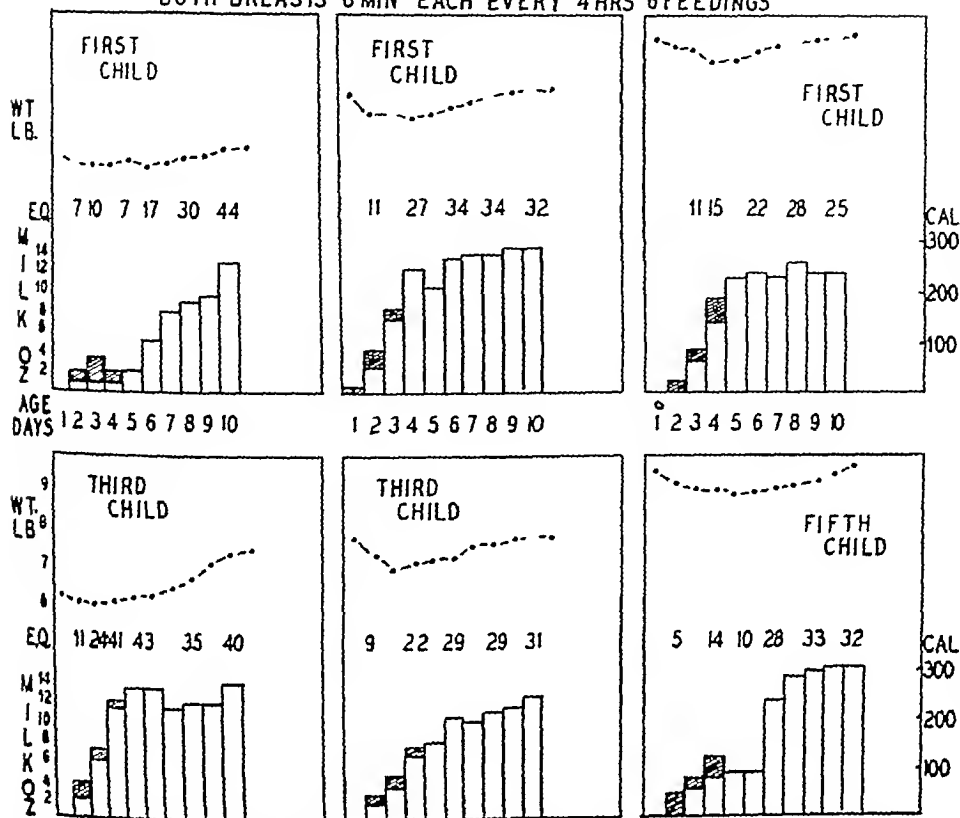

FIG 1 Shows amount of milk obtained by six babies in first ten days of life. Shaded blocks represent calories from sugar solution. Note the low energy quotient throughout and satisfactory weight curve. Numbers indicating weight were omitted from upper blocks by an error. They should be as in the lower blocks. The first baby weighed $6\frac{1}{4}$ lb, the second $7\frac{1}{4}$ lb, the third, $9\frac{1}{4}$ lb at birth.

the Bellevue class and from private practice make it fair to conclude that 90 per cent of the mothers can nurse their babies for two months or more if they are properly encouraged and supervised.

Most of the trouble arising during breast feeding is due to neglect or ignorance of the simple principles upon which its success depends. It is worth while to review the fundamental facts that the physician should bear in mind and about which it is his duty to instruct the mother. This story is an old one but, like many, it needs to be repeated from time to time lest it be forgotten.

Early weaning is ordered by some obstetricians because the milk is slow in coming or the supply seems to them to be inadequate. It is well known that little or no milk is obtained in the first days of life, that the milk only "comes in" after several days—usually by the

sixth day—and that it may take two weeks or more to establish a good supply.

The amount of breast milk obtained by hospital ward babies is illustrated in Fig 1. These are 6 typical cases selected at random from a large number of patients weighed before and after each feeding and representing the behavior of the breast-fed babies born in Bellevue. The birth weight is reached or approximated by the tenth day in most instances. It is obvious that all of them gained as soon as they got about 30 calories per pound about the end of the first week. Few of our babies obtain more than 40 per pound by the tenth day. By the end of the second week, however, infants need 45 calories per pound.

Even though the milk supply is scanty at first, it is a common experience to have it increase rapidly as soon as the mother gets home from the hospital. On the other hand, if she

TABLE 1—BREAST FEEDING—DURATION IN PRIVATE PATIENTS

First Seen	Not Nursed	1-21 Days	3-8 Weeks	2-3 Months	Over 3 Months	Total
Before weaning	2	5	21	42	157	227
At weaning		1	7	2	18	28
After weaning	114	61	56	30	30	300
						555

Note the greater number of breast-fed babies when seen before weaning. These are not selected cases but were taken in alphabetical order from the files of private patients.

lous, acutely ill, psychotic, or otherwise unfit to nurse her baby or when a fair trial shows that she cannot produce milk. When the babies discharged from the Obstetrical Service come to the Outpatient Department of the Children's Medical Service, 85 per cent of them are still breast-fed, although several weeks may elapse between the hospital discharge and the first visit to the clinic.

At Baby Health Stations on the east side of New York City the babies come from several hospitals. A study is under way to determine the character of feeding ordered. On coming to the stations 70 per cent of the babies born in Bellevue are breast-fed, but from one other nearby hospital only 10 per cent are still nursing. From other hospitals 20 to 40 per cent are breast-fed, but none of them approaches the rate of breast feeding of the Bellevue babies.

Table I shows a study of the records of 555 infants, taken in alphabetical order from my files, and should represent a fair cross section of private practice. They are grouped according to the time at which they first came under my care, before, at, or after weaning. Some of the nursed babies obtained all their food from the breast until near the time of weaning, others had one or more bottles for part of the period. But no baby was kept on food from the breast unless he obtained more than half his requirements and was gaining well. These babies divide themselves into five groups by the length of time they were breast-fed.

The first group contains the babies never nursed. Only two mothers seen on the first day absolutely refused to try breast feeding—

one for economic reasons, the other from pure stubbornness. On the other hand, 114 babies whom I saw after weaning had never been put on breast feeding. The reasons were adequate in some instances, but in others they certainly were not.

The second group was nursed from a few days to two to three weeks. This group obviously consists of babies nursed during the time the mother was in bed or just getting up. Only 5 of these were babies under my observation, 1 was seen at the time of weaning, and 61 had been weaned before I saw them. Some of them were weaned because the milk was obviously inadequate, but others who had been weaned before I saw them had had as much milk as could be expected at that period. By the figures it appears that over twelve times as many mothers were discouraged under the obstetricians, as compared with the group encouraged to persist in nursing.

In the third group the babies were nursed three to eight weeks—a longer trial and one that gave the baby time to be educated to artificial food. This must be considered as partially successful nursing. Sixty-three had been weaned before they came under observation as compared to 21 in the group seen before weaning.

The group nursed two to three months shows a reversal of the figures, 42 were under my care, while 32 had been weaned before they were seen. In most cases these babies were successfully nursed until the mother became more active and more tired. This length of nursing is really well worth while.

The babies nursed over three months were the most successfully breast-fed. Of these 157 were under my care against 57 seen at or after weaning.

If one counts all babies breast-fed over two months as successfully nursed, it is noteworthy that 87 per cent of the babies seen before weaning fall into this class. On the other hand, only 29 per cent of those seen at or after weaning were nursed as long as two months. It may be suggested that the babies who were weaned early were more apt to be turned over to the pediatrician than those breast-fed. Careful studies of the histories show that this factor was not important. These facts from

* A few examples are typical. A young married physician was delivered in a hospital recently. She wanted to nurse her baby but was ridiculed by the nursing staff who told her that breast feeding was out of date and that no one would nurse babies in a few years and that she was the only patient in the hospital who was nursing her infant. She insisted, however, and nursed the baby successfully. In a private hospital at a recent visit not 1 baby out of 30 was breast-fed, and in another, only 1 of 35. In one of the best private hospitals in New York City, 2 patients who wanted to nurse their infants reported that they were talked out of it by the nursing staff. A prominent obstetrician told a patient of mine that it is easy enough to feed a baby from the bottle, and there is no use bothering with nursing any more. These examples illustrate the general attitude toward breast feeding and could be multiplied indefinitely.

stetric hospitals the whole management of the infant is left to the nurse by the obstetrician who does not care to bother about the "by-product of the mother's labor." More and more, then, in recent years the baby is turned over to the pediatrician already weaned and, too often, on a feeding that has started an upset. But let the pediatrician beware! No word of criticism may be uttered as to the handling that has caused the trouble. Let him get out of it as best he may. It often exhausts all his resources, scientific and strategic.

The infant lucky enough to be breast-fed requires observation and management as careful as that given to his brother on the bottle. There is no automatic regulator on the milk supply. In the early days little milk is secreted, then the breasts begin to yield abundantly and may overdo the matter, so that an infant of 3 or 4 weeks may obtain almost as much as one of 6 or 7 months. A small baby may find as abundant a supply as a large one. The physician who appreciates this fact will avoid the effects of overfeeding by carefully regulating the time at the breast. He must be equally alert to detect a failing supply. Fig 2 shows the amount of milk obtained by a baby each day in the nursing period. Note the rapid increase of milk up to the point where 60 calories per pound were obtained. It would have been easy to overfeed this baby. It was necessary to cut the number of nursings from five down to four a day for several weeks, then five were given again as the supply began to fail. Note that the baby gained on rather less than 45 calories per pound for most of the nursing period. Heubner¹⁴ published curves showing similar facts nearly forty years ago.

It is not difficult to weigh the baby before and after feeding for a few days and to determine the calories he gets per pound per day. When he is getting too much regularly, the amount can be reduced by increasing the interval, omitting one feeding, shortening the time at breast, using one breast instead of both, or giving water before nursing to take the edge off the baby's appetite. Less frequent and less prolonged nursing not only gives the infant a smaller individual meal but automatically cuts down the supply by diminishing the stimulation of the breasts. It is then necessary to watch the supply or it may be cut too much, but it can be increased by longer nursings and by using both breasts at each feeding again. I have never found a mother willing or able to increase the milk by manual stripping.

FIG 3 Shows the daily and hourly variation of breast feedings in 2 babies of the same mother. Each block represents three consecutive days. Note the great difference in the amount obtained at different feedings. Some were much larger than is usually expected. It was impossible to estimate the size of the feeding from the baby's behavior.

The rate of secretion of breast milk at a feeding must be remembered, for only by a knowledge of this rate can we regulate the time at a feeding. The baby gets about 75 per cent of the milk obtained at a nursing in the first two to four minutes.¹⁶ A nursing of six or eight minutes is usually adequate, though the infant may be allowed to suck for ten minutes to strip the breast and thus stimulate the milk secretion if necessary. Further nursing merely macerates the nipple and predisposes it to cracking, makes the mother nervous, and fills the infant full of swallowed air. When the milk supply is overabundant, the time may be cut to three to five minutes or even less, especially in the morning. One of my patients got all he needed in forty seconds!

The amount of milk obtained at a nursing varies greatly. As a rule, in the morning more milk is secreted, while the supply drops off toward night. This daily variation seems to do no harm, for a baby will often go as long after a small feeding as after a large one. The total daily amount is the important thing. Surprising extremes are often seen. Fig 3 shows the daily variation in 2 breast-fed infants of the same mother. It seemed to make little difference to the babies whether they got 4 or 10 ounces at a meal. On one morning one of them, at the age of 3 months and weighing 12 pounds, took 12 ounces without any sign of discomfort.

BREAST FEEDING

FIG 2 Weight curve, dotted line, average breast-fed baby's weight, broken line. Vertical solid lines show amount of breast milk obtained each day during nursing period. Broken lines show calories in artificial food. Curve at bottom of chart shows fluctuation of calories per pound day by day. Note low calories early, rapid increase to 60 per pound at three weeks, then less when only four feedings were given. Note good gain on low calories most of time.

does too much and gets too tired in the third or fourth week, the milk supply may fail. It is impossible to determine during the hospital stay what will happen in the weeks during which the mother is getting back to normal life. Therefore, no obstetrician is justified in predicting whether a normal healthy woman can nurse her baby until she has been given a fair trial.* Naturally he is (or should be) the best judge of her health and strength, and it is quite within his province to decide whether

she should be allowed to try breast feeding. Too often he discourages her, or lends the weight of his influence against nursing, when a little explanation of its advantages would convince a mother who is not aware of all the facts. Surely this is a problem in the decision of which the pediatrician is entitled to share.

The nurse who interferes in the matter is stepping outside her province in a most unprofessional way. Unfortunately, in many ob-

*A recent example. A mother had successfully nursed her first child for three months. He gained well and was weaned only because the mother was anemic and nervous after a severe first labor. Her second baby was ordered off the breast by the obstetrician on the eleventh day because she was only giving half the needed milk.

The chart showed that this baby had obtained 7.9 8 1/2 10 and 13 ounces of milk on the sixth to tenth days as

much as the average baby gets at this time! The mother was in fine condition after this easy labor and was willing to try nursing further especially since she had to travel to the West in a few weeks. It is probable that the breast supply would have been better and better in the next few days. To wean a baby who obtained 13 ounces of milk on the tenth day showed a profound ignorance of the whole psychology of breast feeding. (Incidentally the bottle feeding ordered provided 55 calories per pound, and the baby gained 11 ounces from the eleventh to the fifteenth day—not a desirable rate.)

BREAST FEEDING

FIG 4. Each horizontal line indicates the duration of breast feeding in an individual case. When on mixed feeding (broken lines) only one or occasionally two bottles were given. All babies obtained more than half their requirements from the breast. The average duration of nursing is about four and one-half months.

not make milk on a reasonably balanced diet, she will not do so on overeating. An extra glass of milk with one meal is desirable, but the mother who takes a quart or more above her normal diet either gets too fat or has indigestion. Many mothers need an iron tonic for the anemia following labor and the not inconsiderable drain of iron in the breast milk.

Breast feeding may be considered successful if it can be continued long enough to educate the baby to artificial feeding when that becomes inevitable. The length of the period on the breast is less essential than the result. It is not necessary for it to continue for many months but, if the baby can be carried through the neonatal period and for several weeks thereafter, he is better fit to cope with artificial food. Even if weaning is necessary in

the second or third month, breast feeding is worth while, provided the baby gets enough milk to take him past the dangers of early weaning.

Weaning should be gradual rather than sudden, substituting one bottle at a time for a breast feeding. The baby who has had water from a bottle from birth will take artificial food easily. It may be extremely difficult to make him take the bottle if he has never encountered one before. For this reason all babies ought to have water or sugar solution from the bottle while they are breast-fed. One bottle of formula in the middle of the night to give the mother more sleep may be given in the early weeks if there is a nurse on duty. An occasional bottle during the day gives the mother a little freedom and a sense

Many mothers and nurses are uncertain as to whether one or both breasts should be given at a nursing. The answer is simple. If the supply is abundant one side is enough, if not, both may be given. It is best to start on a different side at each feeding, to let the baby nurse longer on the first breast, and to fill him up with "dessert" from the second breast. Yet, in one New York hospital the routine allows only one side for twenty minutes and orders a bottle if that is not enough!

The interval between feeding depends on the size of the baby. A small or premature infant may be fed every two hours, one of 5 to 7 pounds may need three-hour feedings, but babies of 8 pounds or more will usually go for four hours. A good rule is to put a baby on four-hour feedings as soon as he is able to take enough at a feeding to last four hours. But to make a small infant go so long is difficult and to insist that all infants of all sizes must go four hours between feedings is unkind, unwise, and impracticable. Larger babies after the first few months may go five hours without undue hunger.

The number and hours of feedings depends on the interval. Small babies on three-hour intervals need seven feedings, larger ones on four hours only require five or six. Some thrive on four feedings at five-hour intervals. Small premature infants must be fed as often as every two hours. As soon as the baby will go all night he should be allowed to do so, but it is unwise to try to make him skip the 2-00-A M feeding if he awakens and is hungry for it. It is easier for all concerned to feed him than to have the whole family kept awake in the effort to break him of the night feeding. The insistence of the nurse in the hospital that the baby must not have this feeding makes much trouble when he gets home and insists on having it. Many mothers struggle too hard to feed the infant exactly on the hour, night and day. In general, it is best to feed at regular hours, by day, but let the baby decide when the night feedings are due. This plan gives the whole family more sleep.

There is no single guide to the management of the feeding of any infant. The total behavior must be studied in every case. All of the signs and symptoms involved are objective, for the baby cannot offer any subjective help. So the nurse or mother who says the baby is "hungry" is merely offering her interpretation of the baby's behavior and is more likely to be wrong than right. It is one of the pediatrician's most difficult problems to convince the loving mother of a baby who cries a

little at the end of feeding that her darling is not in imminent danger of death by starvation, even when he has gained a good rate and shows all the other signs of adequate feeding.

In judging the success of any plan of feeding the following points must be noted: weekly gain in weight, vomiting, stools (number, color, consistency), eagerness for food, crying before or after feeding, restlessness, sleep, the baby's aspect, color, general nutrition, tissue turgor, and the skin. None of these points should be neglected, nor does any one of them serve as the sole index of the need of more or less food.

The normal well-fed baby gains 4 to 6 ounces a week, vomits little (though he may regurgitate with air eructations). His stools are not too many (one to four), or too large, are yellow or slightly green, and are soft and smooth. A little variation in consistency, a few curds, or a small amount of mucus means little. He takes food readily, cries lustily before mealtime for a few minutes and, perhaps, briefly when feeding is over. He is quiet between meals and sleeps most of the day and night. He is placid, has a good color, and tends to be plump, with firm tissues and a smooth clear skin.

The overfed child gains too fast (8 ounces or more a week) and soon becomes too fat. He vomits after meals from distention or, later, from indigestion. His stools are too many, too large, too loose, and more green than yellow. He cries little before meals but may do so from overdistention after feedings or from indigestion later. He often sleeps past mealtime. He may develop eczema.

The underfed child gains too little (less than 4 ounces a week), cries too long before meals, rarely vomits, is constipated, and sleeps too little. His tissues become lax and, if underfed for long, he develops malnutrition or even marasmus.

How long shall a baby nurse? Again the answer is simple—as long as the baby does well and the mother does well. The mother should nurse only so long as her physical and mental health are good and she is showing no signs of strain. In general, nursing may be profitably continued so long as the baby gets half his requirements from the mother. When the breast milk falls below this amount the end is in sight.

The mother's hygiene often needs regulation. She should have enough rest, some exercise, and an adequate diet. But she should not be allowed to stuff herself with the idea that she will produce more milk. If she can-

of immediately after delivery, the initial weight loss would be much less. If he is given a few ounces of sugar solution in the first few days, he gets along well enough. At Bellevue all babies are offered 5 per cent sugar solution every four hours in the first three days. It is surprising how little they take, often only 2 to 3 ounces a day, occasionally 7 or 8. They do not have the so-called dehydration fever even with this small amount. Citrate-lactose solutions, given by some, may cause water retention and prevent weight loss, but this is mere subclinical edema. Real edema has been produced by these solutions.

Artificial feeding in the prelacteal period, especially if too generous, may cause indigestion and serious trouble. The students of allergy believe that giving cow's milk in these early days may be responsible for sensitivity to that food later in life. But the worst feature of giving bottles before the milk "comes in" is the tendency to continue them after there is plenty of milk. Some babies have bottles that are adequate for complete feeding forced upon them after they have had all they need from the breast!

We have seen that the average, normal breast-fed infant gets only 10 to 30 calories per pound in his first week and 35 to 45 in the second. By the beginning of the third week he needs 45 calories per pound and will gain on this amount. The bottle-fed babies do perfectly well on equivalent calories, and the weight curve is identical with that of the baby on the breast. There may be a loss in the first few days, but the weight curves swing up when 30 to 35 calories per pound are taken, and there usually is a good gain in the second week on less than 45 calories per pound. These statements are based on experience in the nurseries of the Sloan Hospital for Women, the Bellevue Hospital Obstetrical Service, and in many years of private practice. Faber¹⁷ offered artificial food after the breast and found that babies *would take* 45 calories per pound by the fifth day and 52 per pound by the fourteenth day. Since babies gain on the lower amounts given above, his method must be questioned.

There is another aspect to this matter besides the mere caloric intake. The newborn baby who must be artificially fed from birth needs education to accustom him to an unnatural food. A weak formula gradually strengthened does this better than a strong one that may disagree with him. The objects to be held in mind in artificial feeding should be first, to train the baby's digestion to take

cow's milk, second, to avoid any upset at any cost, and, only last, to make the baby gain weight at a satisfactory rate.

The plan introduced at the Sloan Hospital for Women over forty years ago accomplishes these ends. It has been used by many obstetricians and pediatricians on thousands upon thousands of babies. I have tried many others but have not found a better plan. It has been used in Bellevue Hospital on the Children's Medical Service for twenty-five years and on the Obstetrical Service for over ten years. This plan gives the baby the same caloric intake in the first weeks as that obtained in normal breast feeding.

In the last few years, however, much larger quantities of food are recommended for the newborn infant. Babies are started off on formulas giving 50 to 60 calories per pound in the second day. "Standard" formulas are used in many hospitals by obstetricians who do not make the mental effort to study what they contain. The matter is too often turned over to the nurses. These standard formulas have been widely publicized in free magazines of commercial firms, by evaporated milk companies, and by the advertisements of certain carbohydrates.

The following are the standard formulas commonly used.

	Ounces	Calories
Evaporated milk	7	301
Water	14	
Sugar	1	120
	21	421
or		
	Ounces	Calories

Seven feedings of 13 ounces or six feedings of 3½ ounces

If a 7- to 8-pound baby takes all of these feedings he obtains 50 to 60 calories per pound two or three times the amount he needs in the first week.

Many infants will not take all of the large amount of food offered them, and thus saves them from digestive difficulty.* Others will

* An experience in the newborn nursery of a large private hospital is illuminating. While seeing a private patient there one of the nurses who was in charge of another baby said: "Doctor, why is it that none of these babies will take all their bottles?" At that moment five or six other nurses were all giving bottles to their charges and several of them echoed the first nurse's statement.

(Continued on next page)

of gratitude to the physician which makes her willing to continue to nurse. It does not necessarily mean the end of breast feeding.

Fig 4 shows the duration of nursing in 220 patients under my observation (see also Table 1). The solid lines indicate all breast feeding, the broken ones represent periods when one or occasionally two bottles were given. In all instances the babies obtained most of their food from the breast. The long continuation of breast feeding on this plan refutes the idea that "one bottle means the end of nursing." In my experience it helps prolong breast feeding.

When mixed feeding is necessary because the breasts will not supply enough milk, confusion sometimes arises as to whether it is better to give a supplementary bottle for one feeding or to give a complementary one after the breast. The single full bottle feeding is useful when the baby gets enough from the mother at all feedings, in order to free her for social, athletic, or other activities or to rest her once a day (when she is tired, usually at the late afternoon feeding). The complementary bottle after the breast should be used only when the baby gets too little breast milk at some feeding, although enough in the day to make it worth while to prolong nursing. It has been shown that giving complementary feedings to all babies cuts down the percentage of breast feeding.¹⁸ In using this addition to the breast, the infant should be weighed before and after nursing and then be given only so much artificial food as is necessary to make up an adequate meal. It is often necessary to do this only in the latter part of the day. Babies usually get enough in the first two nursings but may need a complementary bottle later. For instance, if a baby needs 5 ounces of milk at a feeding but gets only 1 or 2 at some, he is entitled to the difference from a bottle. One must remember the daily fluctuation in breast milk, however, and only add the bottle when the day's total is falling.

Babies are deprived of the opportunity to nurse for various reasons. The mother may be afraid of being tied down—of being kept from social engagements. She may fear the effect on her husband who wants her free for his companionship. The dread of losing their figures influences some mothers. The economic status of the family may force the mother to go to work as soon as possible. In the majority of cases she can earn less than it costs to hire, house, and feed a competent nurse! Inverted or small nipples may make nursing impossible, but with proper attention

before the baby is born most nipples can be made to function. The doctor sometimes thinks "the mother's milk might not agree" (without ever giving it a trial). In one such instance the mother's breast "caked" and there was great difficulty in drying up the milk. The artificial food disagreed and there was trouble for several months. One mother said she would not nurse because it was a "nasty animal performance." She had so much milk that she had to nurse her baby for six months—a just retribution! Of course, a mother who has honestly tried more than once to nurse previous babies without success should not be pushed further.

Weaning of babies who are started on the breast is prompted by many of the above reasons. Much more common is the following sequence. The baby nurses freely from an abundant supply, gains too fast, begins to vomit, to have loose stools, and to cry from colic. He is weaned because the "milk disagrees" and, since he is weaned during an upset, the artificial food also disagrees. All he needed was to have less breast milk. This train of events starts many difficult feeding cases. Cracked nipples occasionally necessitate weaning, but with short nursing periods a temporary use of a shield, and local treatment, weaning can usually be averted.

Failure of the supply, of course, ends the nursing eventually. This takes place in several ways. In the first group are the mothers who just cannot secrete milk. The baby gets only a few ounces a day, and nursing has to be abandoned in the first two to three weeks. The next group can give some milk for four to eight weeks but the supply is never adequate. This amount of nursing is worth while, for it enables the baby to acquire a gradual education to cow's milk. A third group nurses successfully for two or three months when the supply fails, often because the mother goes back to her normal life and in doing too much becomes overtired. The really good nurses are the mothers who have all the milk a baby needs for four to ten months and who even then find it difficult to stop nursing.

Artificial Feeding

Giving artificial food in the first days of life is a standard practice in many hospitals. The attempt to prevent the initial weight loss by this means is not necessary and may be harmful. The loss of half a pound or even more does the baby no harm. Part of the loss represents meconium and urine. If the baby were weighed after six to twelve hours instead

of immediately after delivery, the initial weight loss would be much less. If he is given a few ounces of sugar solution in the first few days, he gets along well enough. At Bellevue all babies are offered 5 per cent sugar solution every four hours in the first three days. It is surprising how little they take, often only 2 to 3 ounces a day, occasionally 7 or 8. They do not have the so-called dehydration fever even with this small amount. Citrate-lactose solutions, given by some, may cause water retention and prevent weight loss, but this is mere subclinical edema. Real edema has been produced by these solutions.

Artificial feeding in the prelacteal period, especially if too generous, may cause indigestion and serious trouble. The students of allergy believe that giving cow's milk in these early days may be responsible for sensitivity to that food later in life. But the worst feature of giving bottles before the milk "comes in" is the tendency to continue them after there is plenty of milk. Some babies have bottles that are adequate for complete feeding forced upon them after they have had all they need from the breast!

We have seen that the average, normal breast-fed infant gets only 10 to 30 calories per pound in his first week and 35 to 45 in the second. By the beginning of the third week he needs 45 calories per pound and will gain on this amount. The bottle-fed babies do perfectly well on equivalent calories, and the weight curve is identical with that of the baby on the breast. There may be a loss in the first few days, but the weight curves swing up when 30 to 35 calories per pound are taken, and there usually is a good gain in the second week on less than 45 calories per pound. These statements are based on experience in the nurseries of the Sloan Hospital for Women, the Bellevue Hospital Obstetrical Service, and in many years of private practice. Faber¹⁷ offered artificial food after the breast and found that babies *would take* 45 calories per pound by the fifth day and 52 per pound by the fourteenth day. Since babies gain on the lower amounts given above, his method must be questioned.

There is another aspect to this matter besides the mere caloric intake. The newborn baby who must be artificially fed from birth needs education to accustom him to an unnatural food. A weak formula gradually strengthened does this better than a strong one that may disagree with him. The objects to be held in mind in artificial feeding should be first, to train the baby's digestion to take

cow's milk, second, to avoid any upset at any cost, and, only last, to make the baby gain weight at a satisfactory rate.

The plan introduced at the Sloan Hospital for Women over forty years ago accomplishes these ends. It has been used by many obstetricians and pediatricians on thousands upon thousands of babies. I have tried many others but have not found a better plan. It has been used in Bellevue Hospital on the Children's Medical Service for twenty-five years and on the Obstetrical Service for over ten years. This plan gives the baby the same caloric intake in the first weeks as that obtained in normal breast feeding.

In the last few years, however, much larger quantities of food are recommended for the newborn infant. Babies are started off on formulas giving 50 to 60 calories per pound in the second day. "Standard" formulas are used in many hospitals by obstetricians who do not make the mental effort to study what they contain. The matter is too often turned over to the nurses. These standard formulas have been widely publicized in free magazines of commercial firms, by evaporated milk companies, and by the advertisements of certain carbohydrates.

The following are the standard formulas commonly used

	Ounces	Calories
Evaporated milk	7	301
Water	14	—
Sugar	1	120
	21	421

or

	Ounces	Calories
Milk	14	280
Water	7	—
Sugar	1	120
	21	400

Seven feedings of 13 ounces or six feedings of 3½ ounces

If a 7- to 8-pound baby takes all of these feedings he obtains 50 to 60 calories per pound two or three times the amount he needs in the first week.

Many infants will not take all of the large amount of food offered them, and this saves them from digestive difficulty.* Others will

take all they can get, especially if they are thirsty, and soon show the signs of overfeeding. These signs may not develop in the hospital or under the obstetrician's eye but often come on just as the pediatrician takes charge. He then gets credit for the upset, and the hospital staff goes blandly and blindly on its way, ignorant of the damage done by this early overfeeding.

In the study of Milk Station babies and of private patients, certain hospitals stand out for the too strong formulas given babies on discharge. The symptoms of overfeeding which have usually resulted are promptly relieved by cutting down the strength of the formula.

After the first two weeks, normal infants need about 45 calories per pound, and they will gain on this amount at a normal rate.* Placid and calm babies may gain on less. It is rarely necessary to give as much as 50 per pound, except to active babies. Proof of this statement also rests in the experience of many physicians through many years. Added proof will be offered elsewhere.

Here again, after the first weeks one sees enormous amounts of food prescribed for infants. The results are inevitable. Some infants develop an intractable anorexia, refuse part or all of the food offered, and may take so little that they stop gaining. The physician tries to increase the gain by giving more food or by adding fancy vitamins, usually with no success! The appetite promptly returns when the food offered is cut down—below 45 calories per pound at first—and then kept strictly to that amount. Other infants gain

rapidly on overfeeding and become extremely fat. Real obesity is undesirable at any age. Some babies develop acute digestive symptoms (vomiting, diarrhea, etc.), especially if they acquire an acute infection. Some overfed babies develop eczema, especially if there is an allergic family history. At first, this is a mild erythema of the cheeks, but it may spread rapidly to the extremities and trunk. Facial eczema humiliates the mother, but a severe universal eczema is one of the most distressing conditions seen in infancy. It carries no small threat to the baby's health or even to his life. The itching disturbs his sleep, lowers his resistance, and babies with eczema may succumb to acute infections of the skin or respiratory tract.

The proponents of high-calorie feeding often assume a calm superiority over those who recommend the older, more conservative plan. But many of us see patients whose symptoms disappear so promptly on reducing their food that it is impossible to doubt that they were caused by overfeeding. Numerous examples come to my notice each year, and more are collected by my hospital staff. A few of these have been reported.³

Overfeeding in the early months is often seen by giving solid foods too soon or in too great a quantity. While small amounts of solids (cereals, vegetables, egg, etc.) can be given early, there is no special advantage in giving them before the fourth or fifth month. Minute amounts may do no harm but really represent a mere gesture. Large amounts are not needed and, if they are forced, the baby either refuses his bottle or develops a distaste for all food. When solids are begun, the amount should be small—1 teaspoon gradually increased to 1 tablespoon. It is not necessary to give the 4 to 6 ounces often ordered at any time in the first year.

The fear of deficiency diseases and the present furor over vitamins makes some physicians feel that it is necessary to begin codliver oil and orange juice in the first days of life. It has been proved that breast-fed babies get enough ascorbic acid if the mother eats citrus fruits regularly. Orange juice or the pure vitamin may be started a week or so after

On consulting the order book it was found that the formulas all contained 50 to 65 calories per pound in the first two weeks. Wise babies to refuse part of the food offered! These formulas were prescribed by obstetricians or pediatricians who were supposed to be the best in the city. In another suburban hospital the head nurse in the nursery said that many babies were upset by the 'standard' formula and the food had to be reduced. Yet, the formula remained as a routine in spite of the protests of the pediatrician.

* A simple method of writing a formula containing 45 calories per pound is to give 35 calories of milk, $1\frac{1}{4}$ ounces per pound, 10 calories of sugar, $\frac{1}{4}$ ounce per pound. Water is added to make a total of 3 ounces per pound in the early months and 2 ounces per pound in the later months.

weaning, but there is no great hurry Scurvy does not develop overnight

The normal baby who can get sun on his skin needs no codliver oil except in the dark winter months The premature or weak infant may aspirate oil and die of pneumonia Drisdol is the best form of vitamin D for small infants for this reason But rickets is not an acute danger in the early days of life, and one can wait a week or two before beginning any preventive

Summary

Breast milk is the normal, natural, and best food for the young infant Ninety per cent of the mothers of all classes can nurse their babies when properly managed and supervised

Artificial feeding should be based on the amount of food obtained from the breast Babies do perfectly well on low calories per pound in the early weeks Weak formulas, gradually made stronger, educate the young infant to artificial food which is more important than a rapid early gain Overfeeding in the early months, especially in the neonatal period, is a dangerous practice, for it may result in acute digestive upsets, eczema, or an intractable anorexia Some babies merely get too fat, but obesity is not desirable at any age

Discussion

Dr George R. Murphy, Elmira, New York—As a former student of Dr Smith's, I am fairly familiar with his views on feeding and can usually agree with much that he has to say

My own experience in charge of the newborn services at each of the two hospitals in Elmira for the past twelve years has brought out certain definite points. Between the two hospitals there has been an annual total of births from around 881 in 1930 to 1,203 in 1940 Incidentally, all but 18 babies born in Elmira last year were delivered in the hospitals Of course, our jurisdiction is limited to those children born on service and our own private patients However, through our control over the routine nursery procedures, we are able to exert influence on the other private patients

For instance, it is routine for all babies to receive (a) plain water, (b) beta lactose-sodium citrate solution, or (c) 5 per cent glucose during the first twenty-four hours and to offer one of these *post cibum* until the breast milk is established If there are no contraindications to nursing, the baby is put on breast feeding at the end of twenty-four hours for two minutes on each side every four hours The time at the breast is increased each day two minutes up to a total of eight to ten minutes on each breast, both breasts at each feeding, at the end of four or five days By this time most mothers have established their milk supply The mothers are encouraged to help by manual expression of the breast during nursing and by pumping dry at the end of the nursing The only thing a baby gets in addition to the above during this period is 1 mg of synthetic vitamin K during the first six hours postpartum.

It must be admitted that one has to check on the nurses, especially the night force, fairly carefully or they will give a crying baby 50 per cent milk no matter what is causing the crying! Also it must be said of those babies not under our care, a fair number are "weaned" on the second or third day "because there is no milk." This, despite the fact that everyone knows breast milk "comes in" between the second and fifth days When the milk supply has been established, if it appears to be insufficient, we may complement the feeding For this we usually use Droyco, with instructions to make it up as needed

We make no attempt to put babies on breast feeding where the mother's condition does not warrant an added strain, where her past nursing history has been unfavorable, where there has been a long period between pregnancies, or where her age (near 40 years) suggests that such efforts will be unsuccessful—unless she insists Occasionally, one of these latter women will surprise us with a successful nursing We used to attempt to use a pump to "pull out" inverted nipples but have stopped We used to argue with the women who refused or did not want to nurse, but we have stopped this We are es-

pecially reluctant any more to ask doctors' wives to nurse because they "seem" unable

The only addition to the maternal diet which we suggest, besides adequate intake of food and of fluids, is some preparation with the B complex such as Chocolate Vitavose or Cal-C-Tose. We do find mothers drinking large quantities of fluid at the expense of the solids, hoping it will go from the mouth to the breast. Sometimes it does and dilutes her milk.

The problem of the cracked nipple is a common one. We still favor alcohol, or tincture of benzoin, Citrox, or the B D Nipple Shield, which is really an air-conditioner. The towels bound around the breasts frequently cause extrusion of milk and, by friction, produce maceration of the nipples.

For the baby who is to be artificially fed, we are interested in the family history of allergy, if present. We usually start with 50 per cent milk and, if after twenty-four to forty-eight hours the baby handles it well, we start building up the formula toward the theoretic requirements. Generally speaking, we favor an irradiated evaporated milk, 1 part, water, 2 parts, and 1 ounce, carbohydrate—usually beta lactose. This is the easiest and one of the cheapest formulas to prepare which we have used. It has one disadvantage—one cannot skim off any of the fat. With a vomiting baby, we switch to ordinary cow's milk in a formula boiled three minutes. The evaporated milk also has the advantage of being less constipating than cow's milk.

We insist on babies being held nearly upright on feeding. We also like to have them empty their bottles within ten minutes, as they swallow less air. To aid in this respect, all our nipples are prepared according to the suggestion of an Englishman writing in the *Archives of Pediatrics* about two years ago.* A cross is cut in the top of a new nipple with a razor blade. The two lines of the cross are each $\frac{1}{8}$ inch long—to complete the cut through the nipple a Bard Parker No 11 knife is used. This nipple allows for free flow of milk on the slightest suction by the baby, but the flow stops as soon as the baby stops sucking. This latter advantage precludes choking when the baby stops to take a deep breath or to look around the room. We have used fewer nipples since cutting them this way. The

*Wikin, M. *Arch Pediat* 56 No 2 (Feb) 1939

old method of enlarging the holes wasted many nipples by making the holes too large.

Fortunately, we have had no experience with epidemic diarrhea of the newborn. This undoubtedly is mostly good luck, although we think aseptic technic may be responsible in part. No one is allowed in the nurseries except the nurses assigned there, the intern on obstetrics, the cleaning woman, and the attending physician. All persons entering the nursery must wear mask and gown. In one hospital the nurses scrub between each baby. In the other, they use the technic advocated by R. G. Flood in the *American Journal of Diseases of Children*, November, 1939. His technic requires the baby nurse to scrub thoroughly on entering the nursery. Then she soaks her hands for a slow count of 10 in 5 per cent Lugol's solution and decolorizes in saturated sodium theosulfate solution. She repeats the soaks between each baby. All doctors entering the nursery are required to put on sterile rubber gloves before touching any baby. At feeding time, mothers are required to wear masks and wash their hands before feeding the child. The breasts are also cleansed if the baby nurses. And no visitors are allowed with the mother while the baby is being fed—not even its father.

In conclusion, let me emphasize the importance of written or printed instructions to the mother. The attention paid to the small details is repaid over and over in the supervision of the baby. We try usually to have our mothers read Dr. Aldrich's book *Babies Are Human Beings* in order to dispell the fears produced by the folklore that has been built up by grandmothers and maiden aunts. One of the primary purposes of a pediatrician, as I see it, is to encourage mothers and to avoid creating an over-anxious atmosphere.

Dr. Charles Hendee Smith (*Concluding Remarks*)—May I point out that the formulas used by Dr. Murphy for the newborn are stronger than we consider necessary. I have seen many babies upset seriously by a "50 per cent milk mixture" in the first week. We never give this strength until the end of the second week. Moreover, the mixture with evaporated milk 1 part and water 2 parts is even stronger. These are the "standard formulas" to which I object so strongly.

PETER RABBIT, TOM SAWYER TO REPLACE JUSTICES

that is, if Mayor La Guardia of New York City, has his way. The Mayor said that he will be happy indeed when he hears that the justices in children's courts are out playing golf—that they have nothing to do. The occasion for this speech was the opening of a library shelf for delinquent children. The committee for the selec-

tion of suitable books for children in the courts chose, among others, *The Tale of Peter Rabbit*, *Treasure Island*, *Robinson Crusoe*, *Adventures of Tom Sawyer*, and *Aesop's Fables*—all bound in gay colors. When a justice recommends a certain book for an errant child the library will see that he gets a copy.

THE MEDICAL AND SOCIAL CHALLENGE OF ALCOHOLISM

EUGENE N. BOUDREAU, M D, Syracuse, New York

WITH the question of prohibition settled by the voters of this country of ours, the public as a whole gives little further notice to the question of what happens in the mixture of alcohol and human living. But we physicians know that alcoholism still remains a problem because we all view it with such tragic frequency. We see this disastrous combination of alcohol and human living in all its hideous consequences—shattered prospects, blighted homes, mothers' despair, wives' shame, crumbled faith of children, and the individual's own misery.

Alcoholism, I believe, is a major health problem. It is a cancerous condition in our social fabric which must be resisted or controlled if we are fully to prepare our social structure for the inevitable impacts to come in this critical period of world history. Drinking alcohol leads in frequent instances to alcoholism. Let us then consider alcoholism with the object of analytically breaking down the problem into its various aspects.

But first, for clarity of thinking, I would ask you to consider alcoholism as a medical problem and, in defining it, I would have you disclaim and eliminate any ethical or moral qualifications and accept the fact that it is a malady—a sickness. For a working definition I would have you consider alcoholism as such continuous and immoderate drinking of alcohol as to produce bodily changes that undermine or destroy the physical health of the individual and promote a disorganization of his psychology or personality integration, unity, and balance. Then, as a medical concept we can consider it as to incidence, etiology, pathology, clinical symptoms, its social implications and, finally, its treatment.

Incidence

It is somewhat difficult to know the actual incidence of alcoholism in the population as a whole, but we may gain some appreciation of its frequency by surveying the frequency of hospital admissions due to acute alcoholism, the psychoses due to alcohol, and deaths ascribed to it.

By a graph (Fig. 1) Jolliffe shows the rates of admissions at Bellevue Hospital from 1902 to 1935. It is evident from a study of this graph that there was a rise of admissions to a "high" in 1910. Following that through the

succeeding years to 1919, a steady decline is manifest. Remarkably, in 1919, 1920, and 1921, at the onset of the prohibition period the admission rate shows a fall to about 2,000 as compared to 11,000 at the high period of 1910. Then following these years the admission rate again increased in a rapid and steady rise to 1935.

In a second graph (Fig. 2) Jolliffe presents the relative rates of admission of male and female patients to Bellevue Hospital for the same period 1902 to 1935. Here again, we see the striking gradual fall in ratios from 1909 to 1919 and a low period at the onset of prohibition. It is to be noted that the ratios for female admissions maintain a relatively lower rate to male admissions and quite exactly parallels the fall and rise in male ratios before and after prohibition. It is common knowledge that drinking is less in the general population among women. It can be fairly assumed that, therefore, this is the chief reason for fewer admissions for acute alcoholism among women.

Fig. 3 shows graphically the admissions to the Civil State hospitals of New York State between 1909 and 1931. Here again, we see that these admissions dropped steadily from 1911, or thereabouts, to 1920 and 1921 and, thereafter, rose again to 1931. Also, female admissions were lower but kept a relative ratio with the male admissions during the falling and rising periods.

From Table 1 it is evident that alcoholic psychoses have a lesser incidence in rural than in urban populations. In the latter it is generally accepted that drinking is more common, therefore, this tabulation also shows that the greater the drinking among our population the greater the incidence of alcoholic maladies. The figures here also are notable in showing the decrease of the alcoholic psychoses during the years 1919, 1920, 1921, and 1922.

Table 2 likewise indicates the fall of first admissions for alcoholic psychoses during the years 1919, 1920, and 1921 especially, also a decline from 1911 through 1920, then a steady rise thereafter.

Table 3 indicates the common age incidence of alcoholism and shows that it is found in all walks of life or in the various social levels of society.

FIG 1 Total alcoholic admissions, 1902-1935 Norman Jolliffe Science 83 No 2152, 307 (March 27) 1936

Table 4 shows figures obtained from the United States Bureau of Census and reveals deaths from alcoholism during the years in which we have been interested. This shows a striking diminution of these deaths during the years when drinking was less general, especially through 1919 to 1922.

In 1938, quoting from the report of the Department of Mental Hygiene of New York State, of total admissions of 16,070 to Civil State hospitals, 2,072, or 12 per cent (of which 1714 were men and 358 women), were designated intemperate in the use of alcohol. In the same year there were 831 admitted with alcoholic psychoses, about 5 per cent of the total admissions.

It is strikingly proved, I believe, by these statistics that in periods where general drinking decreased the incidence of deaths from alcohol and hospital treatment for various grades of alcoholism diminished and when drinking increased these conditions promptly increased.

As Jolliffe¹ pointed out in his Bellevue report, the pressure of social opinion became more and more emphatic from 1909 to 1919, leading to diminished drinking and then to the adoption of the prohibition amendment. It was in this decade that our statistics showed decrease. Then came the "great revolt" against the limitation of our personal liber-

ties, followed by the hip flask, bootlegging and, finally, repeal. During these last two decades again, the incidence of alcoholism as indicated by hospital admissions has increased to the original volume.

One is rather overwhelmed by statistics referred to in a book entitled *Alcohol—One Man's Meat*, by Strecker and Chambers in 1938.² Dr Strecker is professor of psychiatry at the University of Pennsylvania. Let me quote their statements: "Statistics not yet thoroughly checked are alarming. Drinking seems to be rapidly increasing among young people. A report of one insurance company indicates that the proportion of rejections, 'involving heavy alcoholic indulgence' in the age group under 30, in 1936, was almost three times the proportion in 1932.

"The percentages are as follows:

April 1, 1931, to March 31, 1932—11.9 per 100	} Increase, 183 per cent
April 1, 1934, to March 31, 1935—29.7 per 100	
April 1, 1935, to March 31, 1936—33.7 per 100	

"This table includes only cases of indulgence sufficiently heavy to be a factor in rejections."

† Includes nine months due to change in fiscal year

‡ Estimated for twelve months

cate that I have treated 69 cases of alcoholism, as noted in Table 3. In the same time I treated 291 cases of other mental and nervous ailments. The incidence of alcoholism from these statistics was 2.37 per cent. However, this number of alcoholic addicts represents, I should estimate, less than a fourth of all cases that have come to my attention through the solicitations by relatives for advice and professional assistance. Such assistance was sought for individuals who had evaded proffered help by refusing to submit to hospital care, believing they do not need it and could care for themselves, or had so depleted their resources that they could not afford the cost of the treatment.

Etiology

In my experience it takes eight to ten years of drinking to make a helpless addict. Of these eight or ten years it is the drinking of the final two to three that is of such sort as to make the affliction noticeable to friends and associates. Though usually the victim is the first one to realize the enslavement, he refuses to acknowledge it. Instead, he fights it helplessly, making good resolutions only to find them broken after he comes to full consciousness after the next debauch, which now is always carried to the saturation point unless interrupted by some external interference from family or friends. The vicious cycle of good resolutions, overwhelming demand, saturation, feeling of defeat, demor-

alization, and loss of self-respect repeats itself more and more frequently and lasts longer and longer until either he or his friends or relatives seek help in desperation. It is remarkable how regularly this story is repeated in the history of these unfortunates. What is the explanation? I am convinced there is a deep-seated factor that is elusive and not as yet discovered. However, I have this hypothesis: Individuals have three types of reaction to alcohol. There is a group for whom alcohol has no appeal—it plays not the slightest role in their lives. It is wholly outside their sphere of interest.

A second group takes alcohol over long periods of their lives, moderately usually, and seems never to have the tendency to go further. The third group also drinks, at first moderately but gradually less and less moderately, and inevitably becomes enslaved by the drug to pursue the course of the vicious cycle.

TABLE 3 — ADMISSIONS TO TWIN ELMS FOR ALCOHOLISM FROM SEPTEMBER 1 1929 TO OCTOBER 1 1939

Sex		Occupation

† Excludes deaths of soldiers, sailors, and marines.

above defined. It is clear that this group never should have taken alcohol at all. The inherent quality in this group of individuals which makes them vulnerable is as yet not fully defined.

My experience with them is that they uniformly are all temperamentally alike, they are most agreeable socially and they have an appealing personality. They are genial, companionable, kindly, and affable in social relationships, with a host of friends. They are soon welcomed wherever they may be. In their turn they desire social contacts and are restless, busy types—commonly, the extrovert. One is usually impressed by their intelligence and their inherent worth. They often come from the successful group of those who have done things until they are defeated by their slavery. When they have arrived at this state, it is fully apparent that they should never have used alcohol at all. And this is the crux of the whole matter.

Another apparent observation is that a number of such addicts, at present and for the past few years, began their drinking at college or in their early twenties during the earlier prohibition era. They were then in the age to be impressed and moved by the mode of surreptitious drinking and the "smartness" of it—the "fancy hip flask era." When I am approached by a wife, husband, or parent who is struggling with this problem in his family, I silently guess that he or she is from 35 to 45 years of age and this is usually correct. We are reaping the crop of prohibition-made drinkers. I am convinced that each generation since 1919 has had its crop of drinkers. It probably was also true before 1919, though now the harvest seems more ample.

Pathology

To attempt in this part of the discussion any degree of detail would be too burdensome upon you, but not to dwell upon some of the facts would be to lose some emphasis in the discussion attempted in this paper. The material here presented is taken from that part of *Alcohol and Man*, edited by Dr. Haven Emerson,³ devoted to "Chronic Alcoholic Poisoning," written by Dr. Harrison S. Martland, chief medical examiner of Essex County, New Jersey.

First, Dr. Martland points out that the fatty infiltration, especially of the heart and liver, commonly ascribed to alcohol may be found as well in obese persons who have developed their obesity from excessive eating and little exercise. For the same reasons the

same condition, of course, may be present in individuals who overindulge in alcohol. It is known, on the other hand, that chronically alcoholic persons who have an increased metabolic rate and do hard work may have organs that are in comparable states to abstainers of similar age. Therefore, fatty infiltration is not inevitably due to alcohol.

Alcohol produces its main damage in the central nervous system and peripheral nerves. However, Mott⁴ states "there is no specific lesion of the brain in acute or chronic alcoholism," though in chronic alcoholic cases the delicate covering of the brain shows a cloudy opaque and swollen state. The brain may be shrunken, the folds narrow, the fissures deep, and the vital gray layer thin, in delirium tremens the brain tissue is soggy, swollen, and pale. I should add here that Alexander of Harvard has shown by the incinerating method of microscopic study that an appreciable layer of calcium is found deposited beneath the outermost layer of the brain. These calcium or bonelike deposits cannot be dissolved away by natural repair.

Mild degrees of inflammation of the nerves are common in chronic alcoholism. In Korsakow's psychosis, frequently associated with such neuritis, sometimes there is found a multiplication of small blood vessels and an overgrowth of supporting tissues in the brain.

Chronic inflammation of the lining of the stomach with definite structural changes may be found, and Boyd⁵ states that in over 50 per cent of all alcoholic patients this may reach a stage of loss of the important glands and result in the absence of hydrochloric acid in the gastric juice.

Norris⁶ states that a fatty liver is the lesion that is chiefly associated with chronic alcoholism.

Fatty infiltration of the liver in alcoholism represents an increased or abnormal storage of fat in the liver cells, the result of the general obesity from the nonutilization of other food-stuffs occurring when alcohol is oxidized in the body.

Cirrhosis of the liver, "hobnail liver," is found in 4 to 6 per cent of all chronic alcoholic patients. Fifty to 60 per cent of all cirrhosis of the liver occurs in chronic alcoholic cases.

The kidneys apparently suffer little from alcoholism.

Clinical Data

As we develop the clinical history of these patients, there are some fairly uniform clinical facts revealed. As the years of drinking ad-

vance, noticeable personality changes become evident. There grows a progressive self-centeredness, an apparent selfishness, and a dulling of the sensibilities. The individual becomes less considerate. He loses his capacity for business and is negligent or impatient because of his preoccupation with his avocation of drink. He becomes irritable, rigid in his ideas and social attitudes, or he may begin to show excessive sensitiveness or paranoid tendencies. Later, he becomes obtuse, his moral and ethical values change, and he gets into unfortunate difficulties with his business associates, his employers, or business clientele. His behavior, when called to his attention, he blandly excuses with evident unconcern.

Beyond this in grades of disorders due to severer alcoholism are delirium tremens, alcoholic hallucinosis, and Korsakow's psychosis. Delirium tremens is an acute confused state with predominant visual hallucinations. A more prolonged disorder is the alcoholic hallucinosis, which is characterized by paranoid delusional formation and hallucinations, usually of hearing. The most severe and hopeless disorder is the Korsakow's syndrome. Here is a profound condition of mental changes in which the memory is all but gone and is replaced by fabrications of bizarre character in the mental production. There are also associated extreme grades of polyneuritis.

Social Aspects

Those of us who lived our early lives before the first World War period know that in that period the attitude toward drinking was quite different than following it. Then, it was decidedly not common to feel the need of serving "drinks" at a home gathering. In business the mode was not to "high pressure sales" by way of dinners, drinking, and night clubs. Rather, employees in business were carefully scrutinized as to their drinking habits. In college there were rare beer parties, but a college social function was scandalized by a "lit" college man. A college woman who drank was unheard of and unconceivable. Then came the war and prohibition. The "he-man" rose up in righteous indignation at the challenge to his personal liberties and started to "show the world." He talked and acted so vigorously or belligerently as to make it seem quite effeminate not to show one's "backbone" by carrying a hip flask. Soon the high school children were doing it, as well as college girls

and boys. I know even of an instance of a mother who gave her 16-year-old daughter a flask as she was going to a party so that she would not be endangered by poisoned bootleg liquors. The mode spread to locker rooms and bridge tables.

Thus, in a relatively few years I should say, we lost the benefits derived from some fifty or more years of what was really preventive medicine, though it was unfortunately often in the guise of moral or religious propaganda.

All good medical authority recognizes that alcohol in immoderation reduces the efficiency of the individual, as well as dulls his ethical and moral sensibilities, and makes him less and less a social and economic asset. In business he becomes a hindrance to an organization from the changes slowly wrought in his personality before it is recognized. Adolf Meyer phrases it as follows: "Alcohol does much of its harm by its relatively insidious, apparently insignificant effects on the management of individuals and social life. It is difficult to say where the definitely conspicuous effects in the production of clearly pathological consequences begin. The usual effects of alcoholized sociability and their lowering of standards can be more or less covered up and made up for. At any rate, they may disappear in the immediate gain of gratification and joviality and the reduction of tension and any burdensome sense of responsibility, but usually at the expense of ultimate performance and of the family budget and of interest in more far-reaching civic enterprises, of provisions for education, of the cultivation of amusements free from alcohol, and of the general standards of social life." He also says "Any easy method of escaping responsibility implies a lowering of standards and avoidance of effective solution."

The greater the multiplication of individual instances of alcoholism, the greater the weakening of the social fiber of a community. The wastage in living is intangible and incalculable, but nevertheless positive and lamentable.

Treatment

In the individual case the treatment is often discouraging in its results. Yet the need for treatment is so challenging that we must accept the challenge, for there is no other source of help that can give as much as the medical man. However, we are greatly limited because the essential cause is not known and

may be so deep-seated in the personality constitution of the individual as to hark nearly all effort. However, striking benefits can frequently be attained, which is the only encouragement we have.

The only known methods that give any lasting results aim to attain capacity for total abstinence. This involves complete control of the sufferer by residence, for a time, in a special hospital where complete surveillance is maintained. I have established the rule that acceptance of each problem is conditioned upon willingness to submit to a minimum period of treatment of six weeks. The effort then is directed toward three objectives: first, "detoxication" or elimination of the effects of alcohol, second, physical rebuilding by healthy living, good food, and graduated physical exercise, and, third, complete psychiatric survey of the personal problems and essential psychic conflict. Each individual is led to the appreciation of the extent of these conflicts upon himself, he is then helped in the reformulation of his attitudes toward them, and proper adaptation to them is outlined for him. Finally, he is led to appreciate fully the price he pays in life's values for his overindulgence.

The real approach to this problem, I believe, is through prevention, and the way to this must be by social effort directed to mass education. This movement can best be led by the medical profession. A sustained campaign in this direction is assuredly an effort in preventive medicine, which the statistics I have presented fully justify. The statistics fully illustrate and emphasize that generally less drinking and fewer drinkers mean fewer alcoholic victims, and the only effective means to promote less drinking is to develop a strong social attitude against drink-

ing. An attitude that reduces the lightness and the carelessness of our present views relative to drinking must be attained. Happily, there are again some recent indications that the younger members of society are drinking less, but unfortunately that does not seem to have been promoted by the example of us elders, unless it is that that example has been to disgust the youth and make him determined to do a better job with this social problem than we did.

Conclusions

In ending, let me emphasize what conclusions this discussion endeavors to prove.

1 Alcoholism is a medical problem of great magnitude.

2 Our profession should accept the challenge, seek by research for the complete medical solution and, above all, afford leadership in a social movement against drinking. More drinking inevitably is followed by more addictions and other alcoholic disorders.

3 Each generation of drinkers has cases that are eventually bound to become addicts, if they drink at all.

4 Addiction promotes economic loss, social decay, and untold suffering and sorrow.

ARMY COLD WEATHER HEADGEAR

The results of experiments on clothing for cold climates made during the Byrd Antarctic expeditions have been used in the designs of new headgear for soldiers, standardized by the Army Quartermaster Corps, the War Department has announced. An olive-drab knitted cap, a stocking cap, and a cloth hood designed for protection of the head and neck will be used by soldiers this winter.

Adapted from the Eskimo parka for Army use, the hood is made of wind- and water-resistant poplin. Tightening a drawstring brings the hood together in front to cover almost the entire face. The attached shawl protects the back of the

soldier's head and fits down over the top of his shoulders.

The new cap, which may be worn up over the ears, includes a snug shawl which may be turned down to protect the ears and neck.

During his Antarctic experiments, Dr. Paul Siple developed a formula to measure the effects of wind on the heat loss of the body. He found that whereas a person wearing only a medium heavy sweater is reasonably warm at zero temperature he quickly becomes cold if there is a wind of even 10 miles an hour velocity, because his heat loss increases in proportion to the increase in the velocity of the wind.—J A M A

BLEEDING AS A LATE SEQUELA OF GASTROENTEROSTOMY AND SUBTOTAL GASTRECTOMY OF THE BILLROTH II TYPE FOR DUODENAL ULCER

SIGMUND MAGE, M D , and RALPH COLP, M D , New York City

DUODENAL ulcer, as a rule, responds favorably to medical therapeutic measures. It becomes a surgical problem when such treatment fails to relieve pain, when gross hemorrhages of a severe degree are repeated, and when a pyloric stenosis persists or an acute perforation occurs. If surgery is indicated, various procedures are available. There are, however, two main operative approaches: one the more conservative procedure of gastroenterostomy, the other, the more radical subtotal gastrectomy.

There is no doubt that gastroenterostomy usually heals a duodenal ulcer, and in the majority of cases the patients are relieved of their symptomatology. However, not infrequently, a more serious train of symptoms may follow. This is due, in most instances, to the development of jejunal or gastrojejunal ulcerations. The incidence of this untoward and serious complication following gastroenterostomy varies in different clinics. However, as the refinements of diagnosis have become better and patients have been followed more carefully and for longer periods, the incidence of jejunal and gastrojejunal ulcerations has assumed increasing proportions. These complications have been observed to occur as soon as a few weeks and as late as twenty-five years after the primary operation has been performed.

In an effort to avoid these unfavorable sequelae of gastroenterostomy, the operations of Billroth I and II type of subtotal gastrectomy were introduced two decades ago for the treatment of gastroduodenal ulceration. While the former procedure has enjoyed great popularity on the Continent, the modifications of the Billroth II type of resection have been used almost exclusively in the surgical clinics of this country. The advocates of subtotal gastrectomy stressed the importance of the acid factor in ulcer pathogenesis and contended that jejunal ulcerations followed gastroenterostomy because that operation failed to control the secretion of free HCl in the stomach. It was argued that since peptic

ulceration seemed to occur in the presence, and not in the absence, of free HCl the creation of a gastric anacidity should be a reasonable means for the prevention of a recurrence. When subtotal gastrectomy was first proposed, the resection of the pylorus and antrum was expected to effect a gastric anacidity because it removed the antral-stimulating influence on the acid-secreting fundic glands. Physiologic studies have revealed that the removal of the antral stimulus affects only the gastric phase of gastric secretion. Theoretically, a subtotal gastrectomy, therefore, should diminish but not necessarily eliminate the secretion of free HCl. Experience has shown this to be actually so. For some undetermined reason the operation seems to bear out its anticipated effects with gastric ulcer but not with duodenal ulcer. There are many patients who, after a Billroth II operation for duodenal ulcer, still secrete free HCl in appreciable amounts. These patients are, therefore, candidates for further trouble. Some develop jejunal or gastrojejunal ulcerations manifested by hemorrhage, with or without pain. It is this bleeding, occurring as a late sequela of gastroenterostomy and subtotal gastrectomy, which will form the basis of this communication.

Recently, Ginzburg and Mage¹ reviewed 88 cases in which partial gastrectomy had been performed for the relief of recurrent symptoms after gastroenterostomy for duodenal ulcer. The pathologic findings in the resected specimens were correlated with the clinical history and radiologic findings. Certain significant observations were made in a group of 15 patients in whom hemorrhage was a prominent symptom. These cases do not represent the total number of such cases seen in our clinic. They merely comprise a group in which the pathologic studies of the resected specimens not only offered an insight into the nature and sources of bleeding after gastroenterostomy for duodenal ulcer but also suggested a basis for therapy.

In this group there were 14 men and one woman. Their ages were divided equally between the third, fourth, and fifth decades. The hemorrhages occurred at intervals varying from a few months to eighteen years after

ARMY COLD WEATHER HEADGEAR

The results of experiments on clothing for cold climates made during the Byrd Antarctic expeditions have been used in the designs of new headgear for soldiers, standardized by the Army Quartermaster Corps, the War Department has announced. An olive-drab knitted cap, a stocking cap, and a cloth hood designed for protection of the head and neck will be used by soldiers this winter.

Adapted from the Eskimo parka for Army use, the hood is made of wind- and water-resistant poplin. Tightening a drawstring brings the hood together in front to cover almost the entire face. The attached shawl protects the back of the

soldier's head and fits down over the top of his shoulders.

The new cap, which may be worn up over the ears, includes a snug shawl which may be turned down to protect the ears and neck.

During his Antarctic experiments, Dr. Paul Siple developed a formula to measure the effects of wind on the heat loss of the body. He found that whereas a person wearing only a medium heavy sweater is reasonably warm at zero temperature he quickly becomes cold if there is a wind of even 10 miles an hour velocity, because his heat loss increases in proportion to the increase in the velocity of the wind.—*J. A. M.* 4

BLEEDING AS A LATE SEQUELA OF GASTROENTEROSTOMY AND SUBTOTAL GASTRECTOMY OF THE BILLROTH II TYPE FOR DUODENAL ULCER

SIGMUND MAGE, M D , and RALPH COLP, M D , New York City

DUODENAL ulcer, as a rule, responds favorably to medical therapeutic measures. It becomes a surgical problem when such treatment fails to relieve pain, when gross hemorrhages of a severe degree are repeated, and when a pyloric stenosis persists or an acute perforation occurs. If surgery is indicated, various procedures are available. There are, however, two main operative approaches: one the more conservative procedure of gastroenterostomy, the other, the more radical subtotal gastrectomy.

There is no doubt that gastroenterostomy usually heals a duodenal ulcer, and in the majority of cases the patients are relieved of their symptomatology. However, not infrequently, a more serious train of symptoms may follow. This is due, in most instances, to the development of jejunal or gastrojejunal ulcerations. The incidence of this untoward and serious complication following gastroenterostomy varies in different clinics. However, as the refinements of diagnosis have become better and patients have been followed more carefully and for longer periods, the incidence of jejunal and gastrojejunal ulcerations has assumed increasing proportions. These complications have been observed to occur as soon as a few weeks and as late as twenty-five years after the primary operation has been performed.

In an effort to avoid these unfavorable sequelae of gastroenterostomy, the operations of Billroth I and II type of subtotal gastrectomy were introduced two decades ago for the treatment of gastroduodenal ulceration. While the former procedure has enjoyed great popularity on the Continent, the modifications of the Billroth II type of resection have been used almost exclusively in the surgical clinics of this country. The advocates of subtotal gastrectomy stressed the importance of the acid factor in ulcer pathogenesis and contended that jejunal ulcerations followed gastroenterostomy because that operation failed to control the secretion of free HCl in the stomach. It was argued that since peptic

ulceration seemed to occur in the presence, and not in the absence, of free HCl the creation of a gastric anacidity should be a reasonable means for the prevention of a recurrence. When subtotal gastrectomy was first proposed, the resection of the pylorus and antrum was expected to effect a gastric anacidity because it removed the antral-stimulating influence on the acid-secreting fundic glands. Physiologic studies have revealed that the removal of the antral stimulus affects only the gastric phase of gastric secretion. Theoretically, a subtotal gastrectomy, therefore, should diminish but not necessarily eliminate the secretion of free HCl. Experience has shown this to be actually so. For some undetermined reason the operation seems to bear out its anticipated effects with gastric ulcer but not with duodenal ulcer. There are many patients who, after a Billroth II operation for duodenal ulcer, still secrete free HCl in appreciable amounts. These patients are, therefore, candidates for further trouble. Some develop jejunal or gastrojejunal ulcerations manifested by hemorrhage, with or without pain. It is this bleeding, occurring as a late sequela of gastroenterostomy and subtotal gastrectomy, which will form the basis of this communication.

Recently, Ginzburg and Mage¹ reviewed 88 cases in which partial gastrectomy had been performed for the relief of recurrent symptoms after gastroenterostomy for duodenal ulcer. The pathologic findings in the resected specimens were correlated with the clinical history and radiologic findings. Certain significant observations were made in a group of 15 patients in whom hemorrhage was a prominent symptom. These cases do not represent the total number of such cases seen in our clinic. They merely comprise a group in which the pathologic studies of the resected specimens not only offered an insight into the nature and sources of bleeding after gastroenterostomy for duodenal ulcer but also suggested a basis for therapy.

In this group there were 14 men and one woman. Their ages were divided equally between the third, fourth, and fifth decades. The hemorrhages occurred at intervals varying from a few months to eighteen years after

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the surgical service of the Mount Sinai Hospital.

gastroenterostomy, and in 5 patients there was a free interval of more than ten years. Most of the group had several episodes of melena or hematemesis, and in 6 cases the bleeding was severe enough to reduce the hemoglobin below 30 per cent.

All these patients were treated conservatively during the acute phase of hemorrhage, operations being deferred until there was a quiescent period.

These 15 patients may be further divided into two groups: one in which hemorrhage was the sole symptom and another in which the bleeding was preceded, accompanied, or followed by ulcer symptoms—especially pain.

Painless Bleeding After Gastroenterostomy

There were 6 patients in whom the presenting complaint was hemorrhage without pain, and in 4 of these cases the bleeding was most severe. It is interesting to note that the x-ray findings showed evidence of a jejunal ulcer in only 1 case, while the resected specimens revealed either superficial healing gastrojejunal or jejunal ulcers. It must be borne in mind, however, that these patients were operated upon only after prolonged bed rest and medical treatment. It is not unusual to observe a similar pathology in specimens obtained from a gastrectomy in cases of primary duodenal ulcers which have received comparable preoperative treatment. The ulcerations in this type of case, too, are superficial and show no tendency to penetrate into adjacent vessels.

Bleeding After Gastroenterostomy Associated with Pain

There were 9 cases in which bleeding was associated with pain, and in 5 of these the hemoglobin fell below 40 per cent. The pain was of a severe type, which had grown more and more intractable. In spite of thorough ulcer therapy, the surgical explorations disclosed evidences of active disease, and the resected specimens revealed penetrating ulcerations of either the jejunum or gastroenteric stoma without tendency toward healing.

Bleeding After Subtotal Gastrectomy (Billroth II)

Since 1923 we have followed for a year or longer over 429 ward patients in whom a duodenal ulcer was the original lesion and upon whom a subtotal gastrectomy (Billroth II) was performed. Eighteen of these patients

are known to have experienced gross hemorrhages, i.e., either melena or hematemesis. The clinical features of these cases, which closely simulate those following gastroenterostomy, may likewise be divided into two groups: bleeding, without and with pain.

Painless Bleeding After Subtotal Gastrectomy

There were 13 patients in whom bleeding was the sole symptom. The hemorrhages occurred at intervals varying from a few months to 12 years after operation and varied from a moderate to a severe degree, the hemoglobin falling below 30 per cent in 4 patients. Eight of these cases had experienced gross hemorrhages of a severe degree prior to subtotal gastrectomy, and in 4 cases there had been more than one episode. Three of the cases with multiple bleedings before gastrectomy bled several times after operation at varying intervals. All cases responded to conservative therapy. After the acute symptoms had subsided, certain diagnostic procedures were instituted. Gastric analyses revealed free HCl in appreciable amounts in the 12 cases in which such studies were made. The x-ray examination was negative in 9 patients. However, the roentgenogram showed that a jejunal ulcer was present in 1 and that a lesser curvature gastric ulcer was present in 2 other cases. The twelfth case, in which a gastrojejunal ulcer was shown in a previous x-ray examination and in which active ulceration was seen by gastroscopy, presented a healed lesion subsequently at the time of secondary exploration.

Bleeding Associated with Pain Following Subtotal Gastrectomy

There were 5 cases. The hemorrhages occurred at intervals varying from a few months to three years after operation and were severe enough in 3 patients to reduce the hemoglobin below 40 per cent. Two of the cases, which had had pain with severe hemorrhages prior to subtotal gastrectomy, had a prompt recurrence of these symptoms after the operation. Free HCl of high concentration was present in the gastric analysis of all cases, and x-ray studies revealed evidences of jejunal ulcers. These patients, with tangible evidences of penetrating jejunal ulcers, remained intractable to medical therapy.

In 2 cases, surgical exploration disclosed acute penetrating ulcers of the jejunum. The other 3 cases have been continued on medical therapy. One of these patients has had eight

readmissions to the hospital for intractable pain, which was complicated on two occasions by bleeding. A second patient has had three hemorrhages in the past two years.

Discussion

It appears from this study that when bleeding occurs following a gastroenterostomy or subtotal gastrectomy for a duodenal ulcer it is usually due to an ulceration in the jejunum and only occasionally to such a lesion in the stomach or duodenum. In these cases free HCl is invariably present in appreciable amounts. When bleeding is painless, the ulceration as a rule is superficial. When the bleeding is associated with pain, the ulceration is generally found to be deep and actively penetrating. It has been seen that the degree of bleeding is no indication of the depth of the ulcer, for patients with superficial lesions bled as severely as those with deep ones. No patient in this series died from bleeding. It is recognized, however, that there is always the possibility of a fatal termination with gross hemorrhage from any peptic ulcer. The first death in this clinic from a late bleeding following gastroenterostomy for a duodenal ulcer occurred during the past year. A postmortem examination revealed an erosion in the jejunum as the source of the hemorrhage. Because of the rarity of a fatal complication and the fact that surgery in secondary ulcers following gastroenterostomy and subtotal gastrectomy is so hazardous, it is strongly felt that the bleeding in this group should always be treated conservatively.

In this study, the majority of patients who bled following gastroenterostomy and subtotal gastrectomy also bled before operation. While this may suggest the possibility of a bleeding diathesis, there has been no evidence to prove such a contention. It seems far more likely that the hemorrhages that recur in the same individual before and after a gastroenterostomy or a subtotal gastrectomy for duodenal ulcer are merely the results of the recurring ulcerations. For the same reasons we feel that the frequency of bleeding is purely fortuitous and is dependent upon the factors that determine the remission or recrudescence of peptic ulcer.

In this discussion no distinction is made between "erosions" and the "chronic peptic ulcer." However, these lesions are different pathologically. Erosions are frequently ascribed to "gastritis," "duodenitis," or "jejunitis." They are a manifestation of peptic ulcer when they occur in an individual with a known

ulcer diathesis and in the presence of free HCl. This is a well-recognized point of view. Opinions differ only as to whether gastritis is a precursor or an associated effect of peptic ulceration.

Patients who present bleeding without pain as a rule respond to conservative medical therapy because, as has been demonstrated, the ulcerations are superficial and heal readily. This has been noted in the painless bleeding attributed to erosions or superficial ulcerations of the duodenum. It has been seen in the gastrojejunal ulcerations that follow gastroenterostomy and the Billroth II type of subtotal gastrectomy. The conservative therapy employed may consist of any of the approved medical methods (Meulengracht's diet, absolute gastric rest, sedation) with parental administration of saline glucose and blood. Surgery that entails an appreciable mortality is to be avoided.

Bleeding accompanied by pain presents a different problem. It portends a penetration of an ulcer which, in most instances either because of intractability to medical treatment or because of mechanical complications, requires surgical interference. Operation should be done during a quiescent stage. The best end results in the treatment of gastrojejunal ulceration associated with pain and hemorrhage following gastroenterostomy are obtained by resection of the jejunal ulceration and radical subtotal gastrectomy.

However, the group of patients which presents bleeding with pain following subtotal gastrectomy is in a different category, for—regardless of the extent of gastric resection, the adequacy of alkaline intestinal regurgitation, and the rapidity of stomach emptying—the gastric analysis still shows free HCl.

Free acidity, combined with an underlying ulcer diathesis, produces an ulceration that appears to be almost malignant in its tendency to recur. Conservative medical therapy, while it is temporary in its effect and at times futile, still offers more than any further radical surgery that is almost always fatal.

Conclusion

Bleeding, manifested by melena or hematemesis with or without pain, occurs as a sequelae of gastroenterostomy and subtotal gastrectomy. Bleeding without pain following either type of operation is usually due to a superficial ulceration and, as a rule, responds to conservative therapy. Bleeding with pain is invariably due to active penetrating ulcera-

tion This syndrome following gastroenterostomy is amenable to surgical excision of the area of ulceration and to subtotal gastrectomy Cases of bleeding with pain following radical subtotal gastrectomy do not respond, as a rule, to medical measures, and at present

the surgical approach is limited by a prohibitive mortality

THE OPHTHALMIC QUACKS OF LONDON

An ophthalmic surgeon, Mr E W Brewerton, has contributed to *St Bartholomew's Hospital Journal* an account of the ophthalmic quacks who have flourished in London during the last twenty years These quacks may be classified as (1) those who say that every chronic eye condition can be cured by glasses, (2) those who claim the same for other means, usually electricity, (3) those who claim to relieve every error of refraction by exercises and say that all glasses are unnecessary, (4) the osteopaths, who will guarantee a cure for everything from prunus ani to detached retina by replacing a displaced vertebra, and (5) the psychoanalysts The first class orders patients suffering from errors of refraction, cataract, optic atrophy, or macular degeneration to read for a certain number of hours daily with strong magnifying glasses A man named Fournier, who was backed by a well-known admiral, was the originator of this method He claimed that his glasses were of secret manufacture He flourished for many years until the business was taken over by Wright, who died after a few years of lucrative practice, to be followed by his brother The present proprietor of the business displays a printed notice that he cured a certain cabinet minister when London ophthalmologists failed

The quacks who claim to cure by electricity flourish on the many who have a horror of operation on the eye A man with advancing cataract was told to attend three times a week at a fee of \$30 One pole of a galvanic battery was applied to the neck and the other was passed round the orbit At every visit the nurse told him he was better, but as his vision deteriorated the chair was put nearer to the type to make him believe that he was improving At least six rooms used in the house were always full, the proprietor must have been making \$250,000 a year The patient was told that his was a difficult case and that another course was necessary This he declined

Those who treat presbyopia and errors of refraction by exercise and say that all glasses are unnecessary deny that accommodation depends on the ciliary muscle and attribute it to the extrinsic muscles of the globe Their leader says that the more the eyes are used the stronger they get and that light, especially sunlight, is a cure for all kinds of defective sight Mr Brewerton mentions the case of a boy with 4 diopters of myopia who was promised a cure After twelve months' treatment by exercises he could not see 6/60 and his error is now 4 5 diopters —J A.M.A. *London letter*

PETER IRVING, M D, Secretary

VASOMOTOR RHINITIS

A Clinical Study of 45 Cases

HENRY I. SHAHON, M.D., F.A.C.P., Medical Officer, Veterans Administration, Albuquerque, New Mexico

FORTY-FIVE cases of vasomotor rhinitis were selected from the asthma and hay fever adults' clinic of the New York Post-Graduate Medical School and Hospital with the following points in mind (1) age of the patient, (2) age of the onset of symptoms, (3) race, (4) nationality, (5) sex, (6) occupation, (7) presence or absence of allergy in the family history, (8) number of years the patient was under treatment, (9) chief complaint, (10) presence or absence of associated allergic conditions, (11) presence or absence of associated nonallergic conditions, (12) knowledge of the presence of any food aversions, (13) knowledge of the presence of any drugs causing or aggravating symptoms, (14) knowledge of the presence of any contacts proved clinically to have caused symptoms with positive skin tests before treatment, (15) the findings of the direct nose and throat examination, (16) determination of sinus infection by—(a) history of frequent colds, (b) transillumination, (c) x-ray examination, (d) exploratory puncture, (17) positive skin tests, (18) specific treatment, (19) nonspecific treatment, (20) amount of improvement

(1) *Age of the Patient*—The ages ranged from 15 to 45 years. There were 8 patients in the second decade of life, 13 in the third, 8 in the fourth, 12 in the fifth, and 4 in the sixth

(2) *Age of the Onset of Symptoms*—The age of onset of symptoms ranged from 8 to 50 years—that is, the youngest patient developed vasomotor rhinitis at 8 and the oldest at 50 years. There were 1 in the first decade of life, 12 in the second decade, 15 in the third, 7 in the fourth, and 10 in the fifth

(3) *Race*—All patients under study belonged to the white race, except 1 who was a mixed breed

(4) *Nationality*—Thirty-one were Americans—that is, born in the United States but still of recent foreign extraction—4 Russians, 1 Rumanian, 3 Italians, 1 Irishman, and 1 Puerto-Rican

(5) *Sex*—There were 12 men and 33 women

(6) *Occupation*—There were 23 housewives, 1 attorney, 1 clerk, 1 bookkeeper, 6 students, 2 salesmen, 2 nurses, 3 tailors, 1 upholsterer, 1 musician, and 4 unemployed

(7) *Presence or Absence of Allergy in the Family History*—Twenty-seven patients or 60 per cent gave a positive family history of allergy (asthma, hay fever) in one or more antecedents. Eighteen patients or 40 per cent gave a negative family history of allergy in the antecedents. This corresponds very well with the work of Cooke and Spain¹ on the inheritance factor in asthma and hay fever.

(8) *Number of Years the Patient Was Under Treatment*—Of the 45 cases studied, 1 had received seven years of treatment at the clinic, 3, six years, 1, five years, 4, four years, 1, three years, 6, two to three years, 23, one to two years, and 6, less than one year

(9) *Chief Complaint*—The chief complaint of all the 45 cases was vasomotor rhinitis—that is, one or more of the following symptoms (a) nasal congestion or occlusion of varying degrees, (b) fullness and discomfort in the paranasal sinuses, (c) watery or mucoid discharge from the nose, (d) sneezing, (e) itching in the nose, throat, palate, ears, or skin of the face, (f) hoarseness from congestion or edema of the larynx, (g) soreness and congestion of the larynx, (h) impaired hearing, (i) hawking or clearing of the nasopharynx and throat, (j) lacrimation, itching, burning, or redness of the conjunctiva

In some, these symptoms were revealed in paroxysms, in others, they were more pronounced from arising until midmorning or noon or on retiring

(10) *Presence or Absence of Associated Allergic Conditions*—The associated allergic conditions were (a) bronchial asthma, 4 cases, (b) hay fever, 19 cases, but only 12 patients knew it beforehand, (c) neurodermatitis, 1 case, (d) urticaria, 7 cases, (e) migraine, 1 case, but not severe

(11) *Presence or Absence of Associated Non-allergic Complaints*—The associated nonallergic conditions were (a) emphysema, 1 case, (b) cholecystitis, 1 case, (c) pulmonary hemorrhage, 1 case, (d) endocervicitis and menopause, 1 case

From the Department of Medicine, Division of Applied Immunology, New York Post-Graduate Medical School and Hospital, Columbia University, New York City

(12) *Knowledge of the Presence of Any Food Aversions*—Not one patient knew definitely that foods could aggravate or cause the vasomotor rhinitis symptoms. There were, nevertheless, a few who complained of vague, mild, gastrointestinal disturbances accompanied by slight headache.

(13) *Knowledge of the Presence of Any Drugs Causing or Aggravating Symptoms*—Likewise, with the drugs, not one patient knew that their ingestion or topical application would increase or cause any symptoms of vasomotor rhinitis.

(14) *Knowledge of the Presence of Any Contacts Proved Clinically to Have Produced Symptoms with Positive Skin Tests Before Treatment*—Only 1 patient knew definitely that each time he petted a cat he would develop symptoms of vasomotor rhinitis and slight dyspnea.

(15) *The Findings of the Nose and Throat Examination*—The direct nose and throat examination revealed 41 cases of vasomotor rhinitis. The examination of these patients was performed by a competent rhinologist attached to the asthma and hay fever clinic. Practically all these cases showed varying degrees of these findings: blanched, swollen mucous membrane, boggy, blanched inferior and middle turbinates, and a thin discharge or rhinitis.

(16) *Determination of Sinus Infection by*
(a) history of frequent colds—18 patients gave a history of having frequent colds.
(b) Transillumination—transillumination disclosed 11 cases of sinusitis, of these, 7 were definitely confirmed by positive x-ray findings and subsequent exploratory punctures.
(c) X-ray examination—x-ray examination seemed indicated by the rhinologist in only 7 cases. These were the findings: membranous infiltration of right antrum and both ethmoids, 4 cases, slight membranous infiltration of right antrum alone, 1 case, membranous infiltration of left antrum alone, 1 case, membranous infiltration of both antrums and ethmoids, 1 case.
(d) Exploratory antrum puncture—exploratory puncture revealed negative findings in all but 5 cases. Autogenous vaccine from the antrum washings was prepared in 2 cases only.

(17) *Positive Skin Tests*—All patients were thoroughly tested by the intracutaneous method with all the inhalants and foods. The reactions were recorded as slight, moderate, or marked depending upon the size and outline of the wheal and the amount of erythema, with or without itching of the site.

Only the marked reactions are recorded in this paper. There were, of course, some slight and moderate reactions also. Thirty-eight patients reacted to house dust, 1, to tree pollens (this same patient was sensitive to timothy and plantain), 10, to timothy and plantain, 14, to ragweed (5 patients were from the timothy- and plantain-sensitive group), 17, to feathers (chicken, goose, and duck), 7, to orris root, 3, to dog, 2, to cat, 2, to silk, 1, to horse epithelium, 1, to rabbit, 1, to kapok, 1, to cottonseed, 1, to trichophytin, and 1 each, to egg, chocolate, orange, pork, lamb, beef, tomato, tea, white potato, green peas, spinach, banana, and cantaloupe.

(18) *Specific Treatment*—Before undertaking any form of specific treatment each case was carefully summarized, and the following points were again taken into consideration: (a) careful review of the family and past histories, (b) the question of previous nasal operations, (c) the environmental factor, (d) the seasonal influence, (e) food idiosyncrasies, (f) the question of retesting where necessary, even the employment of the indirect method of testing of Prausnitz and Küstner.²

In every case the hyposensitization, desensitization, or immunization method was started. Instructions were given regarding elimination of the offending agents from their immediate environment and the diet.

The most important extracts used for immunization were house dust, feathers, and orris root. At times, rabbit, cat, dog, and silk were also used.

Each patient received weekly injections of the extracts to which he was found sensitive. At first, the marked reactions were taken into consideration. Later, the moderate, and at times slight, readings were also considered in the order of their importance.

The patients who reacted to pollens and knew definitely that they felt worse during the seasons of pollination were treated as the case indicated, they received weekly injections of the respective pollens.

There were 19 cases of pollen sensitivity in all. One patient was sensitive to timothy, plantain, and three pollens, 4, to timothy and plantain, 5, to timothy, plantain, and ragweed, the last 9 patients, to ragweed (giant or tall and dwarf or common ragweed). Of all these 19 pollen-sensitive cases, only 12 patients knew that they had had hay fever before being tested. The remaining 7 patients, even though they reacted to pollens, were not treated, since they did not know

definitely whether or not they felt worse during the spring, summer, or fall. However, they were instructed to observe any increase of severity of symptoms of vasomotor rhinitis during these pollinating seasons.

There were 13 clear-cut cases of vasomotor rhinitis—that is, those without any other associated allergic conditions. They received subcutaneous injections of the offending allergens in gradually increased doses until sufficient tolerance was obtained. The maximum doses given to these patients ranged as follows: $\frac{3}{10}$ cc of concentrated house dust, 5,000 protein nitrogen units of feathers extract, 5,000 to 10,000 protein nitrogen units of ornithin root extract. For those who received injections of other animal epitheliums—like dog, cat, and rabbit—the maximum dose for each was approximately 1,000 protein nitrogen units. (One Cooke and Stull protein nitrogen unit equals 0.00001 mg of protein nitrogen of pollen. In the case of inhalants and foods, each substance has its specific proportion between the total and the protein nitrogen.)

There were exceptions, of course, each patient was studied individually. The above method of immunization or hyposensitization was selected when elimination or avoidance of the offending agent was impossible or impractical.

The problem of food sensitization was studied by the combined method of trial and elimination. All the foods and drugs that the patient knew would cause or increase his symptoms of vasomotor rhinitis were eliminated from his diet. As previously stated, this condition was not known to any of the patients under study.

The next procedure was the elimination of all foods that gave marked positive skin tests from the patient's diet. Each patient was also asked to keep a dietary diary of all foods eaten and to note the time and place of the development of any symptoms of vasomotor rhinitis or its allied conditions. If he was symptom-free on this kind of diet for a period of a week, he was told to introduce another of the foods giving a marked positive skin test in his diet. If the food this time caused any symptoms of vasomotor rhinitis, within a half hour or longer, it was removed from the diet. This food was again tried at some later period to ascertain its true allergenic nature.

If the patient's condition remained unimproved after removing from his diet the foods that reacted markedly, then the same

procedure was undertaken with the moderate and the slight reactions. In each case, foods giving positive skin tests and those suspected from a study of the food diary were excluded from the diet. When the patient became symptom-free, feeding of the suspected foods was again instituted. If symptoms followed, this observation was again checked and rechecked by repeated trial and elimination.

All other available methods—like the trial diet method of Eyermann,³ the trial diet of Vaughan,⁴ and the elimination diets of Rowe⁵—may be tried. The immunization or hyposensitization method alone is not sufficient, the combined method of immunization and food elimination as described is the desired one.

The general consensus is that foods do play a certain role in the causation of vasomotor rhinitis and other allied conditions, they should not be overlooked. Because a food gave a positive reaction on skin testing, it does not mean that clinically it is also positive. It is best that the tests and clinical symptoms agree, but this is not always the case. If the common offenders—such as milk, eggs, wheat, chocolate, nuts, pork, mustard, fish, shellfish, strawberries, and oranges—are removed from the diet and if also all the foods the patient dislikes, those he likes so much that he overeats, and those he fears and suspects of causing symptoms are omitted from his dietetic diary, the problem of food sensitization is much simplified.

There is no known hyposensitization method for foods which has proved to be of any great value. However, some believe that by giving orally small amounts of the offending foods and gradually increasing their amounts, the tolerance to these foods might be raised. This method so far has not proved to be effective.

(18) *Nonspecific Treatment*—The use of glandular extracts should be considered in these cases of vasomotor rhinitis. In the cases under study, one patient was definitely worse at the menopause. The administration of estrogenic substance parenterally aided her improvement.

Vitamin therapy was also tried in only a small number of patients with slight appreciable results. Some men like Rosenberg⁶ and others have shown that vitamins do play an important role in the allergic eczemas, asthma, and hay fever.

The medicinal use of ephedrine and epinephrine was tried, at times in the form of spray or local application and at times in the

form of capsules, from $\frac{3}{8}$ to $\frac{1}{4}$ grain each, twice or three times daily. Injections of epinephrine or adrenalin, 1 to 1,000, were used only when the symptoms were severe or during a constitutional reaction. Not many patients required injections of adrenalin during their treatment.

The infected cases—namely, those with sinus infection—were carefully examined by the rhinologist, and the necessary treatment was instituted. Some patients required suction and packing of the nose alone, while others required puncture of the antrums with subsequent washings with sterile isotonic solutions. These patients showed varying degrees of improvement.

(20) *Amount of Improvement*—The amount of improvement that the patients received is as follows:

Twenty-one patients received a great deal of relief—that is, they showed definite improvement. The majority were sensitive to house dust, feathers, orris, and pollens on direct testing. They were also sensitive, to a lesser degree, to foods and were free from any sinus infection. The therapeutic measures employed were those of immunization or hyposensitization and the combined method of trial and elimination of the allergenic foods.

Seven patients showed moderate improvement—that is, the paroxysms of rhinitis and sneezing became less and less following the treatment. Of these 7 cases, 1 patient had an infection of the antrum and improved when the rhinologic treatment of suction and packing was instituted.

Five patients showed a slight degree of improvement. Every one of these had an infection of the sinuses—namely, the antrums or ethmoids or both. There were no cases where radical operation, like the Caldwell-Luc, was necessary.

Six other cases fared poorly. Of these, 2 had sinus infection and were being treated, 1 was irregular in attendance, another discontinued the treatment too soon, the other 2 had other sensitivities that were overlooked.

The last 6 cases did not receive sufficient treatment, either specific or nonspecific, and were not ready for an opinion as to the degree of improvement received.

What is the proper management of the other group of allergic rhinitis or vasomotor rhinitis patients who present positive antecedent allergic histories, positive clinical symptoms and signs, but no positive skin tests?

As in the group with positive skin tests, all the ingestants, inhalants, and contactants that are known to cause any symptoms are first eliminated from the patient's immediate environment and diet. Then, a careful study of the nasal passages, roentgen-ray studies of the sinuses, cytologic and bacteriologic studies of the secretions, and possible antroscopic studies of the antrums, together with a careful history, are undertaken. If these patients present any obstruction in the nasal passages—like organized polypi, markedly deviated septums, or hypertrophied turbinates—they are removed or corrected. This conservative attitude should be taken after the allergy has been studied and brought under partial or complete control.

In individuals in whom allergic therapy fails to control symptoms, the repeated removal of polypi, washings of antrums, or local nasal therapy is justified provided some relief is given them.

The other methods that are still being used by several rhinologists are cauterization and ionization. Some use concentrated carbolic acid to paint the surface of the mucous membrane of the nose, others use other escharotics—like trichloroacetic acid—and the injection of absolute alcohol in the subcutaneous tissues. Their use is unscientific, and in Hansel's⁷ and other men's opinions they are apt to yield serious damage to the nasal mucosa. According to Alexander,⁸ this method of cauterization is usually unsuccessful in patients with definite allergies. Hansel⁹ again recently stated that good results might be expected from ionization—not cauterization—in those vasomotor rhinitis patients with negative skin tests and warned against the procedure in the presence of acute infection of the nose and sinuses. The relief obtained from either method is usually temporary, and as soon as the mucous membrane returns to its original state the symptoms reappear. Other rhinologists have recommended many other local therapeutic measures. They are warranted only when such nasal symptoms are not controlled by the adequate allergic diagnoses and therapy carried out over a prolonged period by an experienced allergist.

The use of vaccines, as in bronchial asthma, should not be overlooked. The important point, however, is to recognize all allergies other than bacterial before vaccine therapy based on sensitization to bacteria is instituted. Either stock or autogenous preparations may be employed. Skin tests with vaccine are of no diagnostic value so far as the etiology of

focus of infection in vasomotor rhinitis is concerned, but according to Thomas and his coworkers¹⁰ they are of definite assistance in selecting a suitable vaccine for the treatment of each patient

At the clinic, stock vaccine is mostly used. It contains these microorganisms: *Micrococcus catarrhals*, *Friedländer's bacillus*, *pneumococcus* (types I, II, III, and IV), *streptococcus* (hemolyticus and viridans), *staphylococcus* (albus and aureus), and *Bacillus influenzae*. At times, autogenous vaccine is also used. Favorable results are obtained as frequently with stock preparations as with autogenous ones. In any given case, however, one form may succeed where the other has failed. Dosage in vaccine therapy usually starts with small amounts, ranging from 50,000,000 organisms as the initial dose and gradually increasing to a maximum of 1,000,000,000 to 3,000,000,000. A slight delayed local reaction at the site of the subcutaneous injection is desirable, but not essential, for favorable results.¹¹ The doses are usually given at weekly intervals.

Physical allergy as a possible cause in a small group of vasomotor rhinitis is also to be considered. Chilling, change in temperature, weather, location and elevation, humidity and wind seem to exert a special influence on these patients for good or evil. They possibly act as secondary factors in the same manner as vapors, certain odors, and perfumes do—by stimulating the already existing sensitization in the cells of the tissue of the upper part of the respiratory tract.

Menstruation, pregnancy, and dysfunction of the thyroid and other gonads have been reported to be of secondary influence in some of the vasomotor rhinitis cases also. It is, however, possible that fluctuations in the female sex hormone may change the allergic balance. Some are of the opinion that the adrenals play a greater role in allergy. It is a well-known fact that epinephrine relieves and controls any allergic manifestations, even though transitory. It is also a fact that low blood pressure often exists in a large percentage of allergic patients. All this suggests a deficiency in adrenal activity. No striking results have so far been obtained from the ingestion or injection of adrenal substance.

Nervousness, excitement, and emotion as secondary factors have been mentioned to exaggerate any allergic state. The general trend is to condemn them when no other allergic causes have been found.

Conclusions

A series of 45 cases were taken at random from the allergy clinic for adults of the New York Post-Graduate Medical School and Hospital for purpose of study with twenty points in mind. Each point has been thoroughly discussed in this paper under separate headings, and as a result the following recommendations have been drawn.

1 To remove all the positive inhalants and foods, particularly those that are known to cause symptoms, from the patient's environment and diet.

2 To employ the immunization or hypsensitization method when necessary. To remember, of course, the long period of time necessary for successful immunization, from six months to a year or longer.

3 To make a careful survey of the patient's diet and eliminate the foods with positive skin tests from the diet, but to use good judgment and discretion in their elimination. If positive symptoms exist following their ingestion, to remove them immediately. To take care also not to endanger the patient's health by too much elimination, for more harm can be done by starvation.

4 To remove, if present, all foci of infection—like sinusitis, infected teeth, and others.

5 To prescribe the necessary medicinal treatment even though it is palliative at first. The useful drugs are ephedrine and epinephrine or adrenalin. Be on the lookout for ephedrine sensitivity. Also, to use vitamins when indicated and, likewise, glandular extracts in the suspected cases of hypogonadism, particularly at or near the menopause. Calcium and potassium are as yet of doubtful value.

6 A change in locality is sometimes advisable in some cases. It is best to tell the patient to go to a dry and warm climate. High altitudes seem to agree with the allergic patient.

7 The following recommendations are to be given the vasomotor rhinitis sufferers: (a) not to live in damp places, like basements or cellars, (b) not to sleep on feather pillows or mattresses, (c) not to have any pets (dog, cat, etc.) at home, (d) not to use face powder or other cosmetics containing orris root, (e) not to be engaged in dusty occupations, like tailoring, mulling, and sweeping, (f) not to use perfumes of any kind on their clothes or hair and lotions for setting the hair, (g) not to undertake long automobile rides, particu-

larly in an open car, and not to remain too long in crowded places

8 Finally, not to lose sight of the fact that we are dealing with a constitutional illness and not of vasomotor rhinitis alone. Hence, steps are to be taken to correct any abnormalities and to treat any other local or systemic disturbances that may be impairing the patient's health. In this manner one assists in restoring these poor unfortunates to as nearly a normal state as possible.

NEW MOTOR VEHICLE SAFETY-RESPONSIBILITY LAW

A special bulletin from Joseph S. Lawrence, M.D., Legislative Bureau of the State Society, dated November 13, 1941, reads as follows:

"Are you familiar with the provisions of this new law which will go into effect January 1, 1942? If you are not, may I suggest that the next time you stop at a filling station for oil or gasoline, you ask for a pamphlet entitled *You and the New Motor Vehicle Safety-Responsibility Law*, which was published by the State Department of Taxation and Finance.

"The new law does not compel owners of motor vehicles to be insured—that is, it is not a compulsory insurance measure—but it does oblige owners to guarantee to maintain proof of future financial responsibility.

"The principal provision in which hospitals and physicians will be interested is that any owner of an automobile is liable for payment in full of all expenses resulting from personal injury to anyone involved in an accident where his car is at fault. Therefore, hereafter the hospital or physicians rendering services to persons injured in automobile accidents should not suffer the financial losses that they have suffered in the past.

"If an operator or owner involved in an accident was not insured or bonded, he must meet two specific requirements of the act if he wishes to retain driving and registration privileges: (1) immediately put up sufficient security to satisfy any judgment that might result from the accident and (2) immediately furnish proof of financial responsibility for the future.

"Bills should be rendered promptly to the patient or notice served the patient that the bill will be rendered in due time. If the responsibility for the accident is not his, he will pass the bill to the responsible party. Since the Commissioner of Motor Vehicles is empowered to suspend, within from ten to forty-five days after receiving a report of the accident that resulted in bodily injury, the driving license of operators and all registration certificates and plates of owners of motor vehicles in any manner

involved in the accident, unless they pay the bills or assume responsibility for their payment, it is obvious that the responsible parties will attempt to effect prompt settlement.

"This law should accomplish everything that we had hoped to achieve through our lien bill, so far as automobile accidents are concerned.

"The Department of Motor Vehicles has offered to detail one of its staff to discuss and explain the law to any medical society that might make a request. There is much more to the law than the features I have mentioned above, for instance, a man cannot escape his responsibility by going into bankruptcy. If he loses the license for operating one car, automatically he loses the licenses for any other cars that he may have in his possession. Until the judgment is satisfied, a car from which a license has been suspended or revoked cannot be licensed by any other person. This means that 'if a person sells his car or transfers it to another member of his family or anyone else after losing his registration privileges for any of the reasons above named, the new owner will not be able to obtain registration plates in this state for the car.' The law applies to drivers from other states while they are operating cars in this state.

"If a person who has neither license nor registration becomes subject to the law as the result of an accident, he will be barred from driving or registering a car in this state. Failure to report an accident constitutes a misdemeanor and is ground for suspension of the driver's license or registration, or both, of the person failing to make a required report.

"The new law does not apply to any judgments or civil actions arising out of accidents occurring before January 1, 1942.

"Since this description and explanation are so limited, if any questions should arise, I shall be glad to make an effort to answer them if you give me the opportunity."

INCREASE IN HEIGHT AND WEIGHT AMONG THE UNDERPRIVILEGED

SAMUEL C. KARLAN, M.D., Dannemora, New York

A NUMBER of studies have been made which indicate that the general height and weight of the race is increasing. Mosher¹ noted that the height of Stanford University women students had increased 25 cm in thirty years. Gray² observed that American boys of American-born parents were more than 2 inches taller than the same type fifty years earlier. A study^{3,4} made at Harvard University which compared the heights of 1,166 fathers and 1,461 sons indicated that the mean height of the fathers was 68.6 inches while that of the sons was 70 inches. Chenoweth⁵ compared the heights and weights of college freshmen who had been admitted to the University of Cincinnati from 1916 to 1936 and noted that the men increased in height from 67.45 inches to 69.23 inches and in weight from 132.05 pounds to 141.79 pounds. He therefore concluded that mankind was steadily growing taller and attributed it to the higher standards of living, higher degree of health intelligence, decrease in communicable disease, and better nutrition.

Many investigations⁶ show that economic status and social position influence growth a great deal. Chenoweth also observed that the mean height of the students at the University of Cincinnati was slightly lower than that at Harvard and attributed it to the greater wealth and social position of the latter group. However, the studies mentioned above dealt almost entirely with the middle and upper classes from which the vast majority of college students are drawn. We therefore thought that it would be of scientific value to determine how the heights and weights varied in the lower classes of society. We could not find a more representative sample of the poorer elements and those with the lowest social position than the inmates of a state prison. Moreover, this material lent itself to investigations of this nature since we had reliable data as to height and weight in the records of the inmates.

A study was therefore made of the heights and weights of all the admissions to the Clinton State Prison from January 1, 1910, to October 1, 1940. These were all sorted with

respect to their year of birth so as to create age groups that passed through their period of growth at approximately the same time. The dates of birth varied from 1840 to 1923 but, since there were too few cases in some of these years, only the years 1871 to 1920 were used. We thus found 10,923 cases suitable for our investigation. The mean heights were then calculated for each five-year period. Because of the influence of age on weight, the cases for each year of birth were further divided into three age groups: 17 to 29 years, 30 to 39 years, and over 40 years according to their age on admission to prison. The mean weights were then calculated for each ten-year period. The average deviations and probable errors were derived for all the means. The results are given in Tables 1 and 2.

There was a difference in height of 1.4 inches between those born in 1871 to 1875 and those born in 1916 to 1920. Since this is thirteen times the probable error (a difference of twice the probable error being sufficient to make a result statistically significant), we must conclude that even the underprivileged are increasing in height. However, we must also note that the gain in height for a period of fifty years was equal only to the gain achieved by the Cincinnati students in twenty years and by the Harvard students in one generation. Moreover, while the Cincinnati students were about 0.7 to 1.2 inches shorter than the wealthier Harvard boys, the Clinton Prison inmates were about 1.5 inches shorter than the Cincinnati freshmen. We may therefore say that our rising standard of living, improved health conditions, and better nutrition have affected the poor and the underprivileged, as well as the other groups of society, although to a lesser extent.

A gain in weight was also found between the inmates born in 1871 to 1880 and those born in later years. The group that was 17 to 29 years of age showed an increase of 2.7 pounds (about six times the probable error) in thirty years. The group that was 30 to 39 years of age had an increase of 5.2 pounds in thirty years (about eight times the probable error). The group over 40 years of age on admission to prison showed a difference of

From the Clinton State Prison, Dannemora. Dr. Karlan is at the Dannemora State Hospital.

TABLE 1—HEIGHTS OF INMATES 1871-1920

Year of Birth	Number of Cases	Mean Height in Inches	Probable Error, Inches
1871-1875	370	66 3	±0 12
1876-1880	582	66 6	±0 09
1881-1885	976	66 6	±0 07
1886-1890	1422	66 3	±0 06
1891-1895	1721	66 5	±0 05
1896-1900	1728	66 7	±0 05
1901-1905	1495	67 0	±0 05
1906-1910	1232	67 3	±0 06
1911-1915	1017	67 6	±0 07
1916-1920	374	67 7	±0 11

TABLE 2—WEIGHTS OF INMATES 1871-1920

Year of Birth	Number of Cases	Mean Weight in Pounds	Probable Error
(a) 17-29 Years of Age on Admission			
1881-1890	1017	144 6	±0 4
1891-1900	2137	145 2	±0 3
1901-1910	1972	147 4	±0 3
1911-1920	1391	147 3	±0 4
(b) 30-39 Years of Age on Admission			
1871-1880	447	144 7	±0 7
1881-1890	867	149 6	±0 6
1891-1900	958	151 4	±0 6
1901-1910	758	149 9	±0 6
(c) Over 40 Years of Age on Admission			
1871-1880	505	151 5	±0 8
1881-1890	514	154 2	±0 8
1891-1900	360	157 6	±0 9

61 pounds (about six times the probable error) All these results are statistically significant, although they are all appreciably lower than the difference of 9 7 pounds shown by the Cincinnati students Incidentally, it may be noted that among the poor, as well as among the wealthy, weight tends to increase with age, since the group over 40 years

old was 7 to 10 pounds heavier than the group 17 to 29 years of age

Summary

1 Prison inmates born in 1916 to 1920 were 1 4 inches taller than those born in 1871 to 1875 and 2 7 to 6 1 pounds heavier

2 Even the poorer and underprivileged groups of society are improving in height and weight However, this improvement is not so high as that shown among the wealthier and more comfortable groups

3 It is likely that the increase in height and weight is due to better nutrition, higher standards of living, and better health conditions, all of which have improved appreciably even among the lower strata of society

Acknowledgment is hereby made to Dr Blakely R. Webster, Dr Walter M. Martin, and Mr Joseph Kalish for their kind cooperation

Distribution of Sulfadiazine by the New York State Department of Health

Early in December the New York State Department of Health began the distribution of sulfadiazine throughout New York State, exclusive of New York City, to registered Doctors of Medicine and hospitals for the treatment of pneumococcal infections. As with sulfapyridine and sulfathiazole, state-issued sulfadiazine is intended only for those patients for whom purchase of this drug would be a hardship

The new drug, in packages of 60 tablets of 0 5 Gm each, may be obtained in the same manner and from the same laboratory supply stations as those furnishing the older compounds In compliance with the ruling of the State Board of Pharmacy, the actual signature of physicians requesting sulfonamide drugs is required, the printed request slip prepared by the Health Department is preferred, but a prescription or a letter signed by the physician will be acceptable

Sulfadiazine should not be used for the treatment of gonococcal infections, since experience indicates that it is not so effective in such cases as sulfathiazole or sulfapyridine Physicians are requested not to use state-supplied sulfadiazine for any infections other than pneumococcal, and they are urged to be careful not to leave in the home such tablets as may remain when cure has been effected, lest self-medication of other diseases and possible toxic reactions result

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

The patient was a 66-year-old white man admitted on October 2, 1941, complaining of shortness of breath and swelling of the feet and ankles of three weeks' duration. It was difficult to obtain an adequate history due to the fact that there was marked language difficulty. It was known, however, that he had been treated at Bellevue Hospital about one and one-half years ago for congestive failure. He apparently had no further difficulties until three weeks previous to admission when he suffered shortness of breath and swelling of both feet and ankles. This gradually progressed in severity until about three days prior to admission when he said he suffered sharp pain in the lower right portion of his chest. Past history was essentially negative except for that noted above.

The patient was described as an elderly, acutely ill, cyanotic, dyspneic, and orthopneic white man. He appeared to be in considerable distress and there were signs of marked dehydration noted. On admission the temperature was 101.6 F, pulse (radial), 72, apex, 120, respirations, 36, and blood pressure, 170/115. An examination of the skull was negative. The pupils were equal and regular and reacted to light and accommodation, the extraocular movements were normal. The conjunctivae were injected and suffused with a foul discharge. The ears were essentially negative as was the nose. On examination of the mouth four carious teeth were all that remained. The breath was fetid, the tongue was coated and dry. The pharyngeal mucous membranes were moderately injected. The neck veins were described as distended, the thyroid was not palpable, and there was no palpable adenopathy. The thoracic cage was emphysematous in type and respiratory lag was noted on the right. Cutaneous hyperesthesia was described over the right side of the chest posteriorly. There was flatness at the right base on percussion and the breath sounds were diminished, but fine inspiratory crackling rales were heard as high as the sixth dorsal vertebra. The percussion note at the left base was considered to be dull and a few moist

rales were heard over this area. The heart was enlarged to the anterior axillary line in the fifth intercostal space. The point of maximal impulse was considered forceful and a systolic thrill was palpable over this area. A harsh, high-pitched systolic murmur was audible over the mitral area. Because of the rapid fibrillation the examiner could not be sure as to the presence of any other murmurs. A pulse deficit of approximately 40 was noted. There was voluntary abdominal spasm and no masses were felt at the time of this examination. The liver and spleen were apparently not enlarged and a rectal examination revealed no gross abnormalities. The genitalia were those of a normal man. There was 4 plus pitting edema of both legs up to the knees, the reflexes were physiologic.

The patient was digitalized on admission and put on pneumonia routine with sulfapyridine. A sputum specimen was purulent but not bloody. The fibrillation persisted in spite of digitalization at the very rapid rate noted on admission. The signs in the right lower lobe persisted as noted. After a period of five days, dehydration was still present and fluids up to 2,000 cc per day were continued. The temperature remained at the approximate level of 101.0 F in spite of adequate level of 97 mg blood sulfonamide level. On the fourth day the drug was changed to sulfathiazole, and this was continued until the seventh day when sodium sulfapyridine was administered intravenously. This was continued until the time of the patient's death. A chest tap was performed and 100 cc of thin bloody fluid was removed from the right side of the chest. The patient went progressively downhill and expired on the eighth hospital day.

Laboratory Findings — The urinalysis showed a specific gravity of 1.023, a trace of albumin, and one red blood cell per high-power field. The white blood count was 18,740 with 88 per cent polymorphonuclears and 12 per cent lymphocytes, the red blood cell count was 5,120,000 with 100 per cent hemoglobin. A sputum examination revealed type IV pneumococcus. The blood Wassermann reaction was negative. The blood non-

protein nitrogen on admission was 43, on the sixth day, 48. The blood sugar was 133, the blood chlorides ranged from 429 to 460. The blood sulfonamide levels were 9.7 mg on two occasions. The temperature until two days before death remained at approximately 101.0 F, on the seventh day it spiked to 103 F and rose similarly on the day of death. An electrocardiogram taken on the second day revealed a ventricular rate of 100 in the presence of auricular fibrillation. There was moderate left axis deviation, QRS complex, 0.08 second. There was depression of the R-T segment in leads I and II and a diphasic T wave in leads III and IV, with a deep Q in lead III, frequent premature ventricular contractions were present. The picture was that of marked myocardial damage.

Discussion

DR EMANUEL APPELBAUM. This patient presented two groups of signs and symptoms which may or may not have been closely related—namely, cardiac and pulmonary. With regard to the cardiac status, there was definite evidence of congestive heart failure associated with cardiac hypertrophy, dilatation, and auricular fibrillation. It was difficult to decide whether this was a case of hypertension with superimposed arteriosclerotic heart disease or an instance of chronic mitral valvular disease. The murmur over the mitral area was certainly a harsh one. It must also be borne in mind that occasionally we see large failing hearts that cannot be clearly defined pathologically. Our impression was that this was an instance of hypertensive and arteriosclerotic heart disease with perhaps some damage to the mitral valve.

With regard to the pulmonary features it should be noted that a diagnosis of pneumonia due to *Pneumococcus* type IV was made shortly after admission. When the patient did not respond to sulfonamides in the usual manner, it became necessary to investigate the cause of the therapeutic failure. Several possibilities had to be considered. First, the causative pneumococcus might have become sulfonamide-fast. There is experimental evidence to indicate that if an organism becomes resistant to one sulfonamide it is also resistant to all sulfonamides. Clinically, however, that does not necessarily hold true. Also it was possible that the pneumonia was an atypical one, due to a bacterial agent other than the pneumococcus, or perhaps of virus etiology. It is generally stated that these atypical pneumonias do not respond to sulfon-

amides. In our experience, however, we have on occasion observed such cases make a satisfactory response to sulfonamides. The possibility that the patient had a pulmonary neoplasm had to be considered. We have all seen cases of bronchogenic carcinoma masquerade as pneumonia. The finding of bloody fluid from the right pleural cavity lent some support to this idea. Another possibility to be considered was pulmonary congestion with edema which, not infrequently, simulates pneumonia. Finally, we had to consider the possibility of pulmonary embolic infarctions that are frequently mistaken for an atypical or bronchopneumonia, especially when the infarcts are multiple—and, as a rule, they are multiple. This type of pulmonary infarction is caused by moderate-sized emboli occluding secondary or tertiary pulmonary artery branches. The small emboli, as a rule, present no symptoms, and a large embolus occluding the pulmonary artery or one of its major branches produces a severe clinical picture with dyspnea, cyanosis, substernal pain, collapse and, frequently, death.

It is important to bear in mind the relative frequency of pulmonary infarction in necropsy material both among cardiac and noncardiac patients, but particularly the former, the estimated incidence of this complication being 8 per cent. The majority of pulmonary infarcts complicates heart disease, such as coronary occlusion with myocardial infarction, hypertensive heart disease, rheumatic hearts usually with mitral stenosis and auricular fibrillation, subacute bacterial endocarditis, and a group of patients with cardiac enlargement with auricular fibrillation or flutter and no other abnormality. Most of the patients with pulmonary infarction are in congestive failure, which masks the infarct and makes the diagnosis difficult. Important clues to diagnosis may be marked dyspnea, pleuritic pain, persistent fever and tachycardia, recurrent hemoptysis, and jaundice. When a patient presents these symptoms, which are difficult to evaluate, the physician must think not only of pulmonary infection but also of pulmonary infarction.

It is also important to remember that pulmonary infarction in noncardiac patients may simulate heart disease by producing cor pulmonale or by producing rales and edema suggesting left ventricular failure. One must bear in mind, also, that pulmonary infarcts may be complicated by pneumonia or may be infected. The infection in such instances may lead to suppurative pneumonitis.

and may extend to the pleura, producing a suppurative pleuritis. Various streptococci or pneumococci are, as a rule, the organisms that cause such an infection, and they are derived from the respiratory tract, disseminating in a bronchogenic manner.

The source of pulmonary embolism may be a thrombus or vegetation from the heart, but the great preponderance of these emboli are derived from the veins of the pelvis and of the leg, most commonly the latter, especially in the region of the popliteal vein. In this connection I should like to mention the not infrequent cases of septic abortion with embolization to the lungs which masquerade as a pneumonia.

I have discussed this problem somewhat in detail because medical men frequently overlook this important complication of heart disease. In summary, we had a patient with marked congestive heart failure who also had pulmonary signs suggestive of pneumonia. The patient did not respond to sulfonamides. Various possibilities for the patient's failure to respond were suggested. Personally, I felt that the patient did not have pneumonia but had multiple pulmonary embolic infarcts.

DR ARNOLD KOFFLER: There are several features that I should like to discuss in this case, principally in relation to the pulmonary findings. The failure to respond to sulfonamides within a reasonable period of time—i.e., forty-eight hours—is presumptive evidence that the process was not pneumonic. Other features of this case were the presence of pain of three days' duration and a definite hyperesthesia of the chest wall. This combination is not at all uncommon in pulmonary infarction and the presence of bloody fluid strongly suggests this diagnosis. In addition, there is no doubt that this patient had hypertensive heart disease with auricular fibrillation. The possible foci of embolization are naturally two in number: first, mural thrombus and, second, a peripheral vein. Either one is a possibility.

DR MAX TRUBEK: The cardiac enlargement was due to hypertensive disease. I do not feel that this patient had pneumonia in spite of the finding of pneumococci in the sputum, but there was probably pulmonary edema with a hypostatic pneumonia. Statistics for many years have shown that the occurrence of pulmonary infarction is far more frequent than that of lobar pneumonia in patients in cardiac failure who present physical findings of consolidation.

DR MENNASCHE KALKSTEIN: Among the

remaining problems with which pneumonia study is concerned is that of the cases that do not respond to modern therapy. Chemotherapy, as we know, has been extremely effective in reducing the mortality from this disease. There remains, however, a not inconsiderable mortality, in addition to which some cases, in spite of recovery, do not respond in the fashion that is considered typical. We are now analyzing the accumulated cases of the pneumonia study conducted on the First, Second, and Fourth divisions of Bellevue Hospital during the past three years in an attempt to determine the causes of failure of modern therapy. The incomplete data suggests the following tabulation:

I Misdiagnosis

A Suppurative lung disease

- 1 Lung abscess
- 2 Bronchiectasis
- 3 Endobronchial obstruction with suppurative infection, including bronchogenic carcinoma

B Pulmonary tuberculosis including pleurisy with effusion

C Pulmonary infarction with or without infection

D Cardiac failure, acute localized pulmonary engorgement may closely resemble pneumonia, diffuse congestion may resemble bronchopneumonia

II Complications of Pneumonia

These include empyema, bacterial endocarditis, meningitis. Serum sickness may be a complication of treatment.

III Associated Conditions

- A. Renal insufficiency
- B. Pneumonia with congestive heart failure
- C. Diabetes mellitus
- D. Associated, unrelated infection

IV Resistant Organisms

A Rarely pneumococcus. Pneumococcus resistance to sulfonamides may be induced and thus strains remain pathogenic. Resistant strains develop in the course of pneumococcal endocarditis.

B "So-called virus" pneumonia. This usually does not respond to sulfonamides but runs a relatively benign course.

C Other pyogenic organisms, including Staphylococcus aureus hemolyticus and Bacillus Friedländer. The response of these organisms is variable.

D Streptococcus viridans has been shown to be capable of producing a severe pulmonary infection with

- little or no response to sulfonamides
- E Psittacosis, typhoid fever
- V Drug Fever
The disease may be cured by withdrawing the drug. Sulfathiazole produces drug fever most often. The possibility of this condition must not be overlooked, since its recognition is usually followed by cure, while serious results follow the continued administration of the drug.
- VI Low Blood Sulfonamide Level
This may be inadequate as a result of improper administration, vomiting, failure to absorb, rapid excretion, or high acetylation. It is, therefore, incumbent on the clinician to check these levels frequently.
- VII Indeterminate
Unfortunately, while this group is small, the cause of failure may not be apparent. Overwhelming infection with a highly virulent organism or lessened resistance with poor humoral response on the part of the host—especially with pregnancy, chronic alcoholism, or in late cases—accounts for some of these failures. It may be that in this group serum would be of added value.

Pneumonia adequately treated with chemotherapy before the fourth day of the disease in the absence of complicating factors should result in almost 100-per cent cure. Where the response is absent or slow there is probably an underlying cause.

Pathology

DR MAX-WILHELM JOHANNSEN. The body was that of a senile white man. There was no edema, clubbing, cyanosis, or jaundice. On opening the left pleural cavity, it was found to contain a moderate amount of clear straw colored fluid. The right pleural cavity contained a moderate amount of blood-tinged fluid which was divided into loculated areas by extensive thick, soft adhesions over the middle and lower lobes. The right lung was covered over the middle and lower lobes with a thick, soft, fibrinous yellow membrane that was easily stripped, revealing a lower lobe of a uniformly deep red color and increased density. The lung was noncrepitant and cut with greatly increased resistance. The cut surface was of smooth, deep red, homogeneous appearance. A similar area 4 cm in diameter was found at the lateral part of the right middle lobe. The right upper lobe showed decreased density, coarse creptitation, and decreased resistance to section, and on the cut surface the alveolar structure was unusually prominent. The left

lower lobe presented anteriorly, near the base, a roughened yellowish area overlying an elevated, firm, deep red area which, on section, resembled the tissue of the right lower lobe. The remainder of the left lower lobe was reddish, somewhat dense, of diminished creptitation, and of increased resistance on section, and reddish fluid could be expressed from the cut surface. The left upper lobe resembled the right upper. No areas of infiltration could be felt. On dissection of the right pulmonary artery the main branch leading to the right lower lobe was found to contain a large shiny blood clot, red-gray in color, which was loosely adherent to the vessel walls. A similar clot was found supplying the area of consolidation described in the right middle lobe, also, an adherent embolus was found in the artery supplying the consolidated area in the left lower lobe. The bronchi contained throughout a thick, brown, mucoid material that was difficult to scrape from the wall. The mucosa was everywhere thick, boggy, and injected.

The veins of the right upper and lower extremities were dissected, and organized and organizing thrombi were found in the median cubital and greater saphenous veins. These thrombi were prolonged beyond the area of excision. No gross evidence of canalization was seen.

The heart showed, except for hypertrophy and dilatation, no abnormal findings. The liver and spleen showed evidence of chronic passive congestion and there was some ascites.

The microscopic findings in this case substantiated the gross findings.

There is little to add to the obvious sequence of events in this case. We were fortunate enough to be able to find a well-organized thrombus in the greater saphenous vein of the right leg, which may very well have been the source from which embolization took place. The thrombi encountered in the antecubital vein were fresh and probably the result of intravenous treatment. The question of whether pulmonary infarction does occur in the absence of left-sided heart failure is still open to debate, and Dr Von Glahn, for instance, believes you can get infarction in a patient who has no evidence of pulmonary congestion.

Anatomic Diagnosis

Thrombosis of greater saphenous vein with emboli to pulmonary arteries.

Pulmonary infarction of right middle lobe,
 right lower lobe, left lower lobe
 Hemorrhagic pleural effusion, right
 Pleural effusion, left
 Fibrinous pleuritis, bilateral
 Emphysema, right upper lobe, left upper
 lobe
 Hypostatic congestion, left lower lobe
 Mucopurulent bronchitis
 Left ventricular hypertrophy and general-
 ized cardiac dilatation
 Chronic passive congestion of liver and
 spleen

Polyposis of sigmoid colon and bladder
 Ascites (slight)

DR. EMANUEL APPELBAUM It becomes obvious that not every case that is diagnosed as pneumonia is necessarily pneumonia. Ordinarily, the diagnosis of pneumonia presents no difficulties. But, there are occasions when the clinician is faced with a problem of differential diagnosis. This is particularly true when the patient fails to respond to sulfonamides. The possibilities discussed above must then be carefully considered and weighed before arriving at a definite conclusion.

"EDITORIAL STEW"

That editors are doing their bit on the subject of nutrition cannot be denied, for apparently no publication can get to press these days without its vitamins. Proof that the printed word is getting around is the recent question of a twelve-year-old "Doctor, when was Nutrition discovered?"*

It was, therefore, surprising—and puzzling—to flip through the September issue of *The Internist* without coming across a single mention of a calorie. But our anxious moment was due to haste alone, on second look we spotted the "stew" and found it so palatable that it is here with warmed over and served a second time.

"Editing and publishing a magazine is as easy as baking a cake. Take a couple of articles add a generous dose of features, and flavor with some illustrations. Arrange these in a suitable order and send to the printer. Allow to simmer for several days, after which serve hot."

"Cooking up *The Internist* is as easy as that—from your point of view. But ask a chef what goes into the making of a tasty dish. He'll tell you that the oven does the work of cooking, but the important part of the job comes before the stove is hot. He will stress the quality of the ingredients which go into his food, insisting only on the best if he wants a first-class job. He will guarantee to paralyze your palate if you shop according to his orders."

"Well, the kitchen of *The Internist* feels the same way. Do our shopping for us and tell us what you want. We'll cook up the meal."

* The question was asked of Dr. Burdige P. MacLean of Suffolk County.

OLD AGE

A symposium on old age was presented at The New York Academy of Medicine in 1928 and won an editorial in the New York *Times* of October 3 that year. The doctors decided that they could not prevent old age. Dr. George E. Vincent asked "Can an average man or woman of 65 or 80 hope to be fairly fit, reasonably alert, and of some use to the community, or is it only the exceptional person who may entertain that hope and reach that standard?" He also said "Doctors ought to be like the mechanics who take contracts to keep clocks going and on time rather than emergency men to be summoned when timepieces stop or are too fast or too slow." In the New York *Times* of October 3, 1928, it was said that Dr. Solomon Strouse had told the Academy that the kind or amount of food a person eats had little or nothing to do with his or her attainment of long life. Obviously, the doctor did not think people dug their graves with their teeth. He cited case histories to show that, while many abstemious persons reached a ripe old age, many others who restricted themselves in no way whatsoever also achieved that goal and enjoyed life to the end. He said doctors disagreed about diet anyway (he was then associate professor of medicine at the University of Chicago) and each individual must determine his own best ration. He had found comparatively few examples of gluttony that caused real harm and suggested that doctors would be wise to make as few changes in the diet of old folks well or sick, as possible. At the same meeting Dr. Russell L. Cecil remarked that "the best friends of the elderly arthritic are rest, heat, and aspirin"—*Medical Record*.

AMERICAN ORTHOPSYCHIATRIC ASSOCIATION TO MEET

The nineteenth annual meeting of the American Orthopsychiatric Association, an organization for the study and treatment of behavior and its disorders, will be held at the Hotel Statler, Detroit, on February 19, 20, and 21, 1942.

Copies of the preliminary program will be sent upon request to the chairman of the publicity committee, Dr. Helen P. Langer, Vassar College, Poughkeepsie, New York. A registration fee will be charged for nonmembers.

Abstracts of Proceedings
of the
NEW YORK PATHOLOGICAL SOCIETY

REGULAR MEETING, OCTOBER 30, 1941

DR JEAN OLIVER, *President*

DR JOHN M PEARCE, *Secretary*

The Pathology of Diabetes Mellitus Dr Shields Warren (*by invitation*), *Boston*

The pathology of diabetes mellitus is partly well understood and partly still confused. The lesions of the islands of Langerhans, particularly hyalinization and fibrosis, are adequate to explain some cases of the disease. Their experimental production in dogs and cats by anterior pituitary extract, apparently following the occurrence of hydropic degeneration of the insular cells, suggests the reality of the assumed relationship between the pituitary gland and the pancreas. Yet, the mechanism of production of hyalinization of the islands is as yet unknown. The occurrence of amyloid and para-amyloid reactions may be significant. Thus far, the significance of rather striking hyaline deposition in some functioning adenomas and carcinomas of the islands has not been determined.

In certain cases we have no morphologic evidence of abnormality in either pancreas or pituitary, and yet the type of disease shown by such patients in life is not distinctive.

Owing to the high diffusibility of sugar in the tissues, glycogen is our only help in the morphologic study of carbohydrate metabolism. Its characteristic storage and depletion in the diabetic patient have long been known, but even now we have no answer as to why the liver cell nuclei in the diabetic, and sometimes in the nondiabetic, patient become distended with glycogen.

Much interest has been aroused recently in the renal changes reported by Kimmelstiel and recently clearly presented by Allen. The renal deposition of hyaline material, while not specific to the diabetic process, is far more common in diabetic patients. Its occurrence is not restricted to cases of diabetes with edema. In my own series it has not been so frequent as in Allen's series, occurring in under 20 per cent of those over 40 years of age. The hyaline may be related to

that seen in the islands of Langerhans. When present, the lesion may be regarded as presumptive evidence of the existence of diabetes.

The chief problem of the diabetic patient is still arteriosclerosis, and the vessels of the leg and heart are still the most vulnerable. The lesion is typically atheromatous in type, not distinctive, but its age incidence and distribution are fairly characteristic for the diabetic patient.

Discussion

DR ARTHUR C ALLEN I want to state at the outset in all genuineness that there are many pathologists here who are more adequately equipped than I to discuss a paper on the pathology of diabetes or any other of a variety of papers which Dr Warren might have chosen to present before this Society. But this much I am sure of: he has rendered a real service in his compilation and evaluation in the past few years of the facts of the pathology of a disease whose morbid anatomy, it seems to me, is uniquely difficult to set down in clear-cut terms. This contribution, I think, is being increasingly appreciated, because we are currently witnessing a wave of physiologic research in diabetes which parallels that of the early 1920's and which is of spectacular magnitude and of concern to the pathologist, as well as the physiologist. The fundamental theories of the mechanism of diabetes which we were taught are being seriously challenged. For example, the concept that the diabetic patient is unable to utilize sugar adequately, the concept that ketone bodies are formed because of this inadequate utilization of sugar, and the concept that the pancreas is the key organ in the diabetic, all of these are being threatened with major modifications. There is much impressive evidence—contributed in large

measure by Soskin, Mirsky, and Chaikoff—which points to the liver as the key organ and places the difficulty of the diabetic not so much in his inability to use sugar but in his overproduction of sugar and ketone bodies by a prodigal liver. The effect of anterior pituitary extract in producing a temporary or permanent diabetes in laboratory animals is another remarkable advance. A permanent diabetic state can be produced in these animals in from two weeks to two months, depending on the size of the dose. With the use of this extract, certain changes are seen in the islands and in other organs which remain to be studied by the pathologist. Incidentally, I may be wrong but I believe that partly on the basis of the diabetogenic action of anterior pituitary extract in insulin-treated depancreatized animals it is presumed that the hypophyseal hormone acts not directly on the pancreatic islets but as an antagonist to insulin. It has been shown by Best and his associates and by others that this diabetic state and the changes in the pancreas of the animals so rendered by anterior pituitary extract may be influenced favorably by certain factors—namely, the administration of insulin, high fat diet and low carbohydrate diet, and fasting—and that these changes may be influenced unfavorably by a high carbohydrate diet. And that brings us to the point raised by Haist, Campbell, and Best that perhaps we have in these facts a basis for hope, a provocative hope, indeed, for the prevention of diabetes in children who have a hereditary predisposition thereto.

As far as the kidney is concerned, some five years ago Kimmelstiel and Wilson described a peculiar lesion of the glomerulus of the kidney in association with diabetes mellitus. This was an alert observation. I suppose it is surprising that this correlation has been overlooked for decades. However, this situation is by no means unique, the juxtaglomerular apparatus of Goormaghtigh and the pathology of lupus erythematosus, which is being clarified at the present day, are additional examples of structures and lesions whose significance is just beginning to be understood. Dr Siegal, I think very astutely, became aware of the clinical entity even before he was made aware of the pathologic counterpart. At his bidding Dr Klemperer with his characteristic and inspiring receptivity to new thoughts—I know this embarrasses him, but that is how I feel toward him—asked us to see what the lesion had to offer. There are several points about it

which might be commented upon. First, there is the matter of frequency. One does get a bit of a discrepancy in the incidence reported by different observers of even a less equivocal lesion than the intramural glomerulosclerosis of the kidney, but I should like to emphasize that we have included among our positives—and perhaps Dr Warren has, too—kidneys in which one or two glomeruli were involved by a single lesion, the lesions, when they are found, being characteristic even though only a single lesion is present.

The question of specificity is a curious one. If you comb the literature and the verbal reports on the subject, you find workers who run the whole gamut from those who insist the lesion does not occur in nondiabetic patients—and there is plenty of evidence for that in the published reports—to the rare investigator who feels that the lesion occurs in as high a proportion of nondiabetic as in diabetic patients. That is a remarkable state of affairs, and the most disconcerting part of it is that those on the other (nonspecific) side of the range are competent observers for whose ability we, of course, have a genuine respect. That makes the problem all the more baffling. I do not know the answer, but I have this suggestion to make. In Kimmelstiel's original description of the lesion it was reported as simply an advanced stage of senile, as he called it, senile glomerulosclerosis. He regarded it as differing in no qualitative way from the ordinary aging process. We do not happen to agree with this, because, for one of many reasons, one should expect to find these lesions in great abundance, especially in the most senile, severely contracted kidneys. This is not compatible with what we do find, but you can understand that if pathologists regard the lesion as qualitatively similar to senile glomerulosclerosis then the range of the lesion is widened considerably. We have a definite concept of what the lesion is and, if I were to give a series of slides to another pathologist with a morphologic impression of the lesion similar to our own, as was done (New York Pathological Society, New York State J Med 41:1482, 1941), I think we should find about the same percentage of lesions, because we have a narrow and clear-cut conceptual scheme of what the hyaline is, where it is placed, and how the vessels around it are constituted.

The question of the nature of the hyaline is again interesting. We, of course, wondered whether the hyaline within the glomerulus was identical with the hyaline in the islands

Discussion

DR ARTHUR C ALLEN. I want to state at the outset in all genuineness that there are many pathologists here who are more adequately equipped than I to discuss a paper on the pathology of diabetes or any other of a variety of papers which Dr Warren might have chosen to present before this Society. But this much I am sure of: he has rendered a real service in his compilation and evaluation in the past few years of the facts of the pathology of a disease whose morbid anatomy, it seems to me, is uniquely difficult to set down in clear-cut terms. This contribution, I think, is being increasingly appreciated, because we are currently witnessing a wave of physiologic research in diabetes which parallels that of the early 1920's and which is of spectacular magnitude and of concern to the pathologist, as well as the physiologist. The fundamental theories of the mechanism of diabetes which we were taught are being seriously challenged. For example, the concept that the diabetic patient is unable to utilize sugar adequately, the concept that ketone bodies are formed because of this inadequate utilization of sugar, and the concept that the pancreas is the key organ in the diabetic, all of these are being threatened with major modifications. There is much impressive evidence—contributed in large

40 When we corrected the incidence for the patients over 40, the relative incidence by sex remained the same, the overall incidence rose to 18 per cent. The highest incidence remained in women, in the corrected groups, at 23 per cent.

Having found these cases, we graded them according to the severity and extent of the lesion. Four of them were most severe and, taking an arbitrary designation, we called them 3 plus. All 4 of the 3 plus cases showed the complete clinical syndrome. It was interesting that among the 4 there were 2 that had been previously diagnosed as having amyloid disease. This brings me to the point that in the differential microscopic diagnosis the resemblance to amyloid is striking in preparations stained with hematoxylin and eosin. But there can be no doubt on differential staining that the lesions in the glomeruli are actually hyaline connective tissue, they stain like mature hyaline collagen.

The other cases fell into groups of 2 plus and 1 plus, and there was a small group with focal lesions in which a single glomerulus in a low-power field might show one of these hyaline spheres. These cases were found among individuals who did or did not have hypertension and who had diabetes of varying severity, some so slight as to require no management other than diet, some had diabetes so severely as to require 40 to 60 units of insulin per day.

In the 12 positive cases that were analyzed in detail, we could not find a correlation with the clinical severity of the diabetes, the duration of the diabetes, or its management. I mention this simply to emphasize the point I made first—that diabetes mellitus in these patients may be a waxing and waning disorder of a nature unrelated to any disturbance in renal function. Some of the patients presented themselves at the hospital with complications related to the disease—e.g., gangrene of the extremities in 2 patients, cardiac failure in 2 additional patients, pyelonephritis was present in several, and frank pus in the urine was encountered without particular reference to the grade of the special glomerular lesion. There was one thing that all had in common, a finding that I hope to hear Dr. Warren or Dr. Allen comment upon perhaps a little later. They all had arteriosclerosis, whether they had an isolated glomerular lesion or a universal glomerular lesion. And this was universal, even in the mildest cases. This had raised

the question in my mind whether this is a prerequisite to the development of this peculiar intercapillary glomerular body.

It was interesting to review the matter of gross diagnosis in these patients. As the clinicians have become aware of the disease, several patients have come to autopsy with the clinical diagnosis of intercapillary glomerulosclerosis. They were patients who had the syndrome of diabetes, hypertension, and the "nephrotic" state. In 2 patients the diagnosis was confirmed at autopsy, but only on microscopic examination. I do not know how to make the gross diagnosis of this disorder. Some patients had normal kidneys on gross inspection, some had arteriosclerotic scars. Most exhibited the same appearance as the kidneys in moderately advanced arteriolonephrosclerosis. Some had moderate amounts of lipid material deposited in the parenchyma.

While the gross diagnosis is unattainable, the microscopic diagnosis is not so difficult, particularly in the mildest cases, but even in the severe cases it is possible to find glomeruli scattered about which show this peculiar hyaline sphere to be unrelated to the other changes in the glomerulus. But when one encounters a glomerulus that has been replaced by connective tissue, I do not see how you can tell the process by which it has reached this stage. It seems likely that the end-stage lesion will often be the source of dispute among observers. It is also likely that a variety of lesions in the glomerulus might produce a hyaline collagenous deposition. I am reminded of the Löblum lesion, which is quite distinctive when it is found attached to the parietal capsule, but it may be an isolated lesion in the glomerulus. Finally, one may find necrotizing lesions like those seen in malignant hypertension, thrombosis, or necrosis of the capillary loops associated with necrosis of afferent arteriolar walls with intramural hemorrhage. In this connection 3 of the 4 severe cases we found had microscopic hematuria in their urine specimens.

I believe that at this stage in the development of a new subject it is wise to wait and see about the specificity of these lesions in the diabetic subject. They certainly stimulate interest anew in the possible morphologic changes in this disorder. For my own part, I think Dr. Warren has conspicuously served to stimulate all of us to re-examine the widespread morphologic problems of a disease in which, although there is an effective thera-

of Langerhans, and we do not think it is quite the same. For example, we have derived a good deal of information from the study of this lesion with silver stains, the capriciousness of which I am well aware. We find there is a marked argyrophilia in the renal lesions, we do not find a corresponding argyrophilia in the hyalinized islands of Langerhans.

I think perhaps the most intriguing part of the lesion is the sclerosis of the efferent arteriole. We know the pressor substance in hypertension is assumed to act in great measure by constriction of the efferent arteriole (Merrill, A., Williams, J. R., Jr., and Harrison, T. R. *Am. J. M. Sc.* 196: 240, 1938; Corcoran, A., and Page, I. H. *Am. J. Phys.* 126: 354, 1939), thereby raising the intraglomerular pressure and modifying the glomerular dynamics. We know, too, that there is a higher incidence of hypertension among diabetic patients than among other people of a corresponding age group. Here we have the efferent arterioles frequently organically narrowed, especially in association with the intramural glomerulosclerosis, and we wonder about the relationship. In addition, it is pointed out in the literature (McGregor, L. *Am. J. Path.* 6: 347, 1930) that the renal efferent arterioles of ordinary hypertensives are morphologically normal. In chronic glomerulonephritis this vessel seems also to be unchanged, as shown by the remarkable plastic studies of Dr. Jean Oliver and his associates (Oliver, J. R., and Lund, E. M. *Arch. Path.* 15: 755, 1933). This finding in itself would constitute a significant difference between some of the diabetic and the nondiabetic kidneys. Because of the influence of the efferent arteriole on glomerular dynamics, we should be much interested in clearance studies of these patients.

What I am trying to say, in brief, is that I can hardly subscribe to the view of those who feel that the future of pathology lies in simply extending the answers, the already well-formulated answers, to additional decimal places. I do not believe that is true for a whole host of diseases, I am certain that it does not hold for diabetes mellitus.

DR. IRVING GRAEF. It is a pleasure to salute the masterly presentation that Dr. Warren has given us of the problems and some of the facts about the lesions we may see in diabetes mellitus. I do not think we can make any summary conclusions about work to be done. I think it is fair to say, however, that diabetes mellitus remains a clinical diagnosis and that it is a disease of metabolism

in which the morphologic substrate has yet to be identified. I think that we would all do well to remember, certainly as pathologists, that diabetes mellitus as a clinical disease waxes and wanes. Experience with patients may represent only the terminal phase of a physiologic disorder that itself may be years in duration or actually only hours in duration. And, here again, calling all persons who have glucose or reducing bodies in their urine and a large quantity of glucose in their blood diabetic patients may mislead us when it comes to interpreting their morphologic findings. It can hardly be safe to compare those individuals who have been known to have this disorder for a long period with individuals who merely have a premortal hyperglycemia or glycosuria, perhaps even clinically unknown.

When Kimmelstiel and Wilson's lesion first came to attention, many interested in morphologic pathology were intrigued by the notion that this disorder might be a new form of glomerular alteration. But opinion was withheld, and no consensus has developed yet that this disorder, as such, is primarily related to the disturbance of carbohydrate metabolism, which was associated with the disorder as described by Kimmelstiel and Wilson in all but one of their cases. Since then, a number of persons have surveyed their material and their experience, and I think the opinion is growing (and Dr. Warren has given voice to this opinion) that this peculiar glomerular lesion is found most frequently in persons who have had clinical diabetes mellitus. The occasional patient who lacks the clinical record of diabetes mellitus may be the individual who has had it and has spontaneously become rid of it or who comes to autopsy at a time when its clinical manifestations are in abeyance. Its occurrence in hypertension is extremely interesting. A few cases are accumulating in different series in nonhypertensive patients.

I thought it might be interesting to tell you what a brief survey has shown in 75 unselected cases of diabetes mellitus which came to necropsy at Bellevue Hospital. These patients consisted of 36 men and 39 women ranging in age from 17 to 85 years. The incidence in the men was one-half of that in the women, there being 4 cases among the men and 8 cases among the women. Together they made an overall incidence of 16 per cent. We noticed that the incidence of positive cases of intercapillary glomerulosclerosis—or intramural glomerulosclerosis, as Dr. Allen likes to call it—was limited to patients over

40 When we corrected the incidence for the patients over 40, the relative incidence by sex remained the same, the overall incidence rose to 18 per cent. The highest incidence remained in women, in the corrected groups, at 23 per cent.

Having found these cases, we graded them according to the severity and extent of the lesion. Four of them were most severe and, taking an arbitrary designation, we called them 3 plus. All 4 of the 3 plus cases showed the complete clinical syndrome. It was interesting that among the 4 there were 2 that had been previously diagnosed as having amyloid disease. This brings me to the point that in the differential microscopic diagnosis the resemblance to amyloid is striking in preparations stained with hematoxylin and eosin. But there can be no doubt on differential staining that the lesions in the glomeruli are actually hyaline connective tissue, they stain like mature hyaline collagen.

The other cases fell into groups of 2 plus and 1 plus, and there was a small group with focal lesions in which a single glomerulus in a low-power field might show one of these hyaline spheres. These cases were found among individuals who did or did not have hypertension and who had diabetes of varying severity, some so slight as to require no management other than diet, some had diabetes so severely as to require 40 to 60 units of insulin per day.

In the 12 positive cases that were analyzed in detail, we could not find a correlation with the clinical severity of the diabetes, the duration of the diabetes, or its management. I mention this simply to emphasize the point I made first—that diabetes mellitus in these patients may be a waxing and waning disorder of a nature unrelated to any disturbance in renal function. Some of the patients presented themselves at the hospital with complications related to the disease—e.g., gangrene of the extremities in 2 patients, cardiac failure in 2 additional patients, pyelonephritis was present in several, and frank pus in the urine was encountered without particular reference to the grade of the special glomerular lesion. There was one thing that all had in common, a finding that I hope to hear Dr. Warren or Dr. Allen comment upon perhaps a little later. They all had arteriosclerosis, whether they had an isolated glomerular lesion or a universal glomerular lesion. And this was universal, even in the mildest cases. This had raised

the question in my mind whether this is a prerequisite to the development of this peculiar intercapillary glomerular body.

It was interesting to review the matter of gross diagnosis in these patients. As the clinicians have become aware of the disease, several patients have come to autopsy with the clinical diagnosis of intercapillary glomerulosclerosis. They were patients who had the syndrome of diabetes, hypertension, and the "nephrotic" state. In 2 patients the diagnosis was confirmed at autopsy, but only on microscopic examination. I do not know how to make the gross diagnosis of this disorder. Some patients had normal kidneys on gross inspection, some had arteriosclerotic scars. Most exhibited the same appearance as the kidneys in moderately advanced arteriolonephrosclerosis. Some had moderate amounts of lipid material deposited in the parenchyma.

While the gross diagnosis is unattainable, the microscopic diagnosis is not so difficult, particularly in the mildest cases, but even in the severe cases it is possible to find glomeruli scattered about which show this peculiar hyaline sphere to be unrelated to the other changes in the glomerulus. But when one encounters a glomerulus that has been replaced by connective tissue, I do not see how you can tell the process by which it has reached this stage. It seems likely that the end-stage lesion will often be the source of dispute among observers. It is also likely that a variety of lesions in the glomerulus might produce a hyaline collagenous deposition. I am reminded of the Löblen lesion, which is quite distinctive when it is found attached to the parietal capsule, but it may be an isolated lesion in the glomerulus. Finally, one may find necrotizing lesions like those seen in malignant hypertension, thrombosis, or necrosis of the capillary loops associated with necrosis of afferent arteriolar walls with intramural hemorrhage. In this connection 3 of the 4 severe cases we found had microscopic hematuria in their urine specimens.

I believe that at this stage in the development of a new subject it is wise to wait and see about the specificity of these lesions in the diabetic subject. They certainly stimulate interest anew in the possible morphologic changes in this disorder. For my own part, I think Dr. Warren has conspicuously served to stimulate all of us to re-examine the widespread morphologic problems of a disease in which, although there is an effective thera-

peutic agent, the pathogenesis is still a challenge

DR SHIELDS WARREN I appreciate very much the interest in diabetes that has been shown by all of you and particularly by those of you who have taken part in the discussion

The problem, as you can see from what I have said and from what has been presented by others, is as yet far from solved, although we are steadily getting closer and closer to the fundamental truths that will help us to a

proper solution, I hope, of the entire problem of disturbed carbohydrate metabolism. One particular thing I should like to stress a little more and that is the point that Dr Graef clearly brought out—diabetes is a disease that shows remarkable fluctuations in its severity and a disease that may at times be unrecognized clinically and may show little relationship between the pathologic picture it presents and the severity it shows in the sick individual who ultimately comes to the postmortem

COMPLAINT TO THE AMERICAN MEDICAL ASSOCIATION*

(Concerning their members' unfair monopoly of best selling autobiographies and other fiction)

Of all God's creatures here below

Whose feats confound the skeptic

I most admire the Medico,

That hero antiseptic

He has my heart, he has my hand,

He has my utmost loyalties

(He also has my tonsils and

A lien on my royalties)

For from the time he doth begin

His sacred tryst with medicine,

How noble, he! How never-tiring!

Nor rain, nor heat, nor maids admiring,

Nor bills unpaid, nor farmers' hounds

Can stay him from his sleepless rounds

More fleet than winners of the Bendix,

He hastens to the burst appendix,

Or breasts the blizzard cold and shivery

To make some rural free delivery

Or if to ampler orbits whirled

(As fate will sometimes toss us),

How he bestrides this narrow world,

A medical Colossus!

Perhaps, his kit upon his back,

He dares the jungle thickets,

Intent upon the fevered track

Of yaws or mumps or rickets

The chum of kings, the friend of presidents,

He makes the earth his private residence,

One day prescribing pills and pickups

To cure an emperor of hiccups,

The next in stricken cities stranded,

Combatting scourges single-handed,

At peril of life, at risk of limb

Yet do such deeds suffice for him?

No, no In secret all the while

He's sought a Literary Style

The pen (so springs the constant hope

Of all devout physicians)

Is mightier than the stethoscope

And runs to more editions

So while he's waged bacillic wars,

Or sewed a clever suture,

His mind has hummed with metaphors

Laid up against the future

Amid the knives and sterile gauzes

He's dreamt of modifying clauses,

And never gone to bed so late

His diary wasn't up to date,

As if he'd sworn an oath to follow

Both Harper Brothers and Apollo

Oh, more than Einstein, more than Edison

I do admire the man of Medison

He has my hand, he has my note,

He has those X-rays of my throat,

But is it fair he should lay claim to

The overcrowded writing game, too?

I eye askance those dubious laurels

Where are his ethics? Where his morals?

In what brave school did he matriculate

That he should be so damned articulate?

And where's the seal to show his betters

He's certified a Man of Letters?

Professional sirs, I gravely doubt,

In any really nice sense,

Your boys should practice thus without

Their literary license

—Phyllis McGinley

NEW TB PROJECT

The x-raying of all patients and employees of New York State hospitals for the insane and schools for the feeble-minded is now in progress, according to Dr William J Tiffany, state commissioner of mental hygiene. This is a joint

undertaking of the State Department of Health and Mental Hygiene, under a legislative appropriation of \$45,000, and is but one of several projects of the No-Tuberculosis-After-1960 campaign

TUBERCULOSIS ABSTRACTS

A Review for Physicians

ISSUED MONTHLY BY THE NATIONAL TUBERCULOSIS ASSOCIATION

Vol. XIV

November, 1941

No 11

MORTALITY from tuberculosis has been quartered in forty years. This fact, however, reveals no accurate information regarding prevailing infection and morbidity rates. That they are less is too logical a deduction to be doubted, but their decline relative to that in mortality has been a matter of conjecture. The following report on autopsy findings throws valuable light on this question, especially since accurate studies extending over the past half century furnish the needed controls for comparison.

PREVAILING TUBERCULOSIS INFECTION RATE

In 1900 Naegeli published a careful report of 508 autopsies. Of the adults over 18 years of age 93 per cent showed healed, inactive or active tuberculous lesions in the lungs. Only 17 per cent of those under 18 yielded positive findings. Other investigators substantiated these findings, and in the early years of this century the belief was prevalent that all adults had at some time suffered an invasion by the tubercle bacillus.

Opie, as late as 1917, found positive evidence of infection in all of 50 autopsies on adults and in nearly 24 per cent of a group of 93 children, the latter showing a far higher figure in the adolescent years. It was these findings that led Opie to remark: "Almost all human beings are spontaneously 'vaccinated' with tuberculosis before they reach adult life."

In 1922 Wason reported positive findings in 82 per cent of his autopsies, and in 1925 Lambert and de Castro Filho reported a rate of 72.8 per cent in a large series from Brazil. As late as 1927 Todd still found evidence of tuberculous infection in 69 per cent of autopsies done in Edinburgh on patients who had died of some cause other than tuberculosis. Such evidence indicates rather clearly that the decline in infection rate has not kept pace with mortality from this disease.

The present study was carried on at the Washington County Hospital in Hagerstown from September, 1938, to August, 1940, all autopsies being performed by the same pathologist. There were 176 autopsies during this period, which represented 45 per cent of the deaths that occurred. Eleven of these were rejected because they were not complete postmortems, leaving 165 which are included in this report. Cases of active tuberculosis are not admitted to the hospital. The population of Washington County is semirural and most of the patients were long residents, from all classes of society and of the white race (only four negro adults in the group).

Thirty-two of the 165 necropsies were done on children and 133 on adults. For the whole group positive findings were recorded in 65 or 39.4 per cent, which is just half of Naegeli's findings—79.9 per cent when he included all ages.

Considering only the adult group of 133 cases, the positive evidence of infection yielded 47.4 per cent, again strikingly near one-half the number of adults found to be infected by the earlier researches of Naegeli, Burkhardt, Opie, and others. In this series there were 5 cases where in-

fection was suspected but could not be proved pathologically. If these are included, the percentage would stand at approximately 50.

This finding of almost 50 per cent of positive tuberculosis among an unselected group of a semirural population indicates that the frequency of tuberculosis is still sufficient to be alarming. If one assumes this experience as typical of the country as a whole, which seems reasonable, we must still face the fact that at least half of all adults have suffered invasions by the tubercle bacillus active enough to leave discoverable scars. This is disconcerting in face of the far greater fall in the death rate from the disease.

At the same time there is some compensation in the discovery revealed by this study that only one-half as many people who have suffered tuberculous infection actually die of the disease as was the case forty years ago. The infection rate has been reduced to 50 per cent, the mortality to 25 per cent of that in 1900. A number of factors have probably contributed to this gratifying preponderance in the decline of the death rate. Better sanatorium care and the management of cases has undoubtedly made a large contribution. The fact that lessening of the infection rate has apparently shown acceleration in the past fifteen or twenty years brings comfort to those engaged in the preventive and therapeutic aspects of tuberculosis control. A 50 per cent reduction in the reservoir of spreaders must certainly mean that fewer contact cases are today submitted to massive and repeated doses of infected material. The contribution of compression therapy and surgery to this result can but be inferred. Those who advocate freer use of these measures certainly would seem to have little for which to apologize in the evidence presented by this study.

However, there are other factors in the picture which perhaps deserve first mention. Isolation is the time-honored scheme for the control of epidemic, infectious disease. It is a significant coincidence that during the period when tuberculosis mortality was reduced to one-quarter its 1900 level and infection rate cut by 50 per cent the sanatorium beds in this country increased from about 6,000 to 100,000. It would be idle not to recognize this prophylactic procedure as an outstanding influence in lessening opportunity for infection among the general public.

The result of this procedure would have been far more striking had it been possible to arouse

the medical profession to its responsibility in finding the early case and effecting its immediate isolation. Unfortunately, this is one of the weaker links in our control program. From three-quarters to four-fifths of all cases admitted to sanatoriums are still found to be in the advanced stages of the disease, already probable spreaders of the infection to others. More professional education, both undergraduate and postgraduate, is still needed to impress upon physicians how truly further progress in tuberculosis control rests in their hands.

Popular health education and school hygiene have also played their parts in reducing opportunities for infection. Beginning with teaching the infectivity of sputum, the transference of disease through common utensils, uncleanness in restaurants, the menace of infected food handlers, instruction has proceeded to the point where even an open case is of relatively little danger to his fellows if both he and they will exercise the prophylactic measures now recognized as largely effective.

Finally, better housing, elimination of industrial hazards, more applied knowledge of the laws of nutrition, and a growing consciousness of the significance of personal and community hygiene, all have played their part in reducing the transmission of tuberculous infection from case to contacts.

A highly significant factor in this study is the observation that reduction of infection as shown at autopsy has been at least as rapid among infants and children as among adults. These younger members of society can make no personal contribution to their own protection.

They must rely on that of others, nurses, teachers, parents, and relatives. Cutting their infection rate in two as well as that of their elders is clear proof that a better informed public is making an increasingly effective fight against spread of this disease.

Frost in discussing the eradication of tuberculosis wrote as follows: "Tuberculosis also differs from the other directly transmitted respiratory tract infections in that its mortality has declined consistently for the last fifty years or more and continues to decline in every part of this country for which adequate statistics are available. It is not directly established by comparable statistical evidence that there has been a proportionate decrease in the prevalence of infective cases of the disease, taking into consideration not only the number of cases but duration of the open stage. However, there appears to be no good reason to doubt that the prevalence of open lesions effective in spreading the tubercle bacillus has diminished progressively and continues to diminish in each considerable period of time."

However, it must not be overlooked that according to present autopsy records the reservoir of adults infected with tuberculosis at one time or another in their lives still amounts to half of the population. Therefore, tuberculosis can still flare up again whenever external conditions turn to the worse for the bulk of the people. Without such a reverse there exists the hope that further efforts in the campaign against tuberculosis will some day lead to a complete eradication of the white plague.—*Lande, Kurt E., and Wolff Georg. Am. Rev. Tuberc. 44 No. 2 (Aug) 1941*

MATERNAL WELFARE

A report of a six-year study of the Maternal Welfare Committee of the Medical Society of the County of Erie will be given in Buffalo at the Buffalo Museum of Science, Humboldt Park, on Wednesday, December 17, at 8:45 P.M. It is presented under the auspices of the Buffalo Academy of Medicine, the Maternal and Child Welfare Committee of Erie, Niagara, Cattaraugus, Genesee, and Wyoming county medical societies, the University of Buffalo School of Medicine, the Division of Maternity, Infancy and Child Hygiene, New York State Department of Health, and the Medical Society of the State of New York.

Dr. Louis A. Siegel, secretary of the Maternal Welfare Committee of the Medical Society of the County of Erie, will have as his subject "Maternal Mortality in Buffalo." During Dr. Siegel's six years as secretary of this committee

he has analyzed over 300 maternal deaths and has published two interval reports in the *JOURNAL*. His six-year report, now in preparation, will be published in the *J.A.M.A.*

Dr. Francis C. Goldshorough, professor of obstetrics and gynecology, University of Buffalo School of Medicine, will speak on "Indications and Contra-Indications for Cesarean Section." Each year the Maternal Welfare Committee has stressed the fact that over 50 per cent of the maternal deaths occur in the cesarean-section group. Dr. Goldshorough will discuss the recognized indications for this operation. He will point out the dangers of section as shown by the investigation of maternal deaths in Buffalo.

Discussion of these papers will be opened by Dr. Karl Miller Wilson, professor of obstetrics and gynecology, University of Rochester School of Medicine and Dentistry.

ONE FOR THE KNEADY

"What is college bred, Pop?"

"College bred, my son, is made from the flower of youth and the dough of old age."

Medical News

County News

Albany County

The annual dinner and dance will be held at the DeWitt Clinton Hotel in Albany on December 17. The publicity announces "Good fellowship—novel and unusual entertainment—and No War Speeches."

At the meeting of the county society on November 26, Dr. Nathan Chandler Foot talked on "Mammary Tumors."

Bronx County

Dr. Foster Kennedy, of New York City, spoke on "Neuroses and War" at the meeting of the society on November 19. Dr. Joshua H. Leiner and Dr. Edward P. Flood led the discussion.

Broome County

Broome County health and medical organizations, hospitals, and field workers are ready for almost any sabotage or war emergency, says Dr. Ralph M. Vincent, district health officer. A survey of available medical facilities in the county indicates that a vast amount of work has been done by the various organizations—the county medical society, the medical preparedness committee, the Red Cross, as well as others.

Although the survey is still in progress, Dr. Vincent said that at present, through the combined efforts of these agencies, it is believed that the residents of any locality in Broome County would be reached quickly by medical, nursing, and first-aid personnel and that hospitalization would be provided, if necessary.

Canandaigua County

At the meeting on November 13 Dr. Leon A. Stetson spoke on "Public Health in the Preservation of Democracy."

Columbia County

A dinner that marked the beginning of an intensified campaign to wipe out tuberculosis in Columbia County was held on November 24 at the General Worth Hotel in Hudson and was attended by 180 people. Dr. Harry A. Pattison was in charge of arrangements.

Dr. Edward S. Godfrey, Jr., state commissioner of health, Dr. Peter Irving, executive secretary of the New York State Medical Society, and Dr. Kendall Emerson, director of the National Tuberculosis Association, were the speakers for the occasion that opened the Christmas Seal sale in the county.

Great enthusiasm was manifested for the new expanded program. Dr. Irving stressed the wider opportunity that practicing physicians will have for case-finding among contacts with the aid of the Department of Health.

Dutchess County

The Hudson Valley Surgical Guild of the International College of Surgeons, in cooperation with St. Francis Hospital, Poughkeepsie, held an all-day meeting on December 4. Doctors from nearby states attended the meeting which

took the form of a symposium on cancer with eminent speakers in that field. Dr. Max M. Simon, president of the guild, was in charge of the meeting and was assisted by Dr. J. E. McCambridge, Dr. J. J. Toomey, and Dr. R. J. Boyce.

Erie County

The doctors of Akron have increased their fees—effective December 1. The new fees are \$2.00 for office calls, \$3.00 for home calls in the village, and \$3.00 (plus mileage) for country calls.

See opposite page for the report of the Maternal Welfare Committee which will be given on December 17 in Buffalo.

Fulton County

The November meeting of the county society was held on November 13 at the Eccentric Club in Gloversville.

The speakers included Dr. J. R. Ross, superintendent of the Harlem Valley State Hospital at Wingdale, Dr. I. M. Rossmann, senior assistant in the hospital, and Dr. H. A. La Burt, assistant superintendent of the institution. The pictures were made, arranged, and shown by Fred Neilson, of Nassau.

Neilson is troubled with an affliction of the legs and some time ago took up photography, specializing in colored motion pictures. The one picture deals with the insulin shock treatment for dementia praecox. The various stages of the treatment were explained by the visiting physicians. The intimate views of operations and treatments showed the great skill of the photographer.

Herkimer County

Adequate medical care cannot be given county relief clients on the basis of the present fee schedule adopted in April for a six-month trial period, the county society declared on November 13 at a special session in the Mohawk Valley Country Club in Herkimer.

The society discussed the minimum medical fee schedule in the regular nonwelfare cases and decided, because of the increased cost of materials and supplies and the higher cost of living generally, to adopt slight increases, effective December 15. The state workmen's compensation fee schedule will be used as a basis.

The change will probably increase minimum office call charges from \$1.50 to \$2.00. House calls will either remain at \$2.00 or be slightly increased, but night calls will go to \$3.00.

Because of the charitable nature of welfare work, the doctors adopted a resolution allowing 25 per cent reduction from the new schedule on all welfare bills, except house and hospital calls, which will remain at \$2.00. Under the present system, \$1.00 a day is allowed for hospital calls daily for five days and every other day thereafter.

Jefferson County

At the annual meeting of the society held in November the following officers were elected: president, Dr E Clifford Soultz, of Carthage, vice-president, Dr Sutherland E Simpson, of Watertown, treasurer, Dr James L Crossley, of Watertown, secretary, Dr Charles A Prudhon, of Watertown, censors, Drs Frederic R Calkins, of Watertown, Harold Gokey, of Alexandria Bay, James E McAskill, of Watertown, Harlow E Ralph, of Belleville, Jesse R Pawling, of Watertown

Kings County

The committee planning the annual dinner to the ex-presidents reports that the dinner will be held on Saturday, January 17, at the Hotel St George. At this dinner each living ex-president will be presented with a medal and scroll. There will be two prominent speakers and the doctors' orchestra will play.

The committee consists of Drs Charles A Gordon, chairman, Frank B Doyle, vice-chairman, Ignatius P A Byrne, secretary, and Charles F McCarty, treasurer—other members are Drs William C Meagher, Leo S Schwartz, H Tevel Zankel, and Mrs Louis I Harris.

In response to many requests of its members, the society is now organizing its own swing band, according to the *Bulletin*. In addition, there is a symphony orchestra, a billiard club, a doctors' choir, and a Magic Circle for doctors interested in developing magic as a hobby. The members responsible for these activities are to be congratulated, for in the present-day rush it is easy not to find time for hobbies, which are just as important for doctors as for laymen.

The pediatric section of the county society will hold a meeting on December 22 at 8:30 p.m. at 1313 Bedford Avenue, Brooklyn. Dr Brett Ratner, of New York City, will talk on "Allergy in Pediatric Practice."

Lewis County

The following officers were elected at the annual meeting of the society held in Lowville on October 29: president, Dr David J O'Connor, of Croghan, vice-president, Dr Edgar O Boggs, of Lowville, secretary-treasurer, Dr Elbert Dalton, of Beaver Falls, censor for three years, Dr Bruce M Phelps, of Lowville, delegate to state convention, Dr Dalton, alternate, Dr Boggs, representative to the staff, Dr Thomas A Lynch, of Lowville.

Monroe County

Dr Rufus B Crane of the medical staff of Eastman Kodak Company and Dr G Kirby Collier, psychiatrist and chairman of the committee on nervous and mental diseases of the county society, addressed the Rochester branch of the Vocational Guidance Association held last month. The speakers urged the application to candidates for jobs in industry of a plan of rehabilitation similar to that being used by the Selective Service Administration to cut down the rate of rejections for mental and physical ailments.

Dr Crane pointed out that the Selective Service Administration is sending letters to all

men registered under the draft urging them to consult family doctors and dentists if they believe themselves below the required standard and to follow treatment prescribed.

At the meeting of the county society, the Rochester Academy of Medicine, and the University of Rochester Medical School, held in the Academy auditorium on November 30, Dr Donovan J McCune, Babies Hospital, New York City, spoke on "Food Requirements for Health."

Nassau County

The monthly meeting of the society was held on November 25 at Cathedral House, in Garden City. Dr Yale Kneeland, Jr, assistant professor of medicine at Columbia, spoke on "Chemotherapy."

Listed in the *Bulletin* are the following future events of the society:

January 19 Joint Meeting with Nassau County Dental Society. Topic: The Relation of Systemic Diseases to Infections of the Oral Cavity. Speakers: Russell L Cecil, M.D., professor of clinical medicine, Cornell University Medical College, Daniel E Ziskin, D.D.S., director, Department of Oral Diagnosis, School of Dental and Oral Surgery, Columbia University.

February 24 Joint Meeting with the Woman's Auxiliary to the Nassau County Medical Society. Topic: Mental Hygiene. Speaker: Richard M Brckner, M.D., Neurological Institute, Vanderbilt Clinic, and Mount Sinai Hospital.

March 31 Symposium on Surgery, presented by the Nassau Surgical Society.

April 28 Symposium on Tuberculosis, presented by the Nassau County Sanatorium.

May 26 Annual Meeting. Topic: The National Nutrition Program. Speaker to be announced.

The annual dinner dance was held this year on December 6 at the North Hempstead Country Club.

New York County

On November 24 the following officers were elected for the coming year: president, Dr Maximilian A Ramirez, president-elect, Dr J Stanley Kenney, first vice-president, Dr Conrad Berens, second vice-president, Dr Francis N Kimball, secretary, Dr B Wallace Hamilton, assistant secretary, Dr John Carroll, treasurer, Dr Fenwick Beekman, assistant treasurer, Dr Howard C Taylor, Jr, censors (for three years), Dr Samuel B Burk and Dr Roy B Henline. The chairmen of committees are as follows: legislation, Dr John B Lauricella, public relations, Dr W Bayard Long, medical economics, Dr William B Rawls, and membership, Dr Carl Binger. Dr Albert H Aldridge was elected a trustee (for five years). The delegates to the State Society are Drs W P Anderton, Emily D Barringer, Conrad Berens, Harold B Davidson, Vincenzo Fanoni, W Travis Gibb, Jr, Roy B Henline, J Stanley Kenney, John B Lauricella, Madge McGuinness, Maximilian A Ramirez, Nathan Ratnoff, and William B Rawls.

Dr Annie S. Daniel, for sixty years a member of the staff of the New York Infirmary for Women and Children, New York City, was recently honored at a dinner by one hundred graduates of the infirmary, several of whom studied under her in the eighteen eighties. Dr Daniel, who gives her age as 80 plus, is still in charge of the infirmary's outpatient service.

Niagara County

Inadequate public health nursing service and lack of laboratory facilities in the rural areas of the county were discussed by members of the county society at a recent meeting at the Niagara County Sanatorium at Lockport. A resolution dealing with conditions was offered by Dr W. A. Peart, of Sanborn, health officer of the town of Niagara.

Health authorities of the county have been engaged for some time in the task of enlarging the public health nursing service, and the physicians are expected to offer new evidence of the need for more nurses. The shortage of laboratory facilities is said to be a great handicap to physicians in rural areas. They are unable to confirm diagnoses without resorting to the use of equipment in city hospitals, the delay frequently resulting in serious consequences for their patients. The situation, it is claimed, is particularly serious in the case of expectant mothers who are denied adequate prenatal care.

Queens County

At the annual meeting of the county society on November 25 the following officers were elected: president, Dr Chester L. Davidson, of Jamaica; president-elect, Dr Jacob Werne, of Jamaica; secretary, Dr Ezra Wolff, of Forest Hills; assistant secretary, Dr Paul Shuey, of Jackson Heights; treasurer, Dr John J. Sheehy, of Hollis; assistant treasurer, Dr Robert Yanover, of Flushing; historian, Dr W. Guernsey Frey, Jr., of Forest Hills; directing librarian, Dr Elmer Kleefeld, of Forest Hills; assistant directing librarian, Dr Alfred Angrist, of Jamaica; trustees are Dr d'Angelo, Dr Vincent Juster, of Jamaica, and Dr Walter Lynn, of Forest Hills. The censors are Dr Joseph Lanza, of Long Island City; Dr John Keating, of Rego Park; Dr David Lothringer, of Jamaica; and Dr Amadeo dePoto, of Jamaica. The delegates are Dr d'Angelo and Dr Joseph Wrana, alternates, Dr C. Nelson Baker and Dr Walter Lynn.

At the Friday Afternoon Talk on December 19 Dr Norman Jolliffe of Bellevue Hospital will speak on the "Relation of Vitamins to Disease."

"Art as a Hobby for the Busy Doctor" is the heading of a notice in the *Bulletin* that invites all members of the society to join the art club. The club has a well-equipped studio in the society's building in Forest Hills, and an art instructor is provided. The announcement concludes: "Group outings to rustic and peaceful environments are contemplated where, rolling hills, drooping foliage, and humming streams will inspire us to interpret 'nature in the raw'."

Rensselaer County

At the annual dinner meeting on December 10,

held in Troy, Dr Haven Emerson spoke on "Administrative Medicine."

Schoharie County

"Tuberculosis, like a thief in the night, robs a man of his health when he is least aware of its presence. Every physician realizes the need of educating the layman to the dangers that lie in one undetected person with tuberculosis. The germs from that one person may spread to half a dozen persons," said Dr Roy G. S. Dougall, president of the county society, at the opening of the Christmas Seal sale of the Schoharie County Tuberculosis Association.

The Boy Scouts are participating in the campaign by putting up posters. In the words of one Eagle Scout: "We're covering this town like a blanket."

Steuben County

At the annual meeting held on November 13 in the Hotel Wagner in Bath, Dr Joseph B. Mathewson, of Bath, was elected president.

Other officers are: vice-president, Dr Stuart H. Bean, Addison; secretary-treasurer, Dr Rudolph J. Shafer, Corning; censors, Dr D. Roger Haggerty, Arkport, and Dr James J. Sanford, Bath. Delegates to the State Society meeting are: first district, Dr Herbert B. Smith, Corning, alternate, Dr Edwin H. Ober, Painted Post; second district, Dr Leon M. Kysor, Hornell, alternate, Dr William J. Tracy, Hornell.

Dr Ernest Lampe, Cornell University, gave a paper on "Tendon and Nerve Injuries."

Tioga County

A series of nutrition classes is being held in Owego, sponsored by the Parent-Teacher Association and the Public Health Association. Dr Ivan N. Peterson, secretary of the county society, will be the speaker for the meeting on January 6. His subject will be "The Part of the Community in National Defense."

Washington County

Erratum.—In the November 15 issue the board of censors and the chairman of the legislative committee were incorrectly listed. The board of censors consists of Dr W. C. Cuthbert, of Hudson Falls; Dr C. H. Holmes, of Cambridge; and Dr K. Creevey, of Cambridge. The chairman of the legislative committee is Dr W. A. Leonard, of Cambridge.

Westchester County

A course in general medicine has been arranged for the county society by Dr Walter W. Palmer, College of Physicians and Surgeons, Columbia University, New York City. The meetings will be held at the New York Hospital, Westchester Division, White Plains, at 8:30 p.m.

On January 14 Dr Dana W. Atchley, associate professor of medicine, College of Physicians and Surgeons, will speak on "Nephritis." Dr Albert Vander Veer, consultant in allergy, Roosevelt Hospital, and assistant director of the Allergy Clinic, New York City, will lecture on "Asthma" on March 11. The third lecture will be given on May 13 by Dr Homer F. Swift of the Hospital of the Rockefeller Institute for

Medical Research. His subject will be "Rheumatic Fever." This lecture is a cooperative endeavor between the New York State Department of Health and the Medical Society of the State of New York.

Wyoming County

The officers for 1942 are as follows: president,

Dr. Paul A. Burgeson, of Warsaw, vice-president, Dr. G. A. McQuilkin, of Varysburg, secretary-treasurer, Dr. Oliver T. Ghent, of Warsaw, delegate to state convention, Dr. Henry S. Martin, of Warsaw, alternate, Dr. G. Stanley Baker, of Castile, board of censors, Dr. Mary T. Greene, of Castile, Dr. McQuilkin and Dr. L. Hayden Humphrey, of Silver Springs.

SECTION ON HEALTH EDUCATION AND MEDICINE OPENED BY AMERICAN FILM CENTER

A section on films in health education and medicine has been established at the American Film Center according to an announcement by Donald Slesinger, director of the Center, at its office, 45 Rockefeller Plaza, New York City. Dr. Adolf Nichtenhauser is in charge of the section.

The new section is a clearinghouse and information center on the use and production of health education and medical films.

Through this section the American Film Center will evaluate existing health films in collaboration with health experts and publish, from time to time, lists of recommended films. Cooperation with the many groups using health films will be sought in order to create a solid economic basis for their production. A long-range production program will be developed in collaboration with competent agencies.

Attention will also be paid to the technical medical film, especially with regard to its use in medical schools. From its beginning the Ameri-

can Film Center has cooperated with medical and scientific agencies, such as the Wistar Institute of Anatomy and Biology in Philadelphia and various hospitals in New York and New England, in the study and production of films.

Dr. Nichtenhauser has been working in educational cinematography for many years. Before joining the Center he was on the staff of the National Tuberculosis Association and of the New York Tuberculosis and Health Association, where he worked on health films. His production associate, Ensign Warren Sturgis, is on leave with the Naval Medical School.

The Section on Health and Medical Films has received a three-year grant from the Rockefeller Foundation.

The American Film Center, an educational organization supported by the Rockefeller Foundation, was established in the summer of 1938. Among the members of its Board is Kenneth D. Widdemer, director of the Committee on Neighborhood Health Development.

The thirty-eighth annual meeting of the Phi Delta Epsilon medical fraternity will take place at the Waldorf-Astoria Hotel, New York City,

December 30 and 31. Dr. Morris Fishbein, editor of the *J.A.M.A.*, will be one of the banquet speakers.

Hospital News

See Emergency Notice on Page 2393

Hospitals and Priorities

IN THE November issue of the *Modern Hospital* there appears an up-to-date summary of the hospital and priorities situation. Commenting, editorially, the same publication says

"The federal government has expressed, through various officials, a desire to do everything possible to maintain the service of hospitals during the current emergency. 'Everything possible' must be interpreted in terms of the current situation and the judgment of different officials as to the amount of effort that will be required to defeat Hitler. The Supply Priorities and Allocation Board is apparently determined not to underestimate the job it faces

"We in the hospital field must not underestimate it either. We must make every possible effort to cooperate in the present national effort and to continue to merit the preferential treatment that we are receiving at the hands of the government

"The resolution on this subject adopted at the recent Atlantic City convention should become the guide of all hospitals. This resolution pledged the hospitals to analyze their needs carefully (eliminating all wanted items that are not strictly necessary), to eliminate all possible waste, to keep inventories down to actually indicated needs, and to give full cooperation in the national interest during this time of emergency

"The maintenance and repairs order was recently amended by O P M to give hospitals an A-10 rating for all needed operating supplies. Since hospitals are only one of 22 large industries that are included in this order, it is impossible for federal officials to maintain minute control over the use of the plan. Hospitals are, therefore, put on their honor to use the plan only when necessary

"If some hospitals abuse the special privileges extended to them, the result will be greater difficulty for all institutions—closer control by federal officials and more paper work for the hospitals.

"There is a war to win and we in the hospital field are determined to do our part to see that it is won as quickly and effectively as possible. This is the only humanitarian viewpoint possible."

Newsy Notes

Dr William T Clark was unanimously elected to succeed the late Dr Walter S Goodale as superintendent of Meyer Memorial Hospital in Buffalo. Dr Clark has been associated with the hospital for sixteen years and has served as assistant superintendent since 1939

More than 100 executives of eastern state hospitals attended the New York Institute for Hospital Administrators held this fall at the Cornell Medical College in New York City

The superintendent of the Mount Vernon Hospital, Arthur B Solon, informed the Board of Managers at a meeting last month that the average price of hospital commodities in September was 19 per cent higher than in the same month a year ago, food, 73 per cent, cotton goods, 43 per cent, dairy products, 34 per cent, canned fruits, 31 per cent, canned vegetables, 30 per cent, surgical dressings, 18 per cent, and drugs and chemicals, 2 per cent.

In an address before the New York State Nurses Association held in Brooklyn last month, Miss Caroline Falls, director of the defense program of the association, said that in case of war 20,200 registered nurses in New York State would be ready to serve in the armed forces of the country. She reported that last December 60,000 questionnaires were sent by the association to as many registered nurses under the sponsorship of the United States Public Health Service. Of the 32,000 who responded, 14,000 indicated their willingness to serve in the Army and 6,200 in the Navy in case of war

Dr Henry Wigerson, former New York University instructor in surgery, left last month for Palestine where he will be head neurosurgeon in the Rothschild-Hadassah University Hospital.

Thirty per cent of the patients at Beth Israel Hospital in New York City are men and women who were cast into concentration camps and jails after Hitler rose to power in Germany. The hospital celebrated its fiftieth anniversary last month. Its initial capitalization was \$10 contributed by forty Jewish merchants, tailors, and peddlers who decided to care for the neglected sick among the 250,000 Jews—many of them immigrants—who lived in a square-mile area along the narrow, crooked streets of the lower East Side

A reversal of hospital reports generally seen today is that of the Frederick Ferris Thompson Hospital in Canandaigua, which says that the hospital income per patient day showed an increase and the cost per day went down in the year. Whereas the average income per patient day was \$4.17 plus in 1940, it was \$4.42 in 1941, and the cost per patient day decreased from \$4.91 last year to \$4.83 in the current year

Only 9 of the 291 births in the City of Corning occurred outside the Corning Hospital during the first six months of 1941. A new, badly needed delivery table has just been installed. The hospital has an unusually low rate for maternity care—\$45 for ten days in a private room, which includes everything.

Nearly 10 per cent of all the hospitals in the United States offering courses to train volunteer nurses' aides are located in Westchester, according to a recent announcement by Fiorello H. La Guardia, Director of the Office of Civilian Defense

Hospital rates are going up. That is the crystallized conclusion drawn from a quick nation-wide survey made recently by the *Modern Hospital* to determine the trend in the field as a whole.

Those that have acted during the last six months have raised their rates, on an average, 50 cents a day. Laboratory, x-ray department, and operating room fees, flat rates for maternity cases, charges for drugs and dressings, all have been increased in many hospitals to offset a budget deficit.

Dr. Fraser D. Mooney, superintendent of the General Hospital, Buffalo, has been re-elected president of the Western New York Hospital Council. Speaking at the Council's annual round table was Robert I. Millonzi, assistant counsel of the New York State Department of Agriculture and Markets, who urged the hospitals to pool their physical equipment, ideas, and personnel as their contribution to the defense program. Dr. James R. Borzilleri, president of Columbus Hospital, told the same meeting that "hospitals, to survive as free institutions, must be ever alert to maintain control of themselves, while gracefully accepting the inevitable increasing government subsidies."

Dr. Irvin Abell, in making the announcement of the 1941 list of approved hospitals, said that "hospitals are more appreciated today than ever before, doubtless because the nation in mobilizing its resources for defense has recognized the fundamental value of a high average of health."

On October 30 Blue Cross Day was observed throughout the country. The occasion marked the enrollment of seven and a half million American workers and their families as hospital service subscribers.

The new library at the South Nassau Communities Hospital in Oceanside was recently dedicated to Miss Mary Pearson, superintendent of the institution.

Miss Marian G. Randall has been appointed by Mayor La Guardia as nursing consultant in the Medical Division of the Office of Civilian Defense. Miss Randall is on leave of absence from the Henry Street Visiting Nurse Service.

Improvements

The superintendent of the General Hospital of Syracuse, Carl P. Wright, had no sooner re-

ceived the green light from Washington than he had the building committee on the phone and an impromptu ground-breaking took place for the new wings of the hospital for which some 5,900 Syracusans pledged nearly half a million dollars last spring. The construction had been delayed because of the lack of steel. The hospital bed shortage has been so acute that in some cases men have had to be put in the maternity ward.

In Westfield a campaign has just been conducted to raise funds for a new hospital. Among the pledges are work contracts that bind the signers to a stated amount of labor in revamping the building or grounds. Chief among the signers of these pledges are welfare cases unable to give money.

The new \$75,000 addition to Butterfield Hospital in Cold Spring will be completed about the first of the year.

St. Mary's Hospital in Amsterdam has a new deep-therapy equipment added to the x-ray department.

Construction of a new wing to the present Ossining Hospital at an expenditure of about \$40,000 is now being considered.

An electrocardiograph has been presented as a gift to the Nathan Littauer Hospital in Gloversville by Jacob Zuckerman, glove manufacturer of that city.

Plans have been set in motion by the Board of Trustees of the Geneva General Hospital to secure a loan of \$68,000 from the Federal Government for the rehabilitation of the second floor of the old east wing of the building.

A new dispensary building at Kings County Hospital in Brooklyn, costing approximately \$1,000,000, was recently dedicated. The new dispensary will enable its professional staff to treat patients under ideal conditions. Additional units are planned for Harlem, Lincoln, Coney Island, and Cumberland hospitals, besides increases in present facilities for Bellevue, Queens General, and Morrisania hospitals.

Huntington Hospital has an iron lung, recently secured through the National Foundation for Infantile Paralysis.

The Ilion Hospital Board agreed to accept a federal fund allocation of \$80,000 for the con-

struction of an \$110,000 addition to the hospital which would double its capacity

On October 27, ground was broken for the new Nightingale Hospital, an institution for the treatment of cancer, at 163rd Street and Fort Washington Avenue. Mayor La Guardia and Dr. Nicholas Murray Butler, president of Columbia University, were the principal speakers. The hospital will be built and maintained by the city and will be staffed by Columbia Uni-

versity and the Presbyterian Hospital. The new unit in the city's hospital system will cost an estimated \$2,218,500 and is scheduled for completion in March, 1943. It will have a capacity of 315 beds and will replace the old New York City Cancer Institute on Welfare Island and the Cancer Clinic on East Fifty-ninth Street.

The \$21,000 addition to St. John's Riverside Hospital in Yonkers was completed last month.

Prize Essays

THE Merritt H. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, April 27, 1942, in New York City.

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merritt H. Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed with the name of the Prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1942, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York.

CHAS. GORDON HEYD, M.D., Chairman
Committee on Prize Essays

THE APPROVED LABORATORY IN NEW YORK STATE IN RELATION TO CHEMOTHERAPY

JOHN K. MILLER, M D, Albany, New York

THE role of the laboratory in the management of infectious diseases has become increasingly important with the development of effective treatment by sulfanilamide and its derivatives. It is fortunate, therefore, that laboratory facilities are already available in the state through the system of approved laboratories. The joint efforts of the Division of Laboratories and Research and the New York State Association of Public Health Laboratories, a separate, independent organization whose members are elected from qualified representatives of the approved laboratories, have been directed toward the maintenance of high standards through the provision of well-qualified directors and pathologists in charge, by the establishment of uniform technical procedures, and by research leading to the introduction of new and improved methods. From time to time the Association has prepared leaflets on laboratory aids in the diagnosis of a number of diseases including pneumococcal and streptococcal infections.

Laboratory procedures that contribute to effective chemotherapy by sulfanilamide and its derivatives can be divided into three groups: (1) methods of isolation and identification of the inciting agent, (2) a quantitative chemical determination of the amount of the drug in body fluids, (3) procedures for the detection of the toxic effects of the drug. A proper evaluation of the results of these tests requires a determination of the pretherapeutic status of the cellular constituents of the blood, the content of the urine, and the renal function.

Identification of Inciting Agent

Chemotherapy does not remove the necessity for determining the inciting agent of an infection. In fact, identification of the invading microorganism is a definite aid not only in the decision to use chemotherapy but also in the choice of the sulfonamide that acts most effectively in the particular infection. For example, these drugs have no demonstrable action in pneumonias of virus origin, but sulfapyridine, sulfadiazine, and sulfathiazole are effective in pneumococcal pneumonias, and sulfathiazole and sulfadiazine are effective in staphylococcal pneumonias. In mixed infections of the urinary system a bacteriologic differentiation of the microorganisms present is important. Most of the common incitants are susceptible to sulfanilamide but, of the compounds now available, sulfathiazole and sulfadiazine are the only ones that inhibit the staphylococcus and entero-

coccus—for example, *Streptococcus fecalis*. One of the most significant early steps in effective chemotherapy is, thus, the responsibility of the laboratory—namely, the attempt to isolate and identify the causative microorganism in the exudates or other material from the lesion in the blood, spinal fluid, or urine. If the incitant is identified, the patient would not be subjected to the toxic action of a drug that is not effective in his particular infection.

It is important also to know the type of the incitant of an infectious disease for which there is type-specific serum that can be used in cases failing to respond to a drug or in which combined serum therapy and chemotherapy are advisable. In pneumococcal pneumonias a specimen of sputum for pneumococcus typing should be obtained before chemotherapy is started. This avoids delay if serum is to be administered later. Moreover, determination of type may be difficult after chemotherapy is instituted. Similarly, it is essential to know the group to which the streptococcus belongs, since strains of certain groups are more easily inhibited by sulfanilamide than are others.

Examination of a blood culture is another valuable diagnostic procedure in the management of an infectious process. It serves as a check on the bacteriologic diagnosis of material from the primary lesion. More important, however, is the fact that the presence of a bacteremia influences the course of therapy, as well as the prognosis and the probability of complications. It is especially desirable to obtain a specimen of blood for culture before starting chemotherapy, otherwise blood from patients receiving one of the sulfonamides might contain sufficient drug to retard the growth of bacteria in that blood when it is inoculated into mediums.

Chemical Determination of the Amount of Drug in Body Fluids

Once the proper sulfonamide has been selected and therapy commenced, a quantitative chemical determination of the concentration of the drug in the blood is valuable in controlling adequate dosage and in avoiding toxic effects. In meningitis, determinations on both blood and spinal fluid are important because there may be an effective level in the blood but not in the spinal fluid. Both the free and total concentration of drug should be estimated. The difference indicates the amount that has been acetylated. It is the acetyl compound, occurring to a greater extent with sulfapyridine and sulfathiazole, which is associated with the injurious formation of crystals and uroliths in the urinary system.

The best method of quantitative determination of the sulfonamides is that of Marshall.¹⁻³ The details of the procedure in mimeographed

form have been distributed to the directors of the approved laboratories whose facilities for carrying on this work are being surveyed by the Division of Laboratories. It should be noted that under the conditions of the method certain compounds—such as phenacetin, aniline, and such drugs as procaine, epinephrine, ephedrine, and certain amino acids (tryptophan)—will produce a color interfering with the test.^{4,5} Therefore, a determination should not be done on blood from patients receiving such drugs.

Detection of the Toxic Effects of the Drugs

During the course of therapy with sulfonamides, certain toxic effects may occur. Anemia, leukopenia, and agranulocytosis have been noted most frequently following treatment with sulfanilamide, with sulfapyridine and sulfathiazole, hematuria and impairment of renal functions occur more often. However, each of the sulfonamides may produce any of these toxic effects. With the exception of agranulocytosis, these manifestations can usually be discovered by daily clinical observation. Certain simple laboratory procedures, however, facilitate the early detection of toxicity. Hemoglobin determination and erythrocyte count for the presence of anemia, total and differential leukocyte count for the detection of agranulocytosis, examination of the urine with particular attention to the presence of red blood cells and crystals of acetylated sulfonamides indicative of damage to the urinary tract, and measurement of the total daily urinary output as a check on renal function. Suspected impairment of the renal function should be confirmed by the determination of the nonprotein nitrogen in the blood. If the initial level is high or if hematuria or anuria occurs, it may be necessary to have this determination made daily.

The frequency of tests during therapy depends on the intensity and duration of treatment, toxic manifestations, and therapeutic response. The interval should be decided by the clinician with regard for the limitation of laboratory facilities available to him. Ordinarily, the concentration of the drug in the blood should be determined within the first twelve to eighteen hours of therapy, particularly when there has been no response to treatment, if the infection is severe and the patient is receiving intensive therapy, determination should be made daily thereafter. A hemoglobin estimation and a total and differential leukocyte count should be done at one- to three-day intervals, especially during the first week of therapy. Since agranulocytosis usually occurs after the fourteenth day of treatment, daily leukocyte counts should be done when therapy is continued for two weeks or longer. Patients receiving sulfapyridine or sulfathiazole should have a determination of the total daily urinary output and an examination of urine, particularly the urinary sediment, every other day. There is less need to examine the urine when sulfanilamide or sulfadiazine is used. Examinations of the blood and urine at weekly intervals usually suffice for

ambulatory patients receiving the average course of therapy for such an infection as gonorrhea. Failure to improve under chemotherapy when there is adequate concentration of drug in the blood and an absence of detectable complications is an indication for additional bacteriologic studies in a search for a possible secondary invading microorganism.

In view of the increasing use of sulfonamides, the Division of Laboratories and the Association are investigating certain new procedures which they believe will aid in the management of infectious diseases treated by the sulfonamide derivatives. The work of Finland⁶ and Janeway⁷ and studies by the Division of Laboratories^{8,9} indicate that para-aminobenzoic acid or its sodium salt inhibits the bacteriostatic action of sulfonamides on microorganisms in blood inoculated into culture mediums. This allows the detection of a bacteremia that might otherwise be hidden by the action of the sulfonamide. The results of these observations will shortly be made available to the approved laboratories. A simple rapid method is needed to estimate the resistance of a strain of microorganism to a chemotherapeutic agent. A comparative study of several methods¹⁰⁻¹² is being made, but it is too early to evaluate the results. With such tests, differences in the capacity of the sulfonamides to inhibit the growth of a strain could be shown. Likewise, differences in the resistance of various strains of an incitant and the acquisition of strain resistance during therapy could be detected. Such information, if evaluated with regard for differences between conditions in vitro and in vivo, would be of value in the management of chemotherapy.

Thus it is hoped that by these investigations and future research the scope of the laboratory services of the state, through the collaboration of the central state laboratory with the local approved laboratories, may be extended in these new fields.

THE APPROVED LABORATORY IN NEW YORK STATE IN RELATION TO CHEMOTHERAPY

JOHN K. MILLER, M D, Albany, New York

THE role of the laboratory in the management of infectious diseases has become increasingly important with the development of effective treatment by sulfanilamide and its derivatives. It is fortunate, therefore, that laboratory facilities are already available in the state through the system of approved laboratories. The joint efforts of the Division of Laboratories and Research and the New York State Association of Public Health Laboratories, a separate, independent organization whose members are elected from qualified representatives of the approved laboratories, have been directed toward the maintenance of high standards through the provision of well-qualified directors and pathologists in charge, by the establishment of uniform technical procedures, and by research leading to the introduction of new and improved methods. From time to time the Association has prepared leaflets on laboratory aids in the diagnosis of a number of diseases including pneumococcal and streptococcal infections.

Laboratory procedures that contribute to effective chemotherapy by sulfanilamide and its derivatives can be divided into three groups: (1) methods of isolation and identification of the inciting agent, (2) a quantitative chemical determination of the amount of the drug in body fluids, (3) procedures for the detection of the toxic effects of the drug. A proper evaluation of the results of these tests requires a determination of the pretherapeutic status of the cellular constituents of the blood, the content of the urine, and the renal function.

Identification of Inciting Agent

Chemotherapy does not remove the necessity for determining the inciting agent of an infection. In fact, identification of the invading microorganism is a definite aid not only in the decision to use chemotherapy but also in the choice of the sulfonamide that acts most effectively in the particular infection. For example, these drugs have no demonstrable action in pneumonias of virus origin, but sulfapyridine, sulfadiazine, and sulfathiazole are effective in pneumococcal pneumonias, and sulfathiazole and sulfadiazine are effective in staphylococcal pneumonias. In mixed infections of the urinary system a bacteriologic differentiation of the microorganisms present is important. Most of the common incitants are susceptible to sulfanilamide but, of the compounds now available, sulfathiazole and sulfadiazine are the only ones that inhibit the staphylococcus and entero-

coccus—for example, *Streptococcus fecalis*. One of the most significant early steps in effective chemotherapy is, thus, the responsibility of the laboratory—namely, the attempt to isolate and identify the causative microorganism in the exudates or other material from the lesion in the blood, spinal fluid, or urine. If the incitant is identified, the patient would not be subjected to the toxic action of a drug that is not effective in his particular infection.

It is important also to know the type of the incitant of an infectious disease for which there is type-specific serum that can be used in cases failing to respond to a drug or in which combined serum therapy and chemotherapy are advisable. In pneumococcal pneumonias a specimen of sputum for pneumococcus typing should be obtained before chemotherapy is started. This avoids delay if serum is to be administered later. Moreover, determination of type may be difficult after chemotherapy is instituted. Similarly, it is essential to know the group to which the streptococcus belongs, since strains of certain groups are more easily inhibited by sulfanilamide than are others.

Examination of a blood culture is another valuable diagnostic procedure in the management of an infectious process. It serves as a check on the bacteriologic diagnosis of material from the primary lesion. More important, however, is the fact that the presence of a bacteremia influences the course of therapy, as well as the prognosis and the probability of complications. It is especially desirable to obtain a specimen of blood for culture before starting chemotherapy, otherwise blood from patients receiving one of the sulfonamides might contain sufficient drug to retard the growth of bacteria in that blood when it is inoculated into mediums.

Chemical Determination of the Amount of Drug in Body Fluids

Once the proper sulfonamide has been selected and therapy commenced, a quantitative chemical determination of the concentration of the drug in the blood is valuable in controlling adequate dosage and in avoiding toxic effects. In meningitis, determinations on both blood and spinal fluid are important because there may be an effective level in the blood but not in the spinal fluid. Both the free and total concentration of drug should be estimated. The difference indicates the amount that has been acetylated. It is the acetyl compound, occurring to a greater extent with sulfapyridine and sulfathiazole, which is associated with the injurious formation of crystals and uroliths in the urinary system.

The best method of quantitative determination of the sulfonamides is that of Marshall.¹⁻³ The details of the procedure in mimeographed

establish plaintiff's case, first, since they failed to state the facts as proved and, second, and more important, they failed to establish that anything that was done or left undone caused the death of the patient.

The high court ruled that the action had been properly disposed of upon the trial and in its opinion stated, in part, as follows

"It is not only the physician's duty to devote to his patient his best skill and attention, but not to leave a patient precipitately, without making arrangements which might be reasonably concluded to accomplish favorable results.

"However, there are other rules which are as sound as those relating to the doctor's duty. One is that the doctrine of *res ipsa loquitur* has no place in a case of this nature. A mere failure to effectuate a cure does not raise the presumption of want of proper care, skill or diligence upon the part of a physician. In the instant case, insofar as the proof adduced by appellants concern it, the theory is that Mrs. W died very soon after the departure of the attending physicians, hence negligence.

"Counsel for appellant lays down the premise that the only question to be answered is 'whether or not the appellee was guilty of negligence in the practice of this case,' and we agree, but the real question is, whether or not the doing of anything by the doctors, or the leaving of anything undone which is required of a physician when he undertakes the task, was the proximate cause of the death of Mrs. W. Accepting the testimony of the lay witnesses to the fullest extent, accompanied by the expert testimony of Dr. M, we fail to find any proof that death was due to any factor except the shock coming at a time when the patient's condition was not such as to meet it. Even if the rule of *res ipsa loquitur* applied, it is difficult to see how, under any circumstances, it could supply the absence of proof of the specific negligence charged in the case."

In concluding the Court stated

"Before plaintiff is entitled to recover, it must be shown that the defendant was negligent, that his want of skill or neglect to do something which a physician of ordinary skill would have done, resulted in death or injury."

PUBLIC EDUCATION IN MEDICAL MATTERS

is the subject of an editorial that appeared in the *New England Journal of Medicine* and which is herewith reprinted.

The Diabetes Education Program that is being sponsored by the Metropolitan Life Insurance Company is an encouraging example of public interest in good medicine. The increasing evidence that the early recognition and careful control of diabetes are important in checking the progress of the pancreatic and neurovascular lesions makes such a program particularly timely.

The economic value of good health to such an insurance company is, of course, obvious. But good public health or that of the individual is of equal value to private enterprise. Loss of work due to ill health is an economic burden to almost all industry. The vast sums of money spent annually by the American people on life and sickness insurance provide evidence concerning the value that they have long placed on life and health.

Advances in medical science have so increased the effectiveness of available medicine that the public's interest is shifting from insuring health and life by cash indemnities to securing health and longevity by medical care. The expansion of health programs by state departments of public health and a variety of nonprofit lay organizations reflects the public's increasing appreciation of the effectiveness of modern medicine.

The National Health Conference and the recent National Nutrition Conference were reflections of public awareness and interest. The federal government has responded through the programs of the United States Public Health Service, of the Maternity and Child Welfare Di-

vision of the Department of Labor, and of the National Health Institute at Bethesda, Maryland. This increased awareness is creating an increased demand for medical care. To finance this care, a variety of plans for voluntarily distributing and budgeting the costs of medical care are developing throughout the country. Although it is not widespread, there is even some demand for compulsory health insurance. Insofar as the layman's medical education is good and the plans for budgeted health services are sound, the medical profession, as well as the public, will benefit. The result should be more and better medicine more widely and, therefore, with present economic trends, better paid for in the long run.

So far so good, and the medical profession should indeed be happy. But there are, of course, many who will turn the public's interest in medicine to their personal advantage. For every educational program like that sponsored by the Metropolitan Life Insurance Company for better health, there will be one hundred programs on the radio and in the press sponsored by commercial organizations for the sale of unneeded or worthless medication. The same American advertising genius that has popularized alkalinizing, laxating, and antihistaminic remedies apparently is taking over the newly cultivated fields of vitamin and hormone therapy. As it does so, the money that the public should spend for effective health and medical services will be squandered to such an extent that sums spent on the trial-and-error method of establishing workable insurance schemes will seem inconsequential. But no matter what becomes of the money, the medical profession in the end will pay the bill so the public will be happy anyway.

LORENZ J. BROSNAN, Esq

Counsel, Medical Society of the State of New York

Wrongful Death Case—Failure of Proof

THE highest court of one of the southern states recently handed down its decision in an interesting case in which it was sought to impose liability upon two physicians by reason of the death of a patient following childbirth.* The action was brought by the plaintiff as administrator of the deceased to recover damages for the death of the patient against Dr T and Dr P.

It seems from the proof on the trial that previous to the day of the delivery of the patient arrangements had been made for Dr T to attend her, and on that day he was called a distance of five miles and arrived at the home at 7 30 A.M. He was told that the woman had been suffering from convulsions and promptly gave her a "shot of medicine from a glass container." He examined her heart and blood pressure. As testified to on the trial by the plaintiff's lay witnesses, Dr T realized the situation was serious and called in a Dr P, who promptly arrived and was told of what had developed. A hospital was considered, but as the nearest one was 30 miles away, the doctors proceeded with the delivery. Chloroform and other drugs were used, and by means of forceps the child was delivered alive. The doctors stayed with the woman for over two and a half hours, including a period of forty-five minutes after delivery. The child lived, but the mother died shortly after the doctors left.

Certain relatives and neighbors testified that Dr T had remarked, upon learning of the convulsions, that he doubted the mother would be saved, and they expressed an opinion that he left too soon after the delivery. It was further stated upon the trial that the doctors left the patient in the charge of relatives and of her mother with instructions as to care and gave them directions as to how to reach him if needed. He was called back in a short time, but the patient was dead on his arrival.

The foregoing was, in substance, the testimony of the lay witnesses called by the plaintiff, except that one of them said that on leaving the patient Dr T remarked that "she was getting along all right."

The plaintiffs called a Dr M as an expert witness. His answer to general questions about chloroform was that its use depended on the symptoms and would have to depend on things within the knowledge of the doctor in attendance. However, the answer "No" was given to the following question by Dr M: "From your general practice and from your general knowledge of practice in this county, I'll ask you if it would be regarded as ordinary skill and an ordinary way to practice medicine in this county, if called upon to attend a mother in childbirth, and you found she was suffering from spasms and was

unconscious, and you began to administer medicine that would eventually produce unconsciousness, and continue to use that medicine, for instance, chloroform, which would tend to produce more unconsciousness and make the patient unconscious entirely, and in that condition, after the birth of the child, you would walk off and leave the mother in that condition, is that considered ordinary skill?" The same doctor was also asked "In labor cases, when you attend a patient and they were unconscious when you want to see them, and you used medicine to put them to sleep in order to relieve suffering and aid in childbirth, is it customary to leave a patient in that condition when they are suffering and flooding to such an extent that it was dangerous and liable to result in death in any case?" His answer to the latter question was "I don't know the general practice, all I can say is that it is not my mode of practice."

The version given upon the trial by Dr T was considerably different and much more explicit. He told of failure of the patient to come in for prenatal care in response to instructions. He testified that upon arriving he had found that the patient was in a convulsion, already having had two such attacks. He gave morphine and, when another convulsion was observed, called in Dr P to assist. They found more dilatation necessary and administered medication. Dr P handled the forceps and Dr T gave chloroform to prevent further convulsions. After the delivery, according to the testimony of Dr T, he took charge of the mother. Examination revealed the uterus properly contracted, and he remained in attendance for an hour and a half. He administered pituitary to control bleeding and regulate contraction. On leaving, he administered a heart stimulant.

He stated that when he arrived in the first instance he realized the serious condition of the patient but gave as his opinion that it would have been too dangerous to remove the patient to a hospital because of the long distance to be traveled. He attributed the death to shock due to eclampsia, which had brought on the convulsions. Dr T testified that he and his associate had done everything possible for the patient and that remaining in attendance would not have saved her. He stated that usual and customary practices had been followed throughout. Dr P corroborated the testimony of Dr T.

The case was dismissed as to Dr P and, after all testimony had been given, the Court directed a verdict in favor of the defendant Dr T. The plaintiff took an appeal from the decision as regarded Dr T only.

Upon appeal the plaintiff relied in great part upon the answers made by Dr M to the two questions quoted above. The Appellate Court, however, ruled that they were not sufficient to

Woman's Auxiliary

To the Medical Society of the State of New York

CHRISTMAS again! It is a happy coincidence that we reach the half-way mark in our Auxiliary year at Christmas time. Renewing within ourselves the spirit of the season we pause to "look at the record" comparing our hopes and plans with our accomplishments.

As we push ahead in our auxiliary work toward our goal let us carry with us the Spirit of Christmas while we assist our tireless Healers of the Body to spread to all people a knowledge of Health without which there is no peace or happiness. To each member of our Auxiliary, Greetings and the old, old wish, Joy at Christmas

Your president,

VIRGINIA ADAMS

County News

Albany At an open meeting recently held at the Joseph Henry Memorial, Dr Harold Street gave a talk on "Nutrition." Preceding the talk a business meeting was held. Mrs. Darwin A. Bruce was chairman for the social hour which followed, assisted by Mesdames Louis J. De Russo, Philip Hacker, Joseph Heim, Charles A. Perry, Simon Propp, Walter A. Reynolds, Charles E. Stott, Joseph I. Schleinstein, Raymond Kircher, Emerson C. Kelly, and John Cetner.

Columbia. At a banquet opening the Christmas Seal Sale for County Tuberculosis work, many of the doctors and their wives enjoyed hearing Dr. Peter Irving, general manager and executive secretary of the New York Medical Society. Dr. Irving stated that unwillingness and reluctance on the part of citizens to take tests because of fear and expense was one of the greatest problems practicing physicians and health departments have to face. Expense is of no small moment and work is under way to provide for more tests through tax funds, he said. Dr. Irving was clear to state that this does not mean the support of socialized medicine.

Dr. Edward S. Godfrey, Jr., state commissioner of health, and Dr. Kendall Emerson, director of the National Tuberculosis Association, were also speakers at this meeting.

At the November meeting a luncheon was held at the General Worth Hotel in Hudson. Those present were Mrs. Robert L. Boverhan, Mrs. Hugh G. Henry, Mrs. Harry A. Pattison, Mrs. Ralph F. Spencer, Mrs. John L. Edwards, Mrs. Charles L. Nichols, Mrs. William D. Collins, Mrs. W. L. J. McDonald, Mrs. O. H. Bradley, Mrs. Henry C. Galster, Mrs. Caldwell B. Esselstyne, Mrs. Sherwood V. Whitbeck, Miss Mary G. Whitbeck, Mrs. Heinz Salm, Mrs. Leonard M. Neisen, Mrs. Henry J. Noerlung, Sr., and Mrs. Leonard D. Carpenter.

At the request of Mrs. Bowerhan, president, Mrs. Henry, president-elect, presided. During the business meeting, Mrs. Pattison, Mrs. Salm, Mrs. McDonald, Mrs. Spencer, and Miss Whitbeck signified their willingness to attend and help on committees for the State Convention.

Dr. Ralph F. Spencer, president of the county

medical society, was the guest speaker. He stressed the importance of lay education as regards cancer and the valuable part that the doctors' wives can play in this work. Dr. Spencer said that the New York Legislative Cancer Survey Commission has pointed out that there are three main points of attack for the solution of the cancer problem: (1) lay education, (2) professional education, (3) increase in local facilities for diagnosis and treatment of cancer. Lay education is by far the most important, he told the group. Through it the fear and dread of the disease may be overcome and the pessimistic attitude toward cancer extinguished.

Montgomery Auxiliary hears project. Mrs. E. A. Bogdan addresses the meeting—giving a talk on "Health Education." Mrs. P. J. Fitzgibbons presided at the tea table. This meeting was held at the Amsterdam City hospital. Members from various city and county clubs, a number of public school teachers, and nuns from St. Stanislaus and St. Mary's schools were present. Mrs. Bogdan said that the business of health education was the cornerstone upon which the auxiliary was founded and that the National Medical Auxiliary has adopted as its slogan, "*Hygeia* for Health."

She then explained the importance of a health magazine for nonmedical readers, a periodical through which the public might be enlightened in medical science. This need was recognized as early as 1920 by many physicians affiliated with the American Medical Association. She also said the possibility of such a publication became more definite the following year and a magazine called *Hygeia*, a name chosen because it is a symbol of medical science and preventive medicine, was first issued in April, 1923.

Mrs. Bogdan went on to explain that it was the aim of the auxiliary to place this magazine in the high schools of the city, and it was also hoped to have it available in the grade schools. She urged cooperation of Parent Teacher Associations in this important undertaking.

Nassau. On December 16 at the Nassau Hospital Auditorium at 8:30 P.M. the auxiliary will have its Christmas party.

On January 27 at the same place at 8:45 P.M., moving pictures will be shown by Eugene H. Coons.

Rensselaer. The medical unit met at the Y.W.C.A. in Troy. Scientific advances in medicine in the last decade, especially in relation to their economic aspects, were discussed by Dr. John O. Sibbald, president of the Rensselaer County Medical Society. Dr. Sibbald discussed public health trends and commented upon the symposiums that the society has conducted during the year to acquaint medical men with current events in the field of economics and world politics.

Women of the auxiliary, he said, can aid their husbands by encouraging them to take an interest in significant events outside the field of medicine.

NATURE—THE GREATEST SHOW ON EARTH

The New York World's Fair of 1940 haggred of playing host to some fifteen million visitors The largest crowd attending a sports event numbered about 160,000 A hit play on Broadway performs to a half a million persons in a year

Except for the World's Fair, perhaps, all more publicized attractions have hut small-time carnival crowds in comparison to the total Americans visiting their National Parks in recent years

In 1940, for example, sixteen million, seven hundred and fifty-five thousand were officially recorded as the total attendance at such points of interest In 1941, the number increased by twenty-six per cent (official year ending September 30) to reach an all-time high of more than twenty-one millions

This growing interest in the wonders of nature in our own country is even more impressive when compared with records just eight years ago when only three and one-half million Americans paid any enthusiastic attention to the tremendously interesting marvels here in this country

Other indications of the magnitude of the attendance may be grasped from the fact that Park Service areas were visited by sixteen per cent of the population of the United States Travel to the twenty-six units of the park system alone reached more than eight and a third millions for the past official year

Leading this parade were the Great Smoky Mountains in Tennessee and North Carolina with 1,247,029 Shenandoah, previous year's leader, was second with 1,054,479 and Rocky Mountain was third with 685,393 Yosemite and Yellowstone were close runners-up with over 500,000 each

Other Park Service areas, not listed as national parks, that reported breaking the half million mark were Fort McHenry National Monument and Historical Shrine, Colonial National Historic Park, Gettysburg National Military Park, Lincoln Memorial and Washington Monument in the District of Columbia, Boulder Dam National Recreation Area, and the Blue Ridge National Parkway

(Continued on page 2461)

FALKIRK IN THE RAMAPOSS

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES Falkirk has been recommended by the members of the medical profession for half a century

Literature on Request

ESTABLISHED 1889

THEODORE W NEUMANN, M.D., Phys in-Chg
CENTRAL VALLEY, Orange County, N. Y.

RIVERLAWN SANITARIUM

FOUNDED 1893

A conveniently situated Sanitarium offering complete facilities for the treatment and care of MENTAL AND NERVOUS CASES and ALCOHOLIC AND DRUG ADDICTIONS. We extend full cooperation to the Physicians.

CHARLES B. RUSSELL MD, Med Dir

45 Tolowe Ave. PATERSON, N J. Army 4-2342

THE MAPLES INC, ROCKVILLE CENTRE, L. I.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets, and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates \$18 to \$35 Weekly. MRS. M. E. MANNING, Supt. - TEL: Rockville Centre 3660

BRUNSWICK HOME

A Private Sanitarium

Broadway and Loudon Avenue
AMITYVILLE, L. I.—Phone: 1700, 01 02
N. Y. Office—67 W 44th Street
Tel. Murray Hill 2 8323
C. L. MARKHAM, M.D., Supt.

Convalescents, post-operative and habit cases, for the aged and infirm and those with other chronic and nervous disorders.

Separate accommodations for nervous and backward children.

Physicians' treatments rigidly followed.

HALCYON REST

754 BOSTON POST ROAD, RYE, NEW YORK

Henry W. Lloyd, M.D., Physician in Charge

Licensed and fully equipped for the treatment of nervous, mental, drug and alcohol patients, including Occupational therapy. Beautifully located a short distance from Rye Beach.

Telephone Rye 550

Write for illustrated booklet

(Continued from page 2460)

Other National Park areas that attracted a great stream of American "homeland tourists" included—Acadia in Maine, Bryce Canyon in Utah, the Carlsbad Caverns, Crater Lake in Oregon, Glacier in Montana, the Grand Canyon in Colorado, Grand Teton in Wyoming, Hawaii, Hot Springs in Arkansas, Isle Royale in Michigan, Kings Canyon in California, Lassen Volcanic in California, Monmouth Cave in Kentucky, Mesa Verde in Colorado, Mount McKinley in Alaska, Mount Ranier in Washington, Olympic in Washington, Platt in Oklahoma, Sequoia in California, Wind Cave in South Dakota, and Zion in Utah.

WHEEL CHAIRS—A PREMIUM

One of those small, hackwoodsy tabloid papers that seem to find their way somehow into homes where one expects better things—offers wheel chairs as a premium for selling subscriptions. In September, proudly proclaims the paper, two wheel chairs were awarded—one to a woman of 58 who had 265 subscriptions to her credit, and the other to a man of 34 with 250 subscriptions to his credit.

It appears a very noteworthy deed, especially when one considers that a subscription to the publication costs only twenty-five cents per year and a wheel chair is no five and dime article. In addition the paper pays the freight charge to any point in the United States.

To date, claims the paper, 1248 wheel chairs have been awarded to as many needy men and women.

BUT, and it's a large but indeed, the same charitable paper endorses (and any publication that accepts an advertisement for its readers to see and read is practically endorsing it)—endorses such items as "false teeth by mail at \$8.50 with a 90-day trial," a doctor's information free for childless wives, a medicine for varicose veins to be applied with a paint brush, as well as several different versions about "what every husband should know."

Maybe they believe in making more "cripples" for bountiful subscription premiums.

TYPING MEN

According to what young moderns are led to believe by one of the newer magazines published for their guidance—there are six types of men, viz:

Type I A turtle-neck sweater plus cereal plus a gymnasium equals the athletic he-man or Ox. He likes his gals sweet, feminine and shy.

Type II A plaid sports coat plus a swanky dinner plus a low-slung convertible equals the Big Shot—the best catch on the campus. He knows all about women so don't try a line.

Type III A blue serge vest with a watch chain plus an empty country road equals the lonely worm. You must help him over embarrassing situations.

Type IV A pork-pie hat plus a stein of foaming beer plus a booth at the Greek's equals the busy back-slapper. You must learn to feed his ego in public.

Type V An open-neck shirt plus a bottle of red wine and a hunk of baloney plus a mass meeting equals the belligerent idealist. Don't try hair bows or glamour or purple lipstick with him.

Type VI A stiff collar and string tie plus black coffee plus a desk piled high with books equals the intellectual grind. He doesn't care much for frivolities.

Married men apparently have no rating in the classifications of the younger generations, so all benedicts, especially, can settle back in their uneasy chairs and placidly watch the younger world go by.

McKINNEY'S SANITARIUM

for ELDERLY PEOPLE,
CONVALESCENTS and
CHRONIC INVALIDS

105 BRUCE AVE., YONKERS, NEW YORK
YONKERS—3265

Under medical supervision tender and devoted care in an atmosphere unusually home like. Expert dietetic and nursing service. Full cooperation with patient's personal physician.

LOUDON-KNICKERBOCKER HALL, Inc.

81 LOUDON AVENUE

Tel. Amityville 52

AMITYVILLE, N. Y.

A private sanitarium established 1836 specializing in NERVOUS and MENTAL diseases.

Full information furnished upon request

DR. BARNES SANITARIUM STAMFORD, CONN

45 minutes from N Y C via Merritt Parkway

For treatment of Nervous and Mental Disorders, Alcoholism and Convalescents. Carefully supervised Occupational Therapy. Facilities for Shock Therapy. Accessible location in tranquil, beautiful hill country. Separate buildings.

F H BARNES, M.D., Med. Supl. *Tel 4-1143

TERRACE HOUSE for ALCOHOLISM

A private sanatorium offering a specific treatment for alcoholism, formulated to relieve the craving for alcohol and with re-education working toward permanent abstinence. Homelike surroundings. Competent medical and nursing care. 16 miles from Buffalo

Moderate rates—Enquiries invited

64 Maple St. - East Aurora, N. Y. - Phone 784

WEST HILL

West 252nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous mental, drug and alcoholic patients. The sanatorium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

HENRY W LLOYD, M.D., Physician in Charge
Telephone Kingsbridge 9-8440

IN A LIGHTER VEIN

From *Parade*, the British Digest of Good Reading, we picked up the following choice items of a "grim business"

* * *

Of interest to the Neurologist

"Insomnia might bother us more than invasion. Sleeping upstairs is mainly a habit. It is just as restful to sleep downstairs if you organize it properly."

* * *

Of interest to the Psychiatrist

"The indifference of many to the most urgently reiterated advice about taking cover and staying away from windows. Those who sit at their bedroom windows, stand on their doorstep, lean over their front gates, especially during daylight raids, are taking big risks. Tell them that they are foolish and they laugh. 'Might see a dog fight,' is their excuse. They often do. No wonder foreigners look at us and tap their foreheads."

* * *

For the Gastroenterologist

"The consumption of tea which the Nazi bombers encourage is enormous during and after the raids. Tea drinking is bringing people into one another's kitchens, who a short while ago didn't know one another in the street. No bottle parties have ever been such fun as these post-raid teetotal libations."

* * *

For the Pathologist

(To be taken with a grain of salt.)
Schoolboy howler—"A therm is a microbe that gets into the gas meter and controls consumption."

For the Obstetrician

Another schoolboy howler—"Heroic couplets are a man and a woman who have many adventures and misfortunes and at last things are so bad they get married and have children."

* * *

To the Surgeon

War teaches surgeons. "It is too early to say whether victims of car and industrial accidents in the future will be helped by the lessons surgeons learn from the present war, but a look at the past, even so recent a past as the war in Spain, suggests that this may be so."

To the Medical Examiner

"The lads had presented themselves for medical examination, and Jimmy had been passed for service. Asked if he had any preference as to what he wanted to be, Jimmy replied, 'Yes.' 'Well, what would you like to be?' asked the officer. 'An ex-Serviceman with a pension,' was the answer."

And the Dietitian

"The patient was recovering from pneumonia. He had asked repeatedly for food and finally the nurse served him a mere spoonful of rice. A few moments later the patient called her and said, 'Now I want to read a little. Bring me a postage stamp.'"

SIN'S MEDICAL COLLEGE
